
pandas: powerful Python data analysis toolkit

Release 1.4.1

Wes McKinney and the Pandas Development Team

Feb 12, 2022

CONTENTS

1 Getting started	3
1.1 Installation	3
1.2 Intro to pandas	3
1.3 Coming from...	5
1.4 Tutorials	5
1.4.1 Installation	6
1.4.2 Package overview	12
1.4.3 Getting started tutorials	15
1.4.4 Comparison with other tools	61
1.4.5 Community tutorials	147
2 User Guide	149
2.1 10 minutes to pandas	149
2.1.1 Object creation	149
2.1.2 Viewing data	151
2.1.3 Selection	153
2.1.4 Missing data	158
2.1.5 Operations	159
2.1.6 Merge	161
2.1.7 Grouping	163
2.1.8 Reshaping	165
2.1.9 Time series	167
2.1.10 Categoricals	169
2.1.11 Plotting	171
2.1.12 Getting data in/out	173
2.1.13 Gotchas	174
2.2 Intro to data structures	174
2.2.1 Series	175
2.2.2 DataFrame	180
2.3 Essential basic functionality	198
2.3.1 Head and tail	198
2.3.2 Attributes and underlying data	199
2.3.3 Accelerated operations	201
2.3.4 Flexible binary operations	202
2.3.5 Descriptive statistics	211
2.3.6 Function application	220
2.3.7 Reindexing and altering labels	233
2.3.8 Iteration	243
2.3.9 .dt accessor	247
2.3.10 Vectorized string methods	251

2.3.11	Sorting	251
2.3.12	Copying	259
2.3.13	dtypes	259
2.3.14	Selecting columns based on dtype	270
2.4	IO tools (text, CSV, HDF5, ...)	273
2.4.1	CSV & text files	274
2.4.2	JSON	313
2.4.3	HTML	328
2.4.4	LaTeX	337
2.4.5	XML	338
2.4.6	Excel files	350
2.4.7	OpenDocument Spreadsheets	357
2.4.8	Binary Excel (.xlsb) files	357
2.4.9	Clipboard	358
2.4.10	Pickling	359
2.4.11	msgpack	362
2.4.12	HDF5 (PyTables)	362
2.4.13	Feather	390
2.4.14	Parquet	392
2.4.15	ORC	395
2.4.16	SQL queries	395
2.4.17	Google BigQuery	403
2.4.18	Stata format	403
2.4.19	SAS formats	406
2.4.20	SPSS formats	406
2.4.21	Other file formats	407
2.4.22	Performance considerations	407
2.5	Indexing and selecting data	411
2.5.1	Different choices for indexing	411
2.5.2	Basics	412
2.5.3	Attribute access	414
2.5.4	Slicing ranges	416
2.5.5	Selection by label	418
2.5.6	Selection by position	422
2.5.7	Selection by callable	426
2.5.8	Combining positional and label-based indexing	428
2.5.9	Indexing with list with missing labels is deprecated	429
2.5.10	Selecting random samples	431
2.5.11	Setting with enlargement	433
2.5.12	Fast scalar value getting and setting	434
2.5.13	Boolean indexing	435
2.5.14	Indexing with isin	437
2.5.15	The where() Method and Masking	440
2.5.16	Setting with enlargement conditionally using numpy()	444
2.5.17	The query() Method	445
2.5.18	Duplicate data	457
2.5.19	Dictionary-like get() method	460
2.5.20	Looking up values by index/column labels	460
2.5.21	Index objects	460
2.5.22	Set / reset index	464
2.5.23	Returning a view versus a copy	466
2.6	MultiIndex / advanced indexing	470
2.6.1	Hierarchical indexing (MultiIndex)	470
2.6.2	Advanced indexing with hierarchical index	477

2.6.3	Sorting a MultiIndex	489
2.6.4	Take methods	492
2.6.5	Index types	494
2.6.6	Miscellaneous indexing FAQ	503
2.7	Merge, join, concatenate and compare	508
2.7.1	Concatenating objects	508
2.7.2	Database-style DataFrame or named Series joining/merging	518
2.7.3	Timeseries friendly merging	539
2.7.4	Comparing objects	541
2.8	Reshaping and pivot tables	543
2.8.1	Reshaping by pivoting DataFrame objects	543
2.8.2	Reshaping by stacking and unstacking	546
2.8.3	Reshaping by melt	555
2.8.4	Combining with stats and GroupBy	557
2.8.5	Pivot tables	558
2.8.6	Cross tabulations	563
2.8.7	Tiling	565
2.8.8	Computing indicator / dummy variables	566
2.8.9	Factorizing values	569
2.8.10	Examples	571
2.8.11	Exploding a list-like column	574
2.9	Working with text data	576
2.9.1	Text data types	576
2.9.2	String methods	579
2.9.3	Splitting and replacing strings	581
2.9.4	Concatenation	585
2.9.5	Indexing with <code>.str</code>	591
2.9.6	Extracting substrings	591
2.9.7	Testing for strings that match or contain a pattern	595
2.9.8	Creating indicator variables	597
2.9.9	Method summary	598
2.10	Working with missing data	599
2.10.1	Values considered “missing”	599
2.10.2	Inserting missing data	602
2.10.3	Calculations with missing data	603
2.10.4	Sum/prod of empties/nans	605
2.10.5	NA values in GroupBy	605
2.10.6	Filling missing values: <code>fillna</code>	606
2.10.7	Filling with a PandasObject	607
2.10.8	Dropping axis labels with missing data: <code>dropna</code>	609
2.10.9	Interpolation	609
2.10.10	Replacing generic values	618
2.10.11	String/regular expression replacement	620
2.10.12	Numeric replacement	622
2.10.13	Experimental NA scalar to denote missing values	625
2.11	Duplicate Labels	629
2.11.1	Consequences of Duplicate Labels	630
2.11.2	Duplicate Label Detection	632
2.11.3	Disallowing Duplicate Labels	633
2.12	Categorical data	637
2.12.1	Object creation	638
2.12.2	CategoricalDtype	643
2.12.3	Description	644
2.12.4	Working with categories	645

2.12.5	Sorting and order	649
2.12.6	Comparisons	652
2.12.7	Operations	655
2.12.8	Data munging	657
2.12.9	Getting data in/out	665
2.12.10	Missing data	666
2.12.11	Differences to R's <code>factor</code>	667
2.12.12	Gotchas	667
2.13	Nullable integer data type	671
2.13.1	Construction	672
2.13.2	Operations	673
2.13.3	Scalar NA Value	675
2.14	Nullable Boolean data type	675
2.14.1	Indexing with NA values	675
2.14.2	Kleene logical operations	676
2.15	Chart Visualization	677
2.15.1	Basic plotting: <code>plot</code>	678
2.15.2	Other plots	680
2.15.3	Plotting with missing data	714
2.15.4	Plotting tools	715
2.15.5	Plot formatting	723
2.15.6	Plotting directly with <code>matplotlib</code>	749
2.15.7	Plotting backends	750
2.16	Table Visualization	751
2.16.1	Styler Object and HTML	751
2.16.2	Formatting the Display	752
2.16.3	Methods to Add Styles	753
2.16.4	Table Styles	754
2.16.5	Setting Classes and Linking to External CSS	755
2.16.6	Styler Functions	756
2.16.7	Tooltips and Captions	757
2.16.8	Finer Control with Slicing	758
2.16.9	Optimization	759
2.16.10	Builtin Styles	762
2.16.11	Sharing styles	764
2.16.12	Limitations	765
2.16.13	Other Fun and Useful Stuff	765
2.16.14	Export to Excel	767
2.16.15	Export to LaTeX	768
2.16.16	More About CSS and HTML	768
2.16.17	Extensibility	770
2.17	Computational tools	772
2.17.1	Statistical functions	772
2.18	Group by: split-apply-combine	777
2.18.1	Splitting an object into groups	778
2.18.2	Iterating through groups	787
2.18.3	Selecting a group	788
2.18.4	Aggregation	788
2.18.5	Transformation	796
2.18.6	Filtration	803
2.18.7	Dispatching to instance methods	804
2.18.8	Flexible <code>apply</code>	806
2.18.9	Numba Accelerated Routines	808
2.18.10	Other useful features	808

2.18.11 Examples	820
2.19 Windowing Operations	822
2.19.1 Overview	823
2.19.2 Rolling window	827
2.19.3 Weighted window	835
2.19.4 Expanding window	836
2.19.5 Exponentially Weighted window	837
2.20 Time series / date functionality	839
2.20.1 Overview	841
2.20.2 Timestamps vs. time spans	842
2.20.3 Converting to timestamps	844
2.20.4 Generating ranges of timestamps	848
2.20.5 Timestamp limitations	851
2.20.6 Indexing	852
2.20.7 Time/date components	861
2.20.8 DateOffset objects	862
2.20.9 Time series-related instance methods	878
2.20.10 Resampling	880
2.20.11 Time span representation	891
2.20.12 Converting between representations	898
2.20.13 Representing out-of-bounds spans	899
2.20.14 Time zone handling	900
2.21 Time deltas	909
2.21.1 Parsing	909
2.21.2 Operations	911
2.21.3 Reductions	915
2.21.4 Frequency conversion	916
2.21.5 Attributes	918
2.21.6 TimedeltaIndex	920
2.21.7 Resampling	924
2.22 Options and settings	924
2.22.1 Overview	924
2.22.2 Getting and setting options	925
2.22.3 Setting startup options in Python/IPython environment	926
2.22.4 Frequently used options	926
2.22.5 Available options	934
2.22.6 Number formatting	940
2.22.7 Unicode formatting	940
2.22.8 Table schema display	942
2.23 Enhancing performance	942
2.23.1 Cython (writing C extensions for pandas)	942
2.23.2 Numba (JIT compilation)	948
2.23.3 Expression evaluation via eval()	950
2.24 Scaling to large datasets	959
2.24.1 Load less data	959
2.24.2 Use efficient datatypes	961
2.24.3 Use chunking	962
2.24.4 Use other libraries	964
2.25 Sparse data structures	968
2.25.1 SparseArray	970
2.25.2 SparseDtype	970
2.25.3 Sparse accessor	971
2.25.4 Sparse calculation	971
2.25.5 Migrating	972

2.25.6	Interaction with <code>scipy.sparse</code>	974
2.26	Frequently Asked Questions (FAQ)	977
2.26.1	DataFrame memory usage	977
2.26.2	Using if/truth statements with pandas	980
2.26.3	Mutating with User Defined Function (UDF) methods	982
2.26.4	<code>NaN</code> , Integer NA values and NA type promotions	983
2.26.5	Differences with NumPy	986
2.26.6	Thread-safety	986
2.26.7	Byte-ordering issues	986
2.27	Cookbook	986
2.27.1	Idioms	987
2.27.2	Selection	991
2.27.3	Multiindexing	995
2.27.4	Missing data	999
2.27.5	Grouping	1000
2.27.6	Timeseries	1013
2.27.7	Merge	1013
2.27.8	Plotting	1015
2.27.9	Data in/out	1016
2.27.10	Computation	1022
2.27.11	Timedeltas	1023
2.27.12	Creating example data	1025
3	API reference	1027
3.1	Input/output	1027
3.1.1	Pickling	1027
3.1.2	Flat file	1030
3.1.3	Clipboard	1044
3.1.4	Excel	1046
3.1.5	JSON	1058
3.1.6	HTML	1069
3.1.7	XML	1074
3.1.8	Latex	1081
3.1.9	HDFStore: PyTables (HDF5)	1091
3.1.10	Feather	1096
3.1.11	Parquet	1097
3.1.12	ORC	1099
3.1.13	SAS	1100
3.1.14	SPSS	1101
3.1.15	SQL	1101
3.1.16	Google BigQuery	1108
3.1.17	STATA	1110
3.2	General functions	1114
3.2.1	Data manipulations	1114
3.2.2	Top-level missing data	1150
3.2.3	Top-level dealing with numeric data	1156
3.2.4	Top-level dealing with datetimelike data	1158
3.2.5	Top-level dealing with Interval data	1171
3.2.6	Top-level evaluation	1173
3.2.7	Hashing	1175
3.2.8	Testing	1176
3.3	Series	1176
3.3.1	Constructor	1176
3.3.2	Attributes	1443

3.3.3	Conversion	1444
3.3.4	Indexing, iteration	1446
3.3.5	Binary operator functions	1446
3.3.6	Function application, GroupBy & window	1447
3.3.7	Computations / descriptive stats	1448
3.3.8	Reindexing / selection / label manipulation	1449
3.3.9	Missing data handling	1450
3.3.10	Reshaping, sorting	1450
3.3.11	Combining / comparing / joining / merging	1451
3.3.12	Time Series-related	1451
3.3.13	Accessors	1451
3.3.14	Plotting	1568
3.3.15	Serialization / IO / conversion	1615
3.4	DataFrame	1616
3.4.1	Constructor	1616
3.4.2	Attributes and underlying data	1960
3.4.3	Conversion	1960
3.4.4	Indexing, iteration	1961
3.4.5	Binary operator functions	1961
3.4.6	Function application, GroupBy & window	1963
3.4.7	Computations / descriptive stats	1963
3.4.8	Reindexing / selection / label manipulation	1964
3.4.9	Missing data handling	1965
3.4.10	Reshaping, sorting, transposing	1965
3.4.11	Combining / comparing / joining / merging	1966
3.4.12	Time Series-related	1966
3.4.13	Flags	1967
3.4.14	Metadata	1967
3.4.15	Plotting	1967
3.4.16	Sparse accessor	2025
3.4.17	Serialization / IO / conversion	2026
3.5	pandas arrays, scalars, and data types	2027
3.5.1	pandas.array	2027
3.5.2	Datetime data	2031
3.5.3	Timedelta data	2063
3.5.4	Timespan data	2073
3.5.5	Period	2073
3.5.6	Interval data	2090
3.5.7	Nullable integer	2104
3.5.8	Categorical data	2109
3.5.9	Sparse data	2115
3.5.10	Text data	2117
3.5.11	Boolean data with missing values	2120
3.6	Index objects	2122
3.6.1	Index	2122
3.6.2	Numeric Index	2189
3.6.3	CategoricalIndex	2193
3.6.4	IntervalIndex	2203
3.6.5	MultiIndex	2214
3.6.6	DatetimeIndex	2235
3.6.7	TimedeltaIndex	2267
3.6.8	PeriodIndex	2278
3.7	Date offsets	2285
3.7.1	DateOffset	2285

3.7.2	BusinessDay	2292
3.7.3	BusinessHour	2298
3.7.4	CustomBusinessDay	2304
3.7.5	CustomBusinessHour	2311
3.7.6	MonthEnd	2317
3.7.7	MonthBegin	2322
3.7.8	BusinessMonthEnd	2328
3.7.9	BusinessMonthBegin	2333
3.7.10	CustomBusinessMonthEnd	2339
3.7.11	CustomBusinessMonthBegin	2345
3.7.12	SemiMonthEnd	2352
3.7.13	SemiMonthBegin	2357
3.7.14	Week	2362
3.7.15	WeekOfMonth	2368
3.7.16	LastWeekOfMonth	2373
3.7.17	BQuarterEnd	2379
3.7.18	BQuarterBegin	2385
3.7.19	QuarterEnd	2390
3.7.20	QuarterBegin	2396
3.7.21	BYearEnd	2401
3.7.22	BYearBegin	2407
3.7.23	YearEnd	2412
3.7.24	YearBegin	2418
3.7.25	FY5253	2423
3.7.26	FY5253Quarter	2429
3.7.27	Easter	2437
3.7.28	Tick	2442
3.7.29	Day	2447
3.7.30	Hour	2452
3.7.31	Minute	2458
3.7.32	Second	2463
3.7.33	Milli	2468
3.7.34	Micro	2474
3.7.35	Nano	2479
3.8	Frequencies	2484
3.8.1	pandas.tseries.frequencies.to_offset	2484
3.9	Window	2485
3.9.1	Rolling window functions	2485
3.9.2	Weighted window functions	2503
3.9.3	Expanding window functions	2505
3.9.4	Exponentially-weighted window functions	2519
3.9.5	Window indexer	2522
3.10	GroupBy	2525
3.10.1	Indexing, iteration	2525
3.10.2	Function application	2530
3.10.3	Computations / descriptive stats	2542
3.11	Resampling	2597
3.11.1	Indexing, iteration	2597
3.11.2	Function application	2600
3.11.3	Upsampling	2605
3.11.4	Computations / descriptive stats	2617
3.12	Style	2623
3.12.1	Styler constructor	2623
3.12.2	Styler properties	2665

3.12.3	Style application	2666
3.12.4	Builtin styles	2667
3.12.5	Style export and import	2667
3.13	Plotting	2667
3.13.1	pandas.plotting.andrews_curves	2668
3.13.2	pandas.plotting.autocorrelation_plot	2670
3.13.3	pandas.plotting.bootstrap_plot	2671
3.13.4	pandas.plotting.boxplot	2671
3.13.5	pandas.plotting.deregister_matplotlib_converters	2679
3.13.6	pandas.plotting.lag_plot	2679
3.13.7	pandas.plotting.parallel_coordinates	2682
3.13.8	pandas.plotting.plot_params	2682
3.13.9	pandas.plotting.radviz	2684
3.13.10	pandas.plotting.register_matplotlib_converters	2685
3.13.11	pandas.plotting.scatter_matrix	2686
3.13.12	pandas.plotting.table	2688
3.14	General utility functions	2688
3.14.1	Working with options	2688
3.14.2	Testing functions	2707
3.14.3	Exceptions and warnings	2712
3.14.4	Data types related functionality	2717
3.14.5	Bug report function	2744
3.15	Extensions	2745
3.15.1	pandas.api.extensions.register_extension_dtype	2745
3.15.2	pandas.api.extensions.register_dataframe_accessor	2745
3.15.3	pandas.api.extensions.register_series_accessor	2747
3.15.4	pandas.api.extensions.register_index_accessor	2748
3.15.5	pandas.api.extensions.ExtensionDtype	2749
3.15.6	pandas.api.extensions.ExtensionArray	2753
3.15.7	pandas.arrays.PandasArray	2766
3.15.8	pandas.api.indexers.check_array_indexer	2767
4	Development	2769
4.1	Contributing to pandas	2769
4.1.1	Where to start	2770
4.1.2	Bug reports and enhancement requests	2770
4.1.3	Working with the code	2771
4.1.4	Contributing your changes to pandas	2772
4.1.5	Tips for a successful pull request	2775
4.2	Creating a development environment	2775
4.2.1	Creating an environment using Docker	2775
4.2.2	Creating an environment without Docker	2776
4.3	Contributing to the documentation	2779
4.3.1	About the pandas documentation	2780
4.3.2	Updating a pandas docstring	2797
4.3.3	How to build the pandas documentation	2797
4.3.4	Previewing changes	2798
4.4	Contributing to the code base	2798
4.4.1	Code standards	2799
4.4.2	Pre-commit	2799
4.4.3	Optional dependencies	2800
4.4.4	Type hints	2804
4.4.5	Testing with continuous integration	2806
4.4.6	Test-driven development/code writing	2807

4.4.7	Running the test suite	2811
4.4.8	Running the performance test suite	2812
4.4.9	Documenting your code	2813
4.5	pandas code style guide	2813
4.5.1	Patterns	2814
4.5.2	Testing	2814
4.5.3	Miscellaneous	2814

Python Module Index	3703

Date: Feb 12, 2022 **Version:** 1.4.1

Download documentation: [PDF Version](#) | [Zipped HTML](#)

Previous versions: Documentation of previous pandas versions is available at [pandas.pydata.org](#).

Useful links: [Binary Installers](#) | [Source Repository](#) | [Issues & Ideas](#) | [Q&A Support](#) | [Mailing List](#)

pandas is an open source, BSD-licensed library providing high-performance, easy-to-use data structures and data analysis tools for the [Python](#) programming language.

Getting started

New to *pandas*? Check out the getting started guides. They contain an introduction to *pandas*' main concepts and links to additional tutorials.

[To the getting started guides](#)

User guide

The user guide provides in-depth information on the key concepts of pandas with useful background information and explanation.

[To the user guide](#)

API reference

The reference guide contains a detailed description of the pandas API. The reference describes how the methods work and which parameters can be used. It assumes that you have an understanding of the key concepts.

[To the reference guide](#)

Developer guide

Saw a typo in the documentation? Want to improve existing functionalities? The contributing guidelines will guide you through the process of improving pandas.

**CHAPTER
ONE**

GETTING STARTED

1.1 Installation

Working with conda?

pandas is part of the [Anaconda](#) distribution and can be installed with Anaconda or Miniconda:

```
conda install pandas
```

Prefer pip?

pandas can be installed via pip from [PyPI](#).

```
pip install pandas
```

In-depth instructions?

Installing a specific version? Installing from source? Check the advanced installation page.

[Learn more](#)

1.2 Intro to pandas

Straight to tutorial...

When working with tabular data, such as data stored in spreadsheets or databases, pandas is the right tool for you. pandas will help you to explore, clean, and process your data. In pandas, a data table is called a [DataFrame](#).

To introduction tutorial

To user guide

Straight to tutorial...

pandas supports the integration with many file formats or data sources out of the box (csv, excel, sql, json, parquet,...). Importing data from each of these data sources is provided by function with the prefix `read_*`. Similarly, the `to_*` methods are used to store data.

To introduction tutorial

To user guide

Straight to tutorial...

Selecting or filtering specific rows and/or columns? Filtering the data on a condition? Methods for slicing, selecting, and extracting the data you need are available in pandas.

[To introduction tutorial](#)

[To user guide](#)

[Straight to tutorial...](#)

pandas provides plotting your data out of the box, using the power of Matplotlib. You can pick the plot type (scatter, bar, boxplot,...) corresponding to your data.

[To introduction tutorial](#)

[To user guide](#)

[Straight to tutorial...](#)

There is no need to loop over all rows of your data table to do calculations. Data manipulations on a column work elementwise. Adding a column to a `DataFrame` based on existing data in other columns is straightforward.

[To introduction tutorial](#)

[To user guide](#)

[Straight to tutorial...](#)

Basic statistics (mean, median, min, max, counts...) are easily calculable. These or custom aggregations can be applied on the entire data set, a sliding window of the data, or grouped by categories. The latter is also known as the split-apply-combine approach.

[To introduction tutorial](#)

[To user guide](#)

[Straight to tutorial...](#)

Change the structure of your data table in multiple ways. You can `melt()` your data table from wide to long/tidy form or `pivot()` from long to wide format. With aggregations built-in, a pivot table is created with a single command.

[To introduction tutorial](#)

[To user guide](#)

[Straight to tutorial...](#)

Multiple tables can be concatenated both column wise and row wise as database-like join/merge operations are provided to combine multiple tables of data.

[To introduction tutorial](#)

[To user guide](#)

[Straight to tutorial...](#)

pandas has great support for time series and has an extensive set of tools for working with dates, times, and time-indexed data.

[To introduction tutorial](#)

[To user guide](#)

[Straight to tutorial...](#)

Data sets do not only contain numerical data. pandas provides a wide range of functions to clean textual data and extract useful information from it.

[To introduction tutorial](#)

[To user guide](#)

1.3 Coming from...

Are you familiar with other software for manipulating tablular data? Learn the pandas-equivalent operations compared to software you already know:

The R programming language provides the `data.frame` data structure and multiple packages, such as `tidyverse` use and extend `data.frame` for convenient data handling functionalities similar to pandas.

[Learn more](#)

Already familiar to `SELECT`, `GROUP BY`, `JOIN`, etc.? Most of these SQL manipulations do have equivalents in pandas.

[Learn more](#)

The `data set` included in the STATA statistical software suite corresponds to the pandas `DataFrame`. Many of the operations known from STATA have an equivalent in pandas.

[Learn more](#)

Users of Excel or other spreadsheet programs will find that many of the concepts are transferrable to pandas.

[Learn more](#)

The SAS statistical software suite also provides the `data set` corresponding to the pandas `DataFrame`. Also SAS vectorized operations, filtering, string processing operations, and more have similar functions in pandas.

[Learn more](#)

1.4 Tutorials

For a quick overview of pandas functionality, see [10 Minutes to pandas](#).

You can also reference the pandas [cheat sheet](#) for a succinct guide for manipulating data with pandas.

The community produces a wide variety of tutorials available online. Some of the material is enlisted in the community contributed [Community tutorials](#).

1.4.1 Installation

The easiest way to install pandas is to install it as part of the [Anaconda](#) distribution, a cross platform distribution for data analysis and scientific computing. This is the recommended installation method for most users.

Instructions for installing from source, [PyPI](#), [ActivePython](#), various Linux distributions, or a [development version](#) are also provided.

Python version support

Officially Python 3.8, 3.9 and 3.10.

Installing pandas

Installing with Anaconda

Installing pandas and the rest of the [NumPy](#) and [SciPy](#) stack can be a little difficult for inexperienced users.

The simplest way to install not only pandas, but Python and the most popular packages that make up the [SciPy](#) stack ([IPython](#), [NumPy](#), [Matplotlib](#), ...) is with [Anaconda](#), a cross-platform (Linux, macOS, Windows) Python distribution for data analytics and scientific computing.

After running the installer, the user will have access to pandas and the rest of the [SciPy](#) stack without needing to install anything else, and without needing to wait for any software to be compiled.

Installation instructions for [Anaconda](#) can be found [here](#).

A full list of the packages available as part of the [Anaconda](#) distribution can be found [here](#).

Another advantage to installing Anaconda is that you don't need admin rights to install it. Anaconda can install in the user's home directory, which makes it trivial to delete Anaconda if you decide (just delete that folder).

Installing with Miniconda

The previous section outlined how to get pandas installed as part of the [Anaconda](#) distribution. However this approach means you will install well over one hundred packages and involves downloading the installer which is a few hundred megabytes in size.

If you want to have more control on which packages, or have a limited internet bandwidth, then installing pandas with [Miniconda](#) may be a better solution.

[Conda](#) is the package manager that the [Anaconda](#) distribution is built upon. It is a package manager that is both cross-platform and language agnostic (it can play a similar role to a pip and virtualenv combination).

[Miniconda](#) allows you to create a minimal self contained Python installation, and then use the [Conda](#) command to install additional packages.

First you will need [Conda](#) to be installed and downloading and running the [Miniconda](#) will do this for you. The installer can be found [here](#)

The next step is to create a new conda environment. A conda environment is like a virtualenv that allows you to specify a specific version of Python and set of libraries. Run the following commands from a terminal window:

```
conda create -n name_of_my_env python
```

This will create a minimal environment with only Python installed in it. To put your self inside this environment run:

```
source activate name_of_my_env
```

On Windows the command is:

```
activate name_of_my_env
```

The final step required is to install pandas. This can be done with the following command:

```
conda install pandas
```

To install a specific pandas version:

```
conda install pandas=0.20.3
```

To install other packages, IPython for example:

```
conda install ipython
```

To install the full [Anaconda](#) distribution:

```
conda install anaconda
```

If you need packages that are available to pip but not conda, then install pip, and then use pip to install those packages:

```
conda install pip  
pip install django
```

Installing from PyPI

pandas can be installed via pip from [PyPI](#).

Note: You must have `pip>=19.3` to install from PyPI.

```
pip install pandas
```

Installing with ActivePython

Installation instructions for [ActivePython](#) can be found [here](#). Versions 2.7, 3.5 and 3.6 include pandas.

Installing using your Linux distribution's package manager.

The commands in this table will install pandas for Python 3 from your distribution.

Distribution	Status	Download / Repository Link	Install method
Debian	stable	official Debian repository	<code>sudo apt-get install python3-pandas</code>
Debian & Ubuntu	unstable (latest packages)	NeuroDebian	<code>sudo apt-get install python3-pandas</code>
Ubuntu	stable	official Ubuntu repository	<code>sudo apt-get install python3-pandas</code>
OpenSuse	stable	OpenSuse Repository	<code>zypper in python3-pandas</code>
Fedora	stable	official Fedora repository	<code>dnf install python3-pandas</code>
Centos/RHEL	stable	EPEL repository	<code>yum install python3-pandas</code>

However, the packages in the linux package managers are often a few versions behind, so to get the newest version of pandas, it's recommended to install using the pip or conda methods described above.

Handling ImportErrors

If you encounter an ImportError, it usually means that Python couldn't find pandas in the list of available libraries. Python internally has a list of directories it searches through, to find packages. You can obtain these directories with:

```
import sys  
sys.path
```

One way you could be encountering this error is if you have multiple Python installations on your system and you don't have pandas installed in the Python installation you're currently using. In Linux/Mac you can run `which python` on your terminal and it will tell you which Python installation you're using. If it's something like "/usr/bin/python", you're using the Python from the system, which is not recommended.

It is highly recommended to use conda, for quick installation and for package and dependency updates. You can find simple installation instructions for pandas in this document: [installation instructions](#) </getting_started.html>.

Installing from source

See the [contributing guide](#) for complete instructions on building from the git source tree. Further, see [creating a development environment](#) if you wish to create a pandas development environment.

Running the test suite

pandas is equipped with an exhaustive set of unit tests, covering about 97% of the code base as of this writing. To run it on your machine to verify that everything is working (and that you have all of the dependencies, soft and hard, installed), make sure you have `pytest >= 6.0` and `Hypothesis >= 3.58`, then run:

```
>>> pd.test()  
running: pytest --skip-slow --skip-network C:\Users\TP\Anaconda3\envs\py36\lib\site-packages\pandas
```

(continues on next page)

(continued from previous page)

Dependencies

Package	Minimum supported version
NumPy	1.18.5
python-dateutil	2.8.1
pytz	2020.1

Recommended dependencies

- `numexpr`: for accelerating certain numerical operations. `numexpr` uses multiple cores as well as smart chunking and caching to achieve large speedups. If installed, must be Version 2.7.1 or higher.
 - `bottleneck`: for accelerating certain types of `nan` evaluations. `bottleneck` uses specialized cython routines to achieve large speedups. If installed, must be Version 1.3.1 or higher.

Note: You are highly encouraged to install these libraries, as they provide speed improvements, especially when working with large data sets.

Optional dependencies

pandas has many optional dependencies that are only used for specific methods. For example, `pandas.read_hdf()` requires the pytables package, while `DataFrame.to_markdown()` requires the tabulate package. If the optional dependency is not installed, pandas will raise an `ImportError` when the method requiring that dependency is called.

Visualization

Dependency	Minimum Version	Notes
matplotlib	3.3.2	Plotting library
Jinja2	2.11	Conditional formatting with DataFrame.style
tabulate	0.8.7	Printing in Markdown-friendly format (see tabulate)

Computation

Dependency	Minimum Version	Notes
SciPy	1.14.1	Miscellaneous statistical functions
numba	0.50.1	Alternative execution engine for rolling operations (see Enhancing Performance)
xarray	0.15.1	pandas-like API for N-dimensional data

Excel files

Dependency	Minimum Version	Notes
xlrd	2.0.1	Reading Excel
xlwt	1.3.0	Writing Excel
xlsxwriter	1.2.2	Writing Excel
openpyxl	3.0.3	Reading / writing for xlsx files
pyxlsb	1.0.6	Reading for xlsb files

HTML

Dependency	Minimum Version	Notes
BeautifulSoup4	4.8.2	HTML parser for read_html
html5lib	1.1	HTML parser for read_html
lxml	4.5.0	HTML parser for read_html

One of the following combinations of libraries is needed to use the top-level `read_html()` function:

- BeautifulSoup4 and html5lib
- BeautifulSoup4 and lxml
- BeautifulSoup4 and html5lib and lxml
- Only lxml, although see [HTML Table Parsing](#) for reasons as to why you should probably **not** take this approach.

Warning:

- if you install BeautifulSoup4 you must install either lxml or html5lib or both. `read_html()` will **not** work with *only* BeautifulSoup4 installed.
- You are highly encouraged to read [HTML Table Parsing gotchas](#). It explains issues surrounding the installation and usage of the above three libraries.

XML

Dependency	Minimum Version	Notes
lxml	4.5.0	XML parser for read_xml and tree builder for to_xml

SQL databases

Dependency	Minimum Version	Notes
SQLAlchemy	1.4.0	SQL support for databases other than sqlite
psycopg2	2.8.4	PostgreSQL engine for sqlalchemy
pymysql	0.10.1	MySQL engine for sqlalchemy

Other data sources

Dependency	Minimum Version	Notes
PyTables	3.6.1	HDF5-based reading / writing
blosc	1.20.1	Compression for HDF5
zlib		Compression for HDF5
fastparquet	0.4.0	Parquet reading / writing
pyarrow	1.0.1	Parquet, ORC, and feather reading / writing
pyreadstat	1.1.0	SPSS files (.sav) reading

Warning:

- If you want to use `read_orc()`, it is highly recommended to install pyarrow using conda. The following is a summary of the environment in which `read_orc()` can work.

System	Conda	PyPI
Linux	Successful	Failed(pyarrow==3.0 Successful)
macOS	Successful	Failed
Windows	Failed	Failed

Access data in the cloud

Dependency	Minimum Version	Notes
fsspec	0.7.4	Handling files aside from simple local and HTTP
gcsfs	0.6.0	Google Cloud Storage access
pandas-gbq	0.14.0	Google Big Query access
s3fs	0.4.0	Amazon S3 access

Clipboard

Dependency	Minimum Version	Notes
PyQt4/PyQt5		Clipboard I/O
qtpy		Clipboard I/O
xclip		Clipboard I/O on linux
xsel		Clipboard I/O on linux

Compression

Dependency	Minimum Version	Notes
Zstandard		Zstandard compression

1.4.2 Package overview

pandas is a [Python](#) package providing fast, flexible, and expressive data structures designed to make working with “relational” or “labeled” data both easy and intuitive. It aims to be the fundamental high-level building block for doing practical, **real-world** data analysis in Python. Additionally, it has the broader goal of becoming **the most powerful and flexible open source data analysis/manipulation tool available in any language**. It is already well on its way toward this goal.

pandas is well suited for many different kinds of data:

- Tabular data with heterogeneously-typed columns, as in an SQL table or Excel spreadsheet
- Ordered and unordered (not necessarily fixed-frequency) time series data.
- Arbitrary matrix data (homogeneously typed or heterogeneous) with row and column labels
- Any other form of observational / statistical data sets. The data need not be labeled at all to be placed into a pandas data structure

The two primary data structures of pandas, [*Series*](#) (1-dimensional) and [*DataFrame*](#) (2-dimensional), handle the vast majority of typical use cases in finance, statistics, social science, and many areas of engineering. For R users, [*DataFrame*](#) provides everything that R’s `data.frame` provides and much more. pandas is built on top of [*NumPy*](#) and is intended to integrate well within a scientific computing environment with many other 3rd party libraries.

Here are just a few of the things that pandas does well:

- Easy handling of **missing data** (represented as NaN) in floating point as well as non-floating point data
- Size mutability: columns can be **inserted and deleted** from DataFrame and higher dimensional objects
- Automatic and explicit **data alignment**: objects can be explicitly aligned to a set of labels, or the user can simply ignore the labels and let Series, DataFrame, etc. automatically align the data for you in computations
- Powerful, flexible **group by** functionality to perform split-apply-combine operations on data sets, for both aggregating and transforming data
- Make it **easy to convert** ragged, differently-indexed data in other Python and NumPy data structures into DataFrame objects
- Intelligent label-based **slicing, fancy indexing**, and **subsetting** of large data sets
- Intuitive **merging** and **joining** data sets
- Flexible **reshaping** and pivoting of data sets

- **Hierarchical** labeling of axes (possible to have multiple labels per tick)
- Robust IO tools for loading data from **flat files** (CSV and delimited), Excel files, databases, and saving / loading data from the ultrafast **HDF5 format**
- **Time series**-specific functionality: date range generation and frequency conversion, moving window statistics, date shifting, and lagging.

Many of these principles are here to address the shortcomings frequently experienced using other languages / scientific research environments. For data scientists, working with data is typically divided into multiple stages: munging and cleaning data, analyzing / modeling it, then organizing the results of the analysis into a form suitable for plotting or tabular display. pandas is the ideal tool for all of these tasks.

Some other notes

- pandas is **fast**. Many of the low-level algorithmic bits have been extensively tweaked in [Cython](#) code. However, as with anything else generalization usually sacrifices performance. So if you focus on one feature for your application you may be able to create a faster specialized tool.
- pandas is a dependency of [statsmodels](#), making it an important part of the statistical computing ecosystem in Python.
- pandas has been used extensively in production in financial applications.

Data structures

Dimensions	Name	Description
1	Series	1D labeled homogeneously-typed array
2	DataFrame	General 2D labeled, size-mutable tabular structure with potentially heterogeneously-typed column

Why more than one data structure?

The best way to think about the pandas data structures is as flexible containers for lower dimensional data. For example, DataFrame is a container for Series, and Series is a container for scalars. We would like to be able to insert and remove objects from these containers in a dictionary-like fashion.

Also, we would like sensible default behaviors for the common API functions which take into account the typical orientation of time series and cross-sectional data sets. When using the N-dimensional array (ndarrays) to store 2- and 3-dimensional data, a burden is placed on the user to consider the orientation of the data set when writing functions; axes are considered more or less equivalent (except when C- or Fortran-contiguity matters for performance). In pandas, the axes are intended to lend more semantic meaning to the data; i.e., for a particular data set, there is likely to be a “right” way to orient the data. The goal, then, is to reduce the amount of mental effort required to code up data transformations in downstream functions.

For example, with tabular data (DataFrame) it is more semantically helpful to think of the **index** (the rows) and the **columns** rather than axis 0 and axis 1. Iterating through the columns of the DataFrame thus results in more readable code:

```
for col in df.columns:
    series = df[col]
    # do something with series
```

Mutability and copying of data

All pandas data structures are value-mutable (the values they contain can be altered) but not always size-mutable. The length of a Series cannot be changed, but, for example, columns can be inserted into a DataFrame. However, the vast majority of methods produce new objects and leave the input data untouched. In general we like to **favor immutability** where sensible.

Getting support

The first stop for pandas issues and ideas is the [Github Issue Tracker](#). If you have a general question, pandas community experts can answer through [Stack Overflow](#).

Community

pandas is actively supported today by a community of like-minded individuals around the world who contribute their valuable time and energy to help make open source pandas possible. Thanks to [all of our contributors](#).

If you're interested in contributing, please visit the [contributing guide](#).

pandas is a [NumFOCUS](#) sponsored project. This will help ensure the success of the development of pandas as a world-class open-source project and makes it possible to [donate](#) to the project.

Project governance

The governance process that pandas project has used informally since its inception in 2008 is formalized in [Project Governance documents](#). The documents clarify how decisions are made and how the various elements of our community interact, including the relationship between open source collaborative development and work that may be funded by for-profit or non-profit entities.

Wes McKinney is the Benevolent Dictator for Life (BDFL).

Development team

The list of the Core Team members and more detailed information can be found on the [people's page](#) of the governance repo.

Institutional partners

The information about current institutional partners can be found on [pandas website page](#).

1.4.3 Getting started tutorials

What kind of data does pandas handle?

I want to start using pandas

In [1]: `import pandas as pd`

To load the pandas package and start working with it, import the package. The community agreed alias for pandas is `pd`, so loading pandas as `pd` is assumed standard practice for all of the pandas documentation.

pandas data table representation

I want to store passenger data of the Titanic. For a number of passengers, I know the name (characters), age (integers) and sex (male/female) data.

In [2]: `df = pd.DataFrame(`
`..... {`
`..... "Name": [`
`..... "Braund, Mr. Owen Harris",`
`..... "Allen, Mr. William Henry",`
`..... "Bonnell, Miss. Elizabeth",`
`.....],`

(continues on next page)

(continued from previous page)

```

...:     "Age": [22, 35, 58],
...:     "Sex": ["male", "male", "female"],
...:   }
...: )
...:

In [3]: df
Out[3]:
      Name  Age    Sex
0  Braund, Mr. Owen Harris    22  male
1  Allen, Mr. William Henry    35  male
2  Bonnell, Miss. Elizabeth    58 female

```

To manually store data in a table, create a `DataFrame`. When using a Python dictionary of lists, the dictionary keys will be used as column headers and the values in each list as columns of the `DataFrame`.

A `DataFrame` is a 2-dimensional data structure that can store data of different types (including characters, integers, floating point values, categorical data and more) in columns. It is similar to a spreadsheet, a SQL table or the `data.frame` in R.

- The table has 3 columns, each of them with a column label. The column labels are respectively `Name`, `Age` and `Sex`.
- The column `Name` consists of textual data with each value a string, the column `Age` are numbers and the column `Sex` is textual data.

In spreadsheet software, the table representation of our data would look very similar:

	B	C	D	E	F
1	Name	Age	Sex		
2	Braund, Mr. Owen Harris	22	male		
3	Allen, Mr. William Henry	35	male		
4	Bonnell, Miss. Elizabeth	58	female		
5					
6					
7					
8					

Each column in a DataFrame is a Series

I'm just interested in working with the data in the column `Age`

```
In [4]: df["Age"]
Out[4]:
0    22
1    35
2    58
Name: Age, dtype: int64
```

When selecting a single column of a pandas `DataFrame`, the result is a pandas `Series`. To select the column, use the column label in between square brackets `[]`.

Note: If you are familiar to Python `dictionaries`, the selection of a single column is very similar to selection of dictionary values based on the key.

You can create a `Series` from scratch as well:

```
In [5]: ages = pd.Series([22, 35, 58], name="Age")
In [6]: ages
Out[6]:
0    22
1    35
2    58
Name: Age, dtype: int64
```

A pandas `Series` has no column labels, as it is just a single column of a `DataFrame`. A `Series` does have row labels.

Do something with a DataFrame or Series

I want to know the maximum `Age` of the passengers

We can do this on the `DataFrame` by selecting the `Age` column and applying `max()`:

```
In [7]: df["Age"].max()
Out[7]: 58
```

Or to the `Series`:

```
In [8]: ages.max()
Out[8]: 58
```

As illustrated by the `max()` method, you can *do* things with a `DataFrame` or `Series`. pandas provides a lot of functionalities, each of them a *method* you can apply to a `DataFrame` or `Series`. As methods are functions, do not forget to use parentheses `()`.

I'm interested in some basic statistics of the numerical data of my data table

```
In [9]: df.describe()
```

```
Out[9]:
```

```
Age
count    3.000000
mean    38.333333
std     18.230012
min    22.000000
25%   28.500000
50%   35.000000
75%   46.500000
max    58.000000
```

The `describe()` method provides a quick overview of the numerical data in a DataFrame. As the Name and Sex columns are textual data, these are by default not taken into account by the `describe()` method.

Many pandas operations return a DataFrame or a Series. The `describe()` method is an example of a pandas operation returning a pandas Series or a pandas DataFrame.

Check more options on `describe` in the user guide section about *aggregations with describe*

Note: This is just a starting point. Similar to spreadsheet software, pandas represents data as a table with columns and rows. Apart from the representation, also the data manipulations and calculations you would do in spreadsheet software are supported by pandas. Continue reading the next tutorials to get started!

- Import the package, aka `import pandas as pd`
- A table of data is stored as a pandas DataFrame
- Each column in a DataFrame is a Series
- You can do things by applying a method to a DataFrame or Series

A more extended explanation to DataFrame and Series is provided in the [introduction to data structures](#).

```
In [1]: import pandas as pd
```

This tutorial uses the Titanic data set, stored as CSV. The data consists of the following data columns:

- PassengerId: Id of every passenger.
- Survived: This feature have value 0 and 1. 0 for not survived and 1 for survived.
- Pclass: There are 3 classes: Class 1, Class 2 and Class 3.
- Name: Name of passenger.
- Sex: Gender of passenger.
- Age: Age of passenger.
- SibSp: Indication that passenger have siblings and spouse.
- Parch: Whether a passenger is alone or have family.
- Ticket: Ticket number of passenger.
- Fare: Indicating the fare.
- Cabin: The cabin of passenger.
- Embarked: The embarked category.

How do I read and write tabular data?

I want to analyze the Titanic passenger data, available as a CSV file.

```
In [2]: titanic = pd.read_csv("data/titanic.csv")
```

pandas provides the `read_csv()` function to read data stored as a csv file into a pandas DataFrame. pandas supports many different file formats or data sources out of the box (csv, excel, sql, json, parquet, ...), each of them with the prefix `read_*`.

Make sure to always have a check on the data after reading in the data. When displaying a DataFrame, the first and last 5 rows will be shown by default:

```
In [3]: titanic
```

```
Out[3]:
```

	PassengerId	Survived	Pclass	Ticket	Fare	Cabin	Embarked	Name	...
0		1	0	3				Braund, Mr. Owen Harris	..
1	A/5 21171	2	1		7.2500	NaN	S	Cumings, Mrs. John Bradley (Florence Briggs Th... Heikkinen, Miss. Laina	..
2	PC 17599	3	1		71.2833	C85	C		..
3	STON/O2. 3101282	4	1		7.9250	NaN	S	Futrelle, Mrs. Jacques Heath (Lily May Peel)	..
4		5	0		53.1000	C123	S	Allen, Mr. William Henry	..
5		373450			8.0500	NaN	S		..
..	
886		887	0		2			Montvila, Rev. Juozas	..
887		211536		13.0000		NaN	S	Graham, Miss. Margaret Edith	..
888		888	1		1			Johnston, Miss. Catherine Helen "Carrie"	..
889		112053		30.0000		B42	S		..
890		889	0		23.4500	NaN	S	Behr, Mr. Karl Howell	..
891		W./C. 6607	1		1			Dooley, Mr. Patrick	..
892		890			111369	30.0000	C148		..
893		891	0		370376	8.0500	C		..
894		370376			7.7500	NaN	Q		..
[891 rows x 12 columns]									

I want to see the first 8 rows of a pandas DataFrame.

```
In [4]: titanic.head(8)
```

```
Out[4]:
```

	PassengerId	Survived	Pclass	Ticket	Fare	Cabin	Embarked	Name	...
0	1	0	3					Braund, Mr. Owen Harris	...
1	A/5 21171	2	1		7.2500	NaN	S	Cumings, Mrs. John Bradley (Florence Briggs Th... Heikkinen, Miss. Laina	...
2	PC 17599	3	1		71.2833	C85	C		...
3	STON/O2. 3101282	4	1		7.9250	NaN	S	(continues on next page)	...

(continued from previous page)

3	4	1	1	Futrelle, Mrs. Jacques Heath (Lily May Peel)
↪	113803	53.1000	C123	S	
4	5	0	3		Allen, Mr. William Henry
↪	373450	8.0500	NaN	S	
5	6	0	3		Moran, Mr. James
↪	330877	8.4583	NaN	Q	
6	7	0	1		McCarthy, Mr. Timothy J
↪	17463	51.8625	E46	S	
7	8	0	3		Palsson, Master. Gosta Leonard
↪	349909	21.0750	NaN	S	

[8 rows x 12 columns]

To see the first N rows of a DataFrame, use the `head()` method with the required number of rows (in this case 8) as argument.

Note: Interested in the last N rows instead? pandas also provides a `tail()` method. For example, `titanic.tail(10)` will return the last 10 rows of the DataFrame.

A check on how pandas interpreted each of the column data types can be done by requesting the pandas `dtypes` attribute:

```
In [5]: titanic.dtypes
```

```
Out[5]:
```

PassengerId	int64
Survived	int64
Pclass	int64
Name	object
Sex	object
Age	float64
SibSp	int64
Parch	int64
Ticket	object
Fare	float64
Cabin	object
Embarked	object
dtype:	object

For each of the columns, the used data type is enlisted. The data types in this DataFrame are integers (`int64`), floats (`float64`) and strings (`object`).

Note: When asking for the `dtypes`, no brackets are used! `dtypes` is an attribute of a DataFrame and Series. Attributes of DataFrame or Series do not need brackets. Attributes represent a characteristic of a DataFrame/Series, whereas a method (which requires brackets) *do* something with the DataFrame/Series as introduced in the [first tutorial](#).

My colleague requested the Titanic data as a spreadsheet.

```
In [6]: titanic.to_excel("titanic.xlsx", sheet_name="passengers", index=False)
```

Whereas `read_*` functions are used to read data to pandas, the `to_*` methods are used to store data. The `to_excel()`

method stores the data as an excel file. In the example here, the `sheet_name` is named `passengers` instead of the default `Sheet1`. By setting `index=False` the row index labels are not saved in the spreadsheet.

The equivalent read function `read_excel()` will reload the data to a `DataFrame`:

```
In [7]: titanic = pd.read_excel("titanic.xlsx", sheet_name="passengers")
```

```
In [8]: titanic.head()
```

```
Out[8]:
```

	PassengerId	Survived	Pclass	Ticket	Fare	Cabin	Embarked	Name
0		1	3		0		3	Braund, Mr. Owen Harris
1	A/5 21171	2	1	1	7.2500	Cumings, Mrs. John Bradley (Florence Briggs Th... C	S	
2	PC 17599	3	1	PC 17599	71.2833	C85		Heikkinen, Miss. Laina
3	STON/O2. 3101282	4	1	3101282	7.9250		S	Futrelle, Mrs. Jacques Heath (Lily May Peel)
4		5	0	113803	53.1000	C123	S	Allen, Mr. William Henry
5				373450	8.0500		Nan	

[5 rows x 12 columns]

I'm interested in a technical summary of a `DataFrame`

```
In [9]: titanic.info()
```

```
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 891 entries, 0 to 890
Data columns (total 12 columns):
 #   Column      Non-Null Count  Dtype  
 --- 
 0   PassengerId 891 non-null    int64  
 1   Survived     891 non-null    int64  
 2   Pclass       891 non-null    int64  
 3   Name         891 non-null    object 
 4   Sex          891 non-null    object 
 5   Age          714 non-null    float64 
 6   SibSp        891 non-null    int64  
 7   Parch        891 non-null    int64  
 8   Ticket       891 non-null    object 
 9   Fare          891 non-null    float64 
 10  Cabin        204 non-null    object 
 11  Embarked     889 non-null    object 
dtypes: float64(2), int64(5), object(5)
memory usage: 83.7+ KB
```

The method `info()` provides technical information about a `DataFrame`, so let's explain the output in more detail:

- It is indeed a `DataFrame`.
- There are 891 entries, i.e. 891 rows.
- Each row has a row label (aka the `index`) with values ranging from 0 to 890.
- The table has 12 columns. Most columns have a value for each of the rows (all 891 values are `non-null`). Some columns do have missing values and less than 891 `non-null` values.

- The columns Name, Sex, Cabin and Embarked consists of textual data (strings, aka object). The other columns are numerical data with some of them whole numbers (aka integer) and others are real numbers (aka float).
- The kind of data (characters, integers,...) in the different columns are summarized by listing the dtypes.
- The approximate amount of RAM used to hold the DataFrame is provided as well.
- Getting data in to pandas from many different file formats or data sources is supported by read_* functions.
- Exporting data out of pandas is provided by different to_*methods.
- The head/tail/info methods and the dtypes attribute are convenient for a first check.

For a complete overview of the input and output possibilities from and to pandas, see the user guide section about *reader and writer functions*.

```
In [1]: import pandas as pd
```

This tutorial uses the Titanic data set, stored as CSV. The data consists of the following data columns:

- PassengerId: Id of every passenger.
- Survived: This feature have value 0 and 1. 0 for not survived and 1 for survived.
- Pclass: There are 3 classes: Class 1, Class 2 and Class 3.
- Name: Name of passenger.
- Sex: Gender of passenger.
- Age: Age of passenger.
- SibSp: Indication that passenger have siblings and spouse.
- Parch: Whether a passenger is alone or have family.
- Ticket: Ticket number of passenger.
- Fare: Indicating the fare.
- Cabin: The cabin of passenger.
- Embarked: The embarked category.

```
In [2]: titanic = pd.read_csv("data/titanic.csv")
```

```
In [3]: titanic.head()
```

```
Out[3]:
```

	PassengerId	Survived	Pclass	Ticket	Fare	Cabin	Embarked	Name	...
0		1	3		0	3		Braund, Mr. Owen Harris	...
1	A/5 21171		1	313330	7.2500	NaN	S	Cumings, Mrs. John Bradley (Florence Briggs Th...	...
2	PC 17599		1	34101	71.2833	C85	C	Heikkinen, Miss. Laina	...
3	STON/O2. 3101282		1	341308	7.9250	NaN	S	Futrelle, Mrs. Jacques Heath (Lily May Peel)	...
4	313450		3	341308	53.1000	C123	S	Allen, Mr. William Henry	...

[5 rows x 12 columns]

How do I select a subset of a DataFrame?

How do I select specific columns from a DataFrame?

I'm interested in the age of the Titanic passengers.

```
In [4]: ages = titanic["Age"]
```

```
In [5]: ages.head()
```

```
Out[5]:
```

```
0    22.0  
1    38.0  
2    26.0  
3    35.0  
4    35.0  
Name: Age, dtype: float64
```

To select a single column, use square brackets [] with the column name of the column of interest.

Each column in a `DataFrame` is a `Series`. As a single column is selected, the returned object is a pandas `Series`. We can verify this by checking the type of the output:

```
In [6]: type(titanic["Age"])
```

```
Out[6]: pandas.core.series.Series
```

And have a look at the shape of the output:

```
In [7]: titanic["Age"].shape
```

```
Out[7]: (891,)
```

`DataFrame.shape` is an attribute (remember *tutorial on reading and writing*, do not use parentheses for attributes) of a pandas Series and DataFrame containing the number of rows and columns: (`nrows`, `ncolumns`). A pandas Series is 1-dimensional and only the number of rows is returned.

I'm interested in the age and sex of the Titanic passengers.

```
In [8]: age_sex = titanic[["Age", "Sex"]]
```

```
In [9]: age_sex.head()
```

```
Out[9]:
```

	Age	Sex
0	22.0	male
1	38.0	female
2	26.0	female
3	35.0	female
4	35.0	male

To select multiple columns, use a list of column names within the selection brackets [].

Note: The inner square brackets define a `Python list` with column names, whereas the outer brackets are used to select the data from a pandas `DataFrame` as seen in the previous example.

The returned data type is a pandas DataFrame:

```
In [10]: type(titanic[["Age", "Sex"]])
Out[10]: pandas.core.frame.DataFrame
```

```
In [11]: titanic[["Age", "Sex"]].shape
Out[11]: (891, 2)
```

The selection returned a DataFrame with 891 rows and 2 columns. Remember, a DataFrame is 2-dimensional with both a row and column dimension.

For basic information on indexing, see the user guide section on [indexing and selecting data](#).

How do I filter specific rows from a DataFrame?

I'm interested in the passengers older than 35 years.

```
In [12]: above_35 = titanic[titanic["Age"] > 35]
```

```
In [13]: above_35.head()
```

```
Out[13]:
   PassengerId  Survived  Pclass          Name
   ↗ Sex ...  Parch     Ticket     Fare Cabin Embarked
1      female    1        1   Cumings, Mrs. John Bradley (Florence Briggs Th...
6      male     0        1           1
11     female   12        1           1
13     male     0        3           1
15     female   16        1           2
   ↗ female ...  0        0           0
[5 rows x 12 columns]
```

To select rows based on a conditional expression, use a condition inside the selection brackets [].

The condition inside the selection brackets `titanic["Age"] > 35` checks for which rows the Age column has a value larger than 35:

```
In [14]: titanic["Age"] > 35
```

```
Out[14]:
```

```
0      False
1      True
2      False
3      False
4      False
...
886     False
887     False
888     False
889     False
```

(continues on next page)

(continued from previous page)

```
890    False
Name: Age, Length: 891, dtype: bool
```

The output of the conditional expression (`>`, but also `==`, `!=`, `<`, `<=`,...) would work) is actually a pandas Series of boolean values (either True or False) with the same number of rows as the original DataFrame. Such a Series of boolean values can be used to filter the DataFrame by putting it in between the selection brackets `[]`. Only rows for which the value is True will be selected.

We know from before that the original Titanic DataFrame consists of 891 rows. Let's have a look at the number of rows which satisfy the condition by checking the shape attribute of the resulting DataFrame `above_35`:

```
In [15]: above_35.shape
Out[15]: (217, 12)
```

I'm interested in the Titanic passengers from cabin class 2 and 3.

```
In [16]: class_23 = titanic[titanic["Pclass"].isin([2, 3])]
```

```
In [17]: class_23.head()
```

```
Out[17]:
   PassengerId  Survived  Pclass
   ↵Parch          Ticket      Fare Cabin Embarked
0           1         0        3      Braund, Mr. Owen Harris   male  22.0      1
   ↵ 0          A/5 21171  7.2500     NaN       S
2           3         1        3      Heikkinen, Miss. Laina  female  26.0      0
   ↵ 0  STON/O2. 3101282  7.9250     NaN       S
4           5         0        3      Allen, Mr. William Henry   male  35.0      0
   ↵ 0          373450  8.0500     NaN       S
5           6         0        3      Moran, Mr. James   male   NaN      0
   ↵ 0          330877  8.4583     NaN       Q
7           8         0        3  Palsson, Master. Gosta Leonard   male   2.0      3
   ↵ 1          349909 21.0750     NaN       S
```

Similar to the conditional expression, the `isin()` conditional function returns a True for each row the values are in the provided list. To filter the rows based on such a function, use the conditional function inside the selection brackets `[]`. In this case, the condition inside the selection brackets `titanic["Pclass"].isin([2, 3])` checks for which rows the Pclass column is either 2 or 3.

The above is equivalent to filtering by rows for which the class is either 2 or 3 and combining the two statements with an `|` (or) operator:

```
In [18]: class_23 = titanic[(titanic["Pclass"] == 2) | (titanic["Pclass"] == 3)]
```

```
In [19]: class_23.head()
```

```
Out[19]:
   PassengerId  Survived  Pclass
   ↵Parch          Ticket      Fare Cabin Embarked
0           1         0        3      Braund, Mr. Owen Harris   male  22.0      1
   ↵ 0          A/5 21171  7.2500     NaN       S
2           3         1        3      Heikkinen, Miss. Laina  female  26.0      0
   ↵ 0  STON/O2. 3101282  7.9250     NaN       S
4           5         0        3      Allen, Mr. William Henry   male  35.0      0
   ↵ 0          373450  8.0500     NaN       S
5           6         0        3      Moran, Mr. James   male   NaN      0
   ↵ 0          330877  8.4583     NaN       Q
```

(continues on next page)

(continued from previous page)

7	8	0	3	Palsson, Master.	Gosta Leonard	male	2.0	3	...
↪	1	349909	21.0750	NaN	S				

Note: When combining multiple conditional statements, each condition must be surrounded by parentheses (). Moreover, you can not use or/and but need to use the or operator | and the and operator &.

See the dedicated section in the user guide about [boolean indexing](#) or about the [isin function](#).

I want to work with passenger data for which the age is known.

```
In [20]: age_no_na = titanic[titanic["Age"].notna()]
```

```
In [21]: age_no_na.head()
```

Out[21]:

	PassengerId	Survived	Pclass	Ticket	Fare	Cabin	Embarked	Name	...
↪	0	1	3					Braund, Mr. Owen Harris	...
↪	1	2	1	A/5 21171	7.2500	NaN	S	Cumings, Mrs. John Bradley (Florence Briggs Th...	...
↪	2	3	1	PC 17599	71.2833	C85	C	Heikkinen, Miss. Laina	...
↪	3	4	1	STON/O2. 3101282	7.9250	NaN	S	Futrelle, Mrs. Jacques Heath (Lily May Peel)	...
↪	4	5	0	113803	53.1000	C123	S	Allen, Mr. William Henry	...
↪				373450	8.0500	NaN	S		

[5 rows x 12 columns]

The `notna()` conditional function returns a True for each row the values are not an Null value. As such, this can be combined with the selection brackets [] to filter the data table.

You might wonder what actually changed, as the first 5 lines are still the same values. One way to verify is to check if the shape has changed:

```
In [22]: age_no_na.shape
```

Out[22]: (714, 12)

For more dedicated functions on missing values, see the user guide section about [handling missing data](#).

How do I select specific rows and columns from a DataFrame?

I'm interested in the names of the passengers older than 35 years.

```
In [23]: adult_names = titanic.loc[titanic["Age"] > 35, "Name"]
```

```
In [24]: adult_names.head()
```

Out[24]:

1 Cummings, Mrs. John Bradley (Florence Briggs Th...

(continues on next page)

(continued from previous page)

```

6          McCarthy, Mr. Timothy J
11         Bonnell, Miss. Elizabeth
13        Andersson, Mr. Anders Johan
15       Hewlett, Mrs. (Mary D Kingcome)
Name: Name, dtype: object

```

In this case, a subset of both rows and columns is made in one go and just using selection brackets [] is not sufficient anymore. The loc/iloc operators are required in front of the selection brackets []. When using loc/iloc, the part before the comma is the rows you want, and the part after the comma is the columns you want to select.

When using the column names, row labels or a condition expression, use the loc operator in front of the selection brackets []. For both the part before and after the comma, you can use a single label, a list of labels, a slice of labels, a conditional expression or a colon. Using a colon specifies you want to select all rows or columns.

I'm interested in rows 10 till 25 and columns 3 to 5.

```
In [25]: titanic.iloc[9:25, 2:5]
```

```
Out[25]:
```

	Pclass	Name	Sex
9	2	Nasser, Mrs. Nicholas (Adele Achem)	female
10	3	Sandstrom, Miss. Marguerite Rut	female
11	1	Bonnell, Miss. Elizabeth	female
12	3	Saunderscock, Mr. William Henry	male
13	3	Andersson, Mr. Anders Johan	male
..
20	2	Fynney, Mr. Joseph J	male
21	2	Beesley, Mr. Lawrence	male
22	3	McGowan, Miss. Anna "Annie"	female
23	1	Sloper, Mr. William Thompson	male
24	3	Palsson, Miss. Torborg Danira	female

[16 rows x 3 columns]

Again, a subset of both rows and columns is made in one go and just using selection brackets [] is not sufficient anymore. When specifically interested in certain rows and/or columns based on their position in the table, use the iloc operator in front of the selection brackets [].

When selecting specific rows and/or columns with loc or iloc, new values can be assigned to the selected data. For example, to assign the name anonymous to the first 3 elements of the third column:

```
In [26]: titanic.iloc[0:3, 3] = "anonymous"
```

```
In [27]: titanic.head()
```

```
Out[27]:
```

	PassengerId	Survived	Pclass	Name	...
	Ticket	Fare	Cabin	Embarked	
0		1	0	3	anonymous
1	A/5 21171	7.2500	Nan	S	...
2	PC 17599	71.2833	C85	C	...
3	STON/O2. 3101282	7.9250	Nan	S	...
4	113803	53.1000	C123	S	...

(continues on next page)

(continued from previous page)

4	5	0	3		Allen, Mr. William Henry	...	
↪	373450	8.0500	NaN	S			↪
[5 rows x 12 columns]							

See the user guide section on [different choices for indexing](#) to get more insight in the usage of loc and iloc.

- When selecting subsets of data, square brackets [] are used.
- Inside these brackets, you can use a single column/row label, a list of column/row labels, a slice of labels, a conditional expression or a colon.
- Select specific rows and/or columns using loc when using the row and column names
- Select specific rows and/or columns using iloc when using the positions in the table
- You can assign new values to a selection based on loc/iloc.

A full overview of indexing is provided in the user guide pages on [indexing and selecting data](#).

In [1]: `import pandas as pd`

In [2]: `import matplotlib.pyplot as plt`

For this tutorial, air quality data about NO_2 is used, made available by [openaq](#) and using the [py-openaq](#) package. The `air_quality_no2.csv` data set provides NO_2 values for the measurement stations *FR04014*, *BETR801* and *London Westminster* in respectively Paris, Antwerp and London.

In [3]: `air_quality = pd.read_csv("data/air_quality_no2.csv", index_col=0, parse_dates=True)`

In [4]: `air_quality.head()`

Out[4]:

	station_antwerp	station_paris	station_london
datetime			
2019-05-07 02:00:00	NaN	NaN	23.0
2019-05-07 03:00:00	50.5	25.0	19.0
2019-05-07 04:00:00	45.0	27.7	19.0
2019-05-07 05:00:00	NaN	50.4	16.0
2019-05-07 06:00:00	NaN	61.9	NaN

Note: The usage of the `index_col` and `parse_dates` parameters of the `read_csv` function to define the first (0th) column as index of the resulting DataFrame and convert the dates in the column to [Timestamp](#) objects, respectively.

How to create plots in pandas?

I want a quick visual check of the data.

```
In [5]: air_quality.plot()  
Out[5]: <AxesSubplot:xlabel='datetime'>
```

With a DataFrame, pandas creates by default one line plot for each of the columns with numeric data.

I want to plot only the columns of the data table with the data from Paris.

```
In [6]: air_quality["station_paris"].plot()  
Out[6]: <AxesSubplot:xlabel='datetime'>
```

To plot a specific column, use the selection method of the [subset data tutorial](#) in combination with the `plot()` method. Hence, the `plot()` method works on both Series and DataFrame.

I want to visually compare the $N0_2$ values measured in London versus Paris.

```
In [7]: air_quality.plot.scatter(x="station_london", y="station_paris", alpha=0.5)
Out[7]: <AxesSubplot:xlabel='station_london', ylabel='station_paris'>
```

Apart from the default `line` plot when using the `plot` function, a number of alternatives are available to plot data. Let's use some standard Python to get an overview of the available plot methods:

```
In [8]: [
    ....:     method_name
    ....:     for method_name in dir(air_quality.plot)
    ....:     if not method_name.startswith("_")
    ....: ]
....:
```

Out[8]:

```
['area',
 'bar',
 'barh',
 'box',
 'density',
 'hexbin',
 'hist',
 'kde',
 'line',
 'pie',
 'scatter']
```

Note: In many development environments as well as IPython and Jupyter Notebook, use the TAB button to get an

overview of the available methods, for example `air_quality.plot.` + TAB.

One of the options is `DataFrame.plot.box()`, which refers to a boxplot. The box method is applicable on the air quality example data:

```
In [9]: air_quality.plot.box()
```

```
Out[9]: <AxesSubplot:>
```

For an introduction to plots other than the default line plot, see the user guide section about [supported plot styles](#).

I want each of the columns in a separate subplot.

```
In [10]: axs = air_quality.plot.area(figsize=(12, 4), subplots=True)
```

Separate subplots for each of the data columns are supported by the `subplots` argument of the plot functions. The builtin options available in each of the pandas plot functions are worth reviewing.

Some more formatting options are explained in the user guide section on [plot formatting](#).

I want to further customize, extend or save the resulting plot.

```
In [11]: fig, axs = plt.subplots(figsize=(12, 4))

In [12]: air_quality.plot.area(ax=axs)
Out[12]: <AxesSubplot:xlabel='datetime'>

In [13]: axs.set_ylabel("NO$_2$ concentration")
Out[13]: Text(0, 0.5, 'NO$_2$ concentration')

In [14]: fig.savefig("no2_concentrations.png")
```

Each of the plot objects created by pandas is a matplotlib object. As Matplotlib provides plenty of options to customize plots, making the link between pandas and Matplotlib explicit enables all the power of matplotlib to the plot. This strategy is applied in the previous example:

```
fig, axs = plt.subplots(figsize=(12, 4))          # Create an empty matplotlib Figure and
# Axes
air_quality.plot.area(ax=axs)                  # Use pandas to put the area plot on the
# prepared Figure/Axes
axs.set_ylabel("NO$_2$ concentration")        # Do any matplotlib customization you
# like
```

(continues on next page)

(continued from previous page)

```
fig.savefig("no2_concentrations.png")           # Save the Figure/Axes using the
→existing matplotlib method.
```

- The `.plot.*` methods are applicable on both Series and DataFrames
- By default, each of the columns is plotted as a different element (line, boxplot,...)
- Any plot created by pandas is a Matplotlib object.

A full overview of plotting in pandas is provided in the *visualization pages*.

```
In [1]: import pandas as pd
```

For this tutorial, air quality data about NO_2 is used, made available by `openaq` and using the `py-openaq` package. The `air_quality_no2.csv` data set provides NO_2 values for the measurement stations *FR04014*, *BETR801* and *London Westminster* in respectively Paris, Antwerp and London.

```
In [2]: air_quality = pd.read_csv("data/air_quality_no2.csv", index_col=0, parse_
→dates=True)
```

```
In [3]: air_quality.head()
```

```
Out[3]:
```

	station_antwerp	station_paris	station_london
datetime			
2019-05-07 02:00:00	NaN	NaN	23.0
2019-05-07 03:00:00	50.5	25.0	19.0
2019-05-07 04:00:00	45.0	27.7	19.0
2019-05-07 05:00:00	NaN	50.4	16.0
2019-05-07 06:00:00	NaN	61.9	NaN

How to create new columns derived from existing columns?

I want to express the NO_2 concentration of the station in London in mg/m³

(If we assume temperature of 25 degrees Celsius and pressure of 1013 hPa, the conversion factor is 1.882)

```
In [4]: air_quality["london_mg_per_cubic"] = air_quality["station_london"] * 1.882
```

```
In [5]: air_quality.head()
```

```
Out[5]:
```

	station_antwerp	station_paris	station_london	london_mg_per_cubic
datetime				
2019-05-07 02:00:00	NaN	NaN	23.0	43.286
2019-05-07 03:00:00	50.5	25.0	19.0	35.758
2019-05-07 04:00:00	45.0	27.7	19.0	35.758
2019-05-07 05:00:00	NaN	50.4	16.0	30.112
2019-05-07 06:00:00	NaN	61.9	NaN	NaN

To create a new column, use the `[]` brackets with the new column name at the left side of the assignment.

Note: The calculation of the values is done **element_wise**. This means all values in the given column are multiplied

by the value 1.882 at once. You do not need to use a loop to iterate each of the rows!

I want to check the ratio of the values in Paris versus Antwerp and save the result in a new column

```
In [6]: air_quality["ratio_paris_antwerp"] = (
...:     air_quality["station_paris"] / air_quality["station_antwerp"]
...: )
...:

In [7]: air_quality.head()
Out[7]:
            station_antwerp  station_paris  station_london  london_mg_per_cubic
datetime
2019-05-07 02:00:00        NaN          NaN         23.0      43.286
              NaN
2019-05-07 03:00:00        50.5         25.0        19.0      35.758
              0.495050
2019-05-07 04:00:00        45.0         27.7        19.0      35.758
              0.615556
2019-05-07 05:00:00        NaN          50.4        16.0      30.112
              NaN
2019-05-07 06:00:00        NaN          61.9         NaN        NaN
              NaN
```

The calculation is again element-wise, so the `/` is applied *for the values in each row*.

Also other mathematical operators (`+`, `-`, `*`, `/`) or logical operators (`<`, `>`, `=...`) work element wise. The latter was already used in the [subset data tutorial](#) to filter rows of a table using a conditional expression.

If you need more advanced logic, you can use arbitrary Python code via `apply()`.

I want to rename the data columns to the corresponding station identifiers used by openAQ

```
In [8]: air_quality_renamed = air_quality.rename(
...:     columns={
...:         "station_antwerp": "BETR801",
...:         "station_paris": "FR04014",
...:         "station_london": "London Westminster",
...:     }
...: )
```

```
In [9]: air_quality_renamed.head()
Out[9]:
            BETR801  FR04014  London Westminster  london_mg_per_cubic  ratio_
datetime
2019-05-07 02:00:00        NaN          NaN         23.0      43.286
              NaN
2019-05-07 03:00:00        50.5         25.0        19.0      35.758
              0.495050
```

(continues on next page)

(continued from previous page)

The `rename()` function can be used for both row labels and column labels. Provide a dictionary with the keys the current names and the values the new names to update the corresponding names.

The mapping should not be restricted to fixed names only, but can be a mapping function as well. For example, converting the column names to lowercase letters can be done using a function as well:

```
In [10]: air_quality_renamed = air_quality_renamed.rename(columns=str.lower)
```

```
In [11]: air_quality_renamed.head()
```

```
Out[11]:

Details about column or row label renaming is provided in the user guide section on [renaming labels](#).

- Create a new column by assigning the output to the DataFrame with a new column name in between the [].
- Operations are element-wise, no need to loop over rows.
- Use `rename` with a dictionary or function to rename row labels or column names.

The user guide contains a separate section on [column addition and deletion](#).

```
In [1]: import pandas as pd
```

This tutorial uses the Titanic data set, stored as CSV. The data consists of the following data columns:

- PassengerId: Id of every passenger.
- Survived: This feature have value 0 and 1. 0 for not survived and 1 for survived.
- Pclass: There are 3 classes: Class 1, Class 2 and Class 3.
- Name: Name of passenger.
- Sex: Gender of passenger.
- Age: Age of passenger.
- SibSp: Indication that passenger have siblings and spouse.

- Parch: Whether a passenger is alone or have family.
- Ticket: Ticket number of passenger.
- Fare: Indicating the fare.
- Cabin: The cabin of passenger.
- Embarked: The embarked category.

```
In [2]: titanic = pd.read_csv("data/titanic.csv")
```

```
In [3]: titanic.head()
```

How to calculate summary statistics?

Aggregating statistics

What is the average age of the Titanic passengers?

```
In [4]: titanic["Age"].mean()
```

Out[4]: 29.69911764705882

Different statistics are available and can be applied to columns with numerical data. Operations in general exclude missing data and operate across rows by default.

What is the median age and ticket fare price of the Titanic passengers?

```
In [5]: titanic[["Age", "Fare"]].median()
```

Out[5]:

Age	28.0000
Fare	14.4542
dtype:	float64

The statistic applied to multiple columns of a DataFrame (the selection of two columns return a DataFrame, see the [subset data tutorial](#)) is calculated for each numeric column.

The aggregating statistic can be calculated for multiple columns at the same time. Remember the `describe` function from [first tutorial](#)?

```
In [6]: titanic[["Age", "Fare"]].describe()
```

Out[6]:

	Age	Fare
count	714.000000	891.000000
mean	29.699118	32.204208
std	14.526497	49.693429
min	0.420000	0.000000
25%	20.125000	7.910400
50%	28.000000	14.454200
75%	38.000000	31.000000
max	80.000000	512.329200

Instead of the predefined statistics, specific combinations of aggregating statistics for given columns can be defined using the `DataFrame.agg()` method:

```
In [7]: titanic.agg(
```

```
...:     {  
...:         "Age": ["min", "max", "median", "skew"],  
...:         "Fare": ["min", "max", "median", "mean"],  
...:     }  
...: )  
...:
```

Out[7]:

	Age	Fare
min	0.420000	0.000000
max	80.000000	512.329200
median	28.000000	14.454200
skew	0.389108	NaN
mean	NaN	32.204208

Details about descriptive statistics are provided in the user guide section on [descriptive statistics](#).

Aggregating statistics grouped by category

What is the average age for male versus female Titanic passengers?

```
In [8]: titanic[["Sex", "Age"]].groupby("Sex").mean()
```

Out[8]:

Sex	Age
female	27.915709
male	30.726645

As our interest is the average age for each gender, a subselection on these two columns is made first: `titanic[["Sex", "Age"]]`. Next, the `groupby()` method is applied on the `Sex` column to make a group per category. The average age for each gender is calculated and returned.

Calculating a given statistic (e.g. `mean` age) for each category in a column (e.g. male/female in the `Sex` column) is a common pattern. The `groupby` method is used to support this type of operations. More general, this fits in the more general `split-apply-combine` pattern:

- **Split** the data into groups
- **Apply** a function to each group independently
- **Combine** the results into a data structure

The apply and combine steps are typically done together in pandas.

In the previous example, we explicitly selected the 2 columns first. If not, the `mean` method is applied to each column containing numerical columns:

```
In [9]: titanic.groupby("Sex").mean()
Out[9]:
   PassengerId  Survived      Pclass        Age      SibSp      Parch      Fare
Sex
female    431.028662  0.742038  2.159236  27.915709  0.694268  0.649682  44.479818
male     454.147314  0.188908  2.389948  30.726645  0.429809  0.235702  25.523893
```

It does not make much sense to get the average value of the `Pclass`. if we are only interested in the average age for each gender, the selection of columns (rectangular brackets [] as usual) is supported on the grouped data as well:

```
In [10]: titanic.groupby("Sex")["Age"].mean()
Out[10]:
Sex
female    27.915709
male     30.726645
Name: Age, dtype: float64
```

Note: The `Pclass` column contains numerical data but actually represents 3 categories (or factors) with respectively the labels ‘1’, ‘2’ and ‘3’. Calculating statistics on these does not make much sense. Therefore, pandas provides a `Categorical` data type to handle this type of data. More information is provided in the user guide [Categorical data](#) section.

What is the mean ticket fare price for each of the sex and cabin class combinations?

```
In [11]: titanic.groupby(["Sex", "Pclass"])["Fare"].mean()
Out[11]:
Sex   Pclass
female  1       106.125798
          2       21.970121
          3       16.118810
male   1       67.226127
          2       19.741782
          3       12.661633
Name: Fare, dtype: float64
```

Grouping can be done by multiple columns at the same time. Provide the column names as a list to the `groupby()` method.

A full description on the split-apply-combine approach is provided in the user guide section on [groupby operations](#).

Count number of records by category

What is the number of passengers in each of the cabin classes?

```
In [12]: titanic["Pclass"].value_counts()
Out[12]:
3    491
1    216
2    184
Name: Pclass, dtype: int64
```

The `value_counts()` method counts the number of records for each category in a column.

The function is a shortcut, as it is actually a groupby operation in combination with counting of the number of records within each group:

```
In [13]: titanic.groupby("Pclass")["Pclass"].count()
Out[13]:
Pclass
1    216
2    184
3    491
Name: Pclass, dtype: int64
```

Note: Both `size` and `count` can be used in combination with `groupby`. Whereas `size` includes `NaN` values and just provides the number of rows (size of the table), `count` excludes the missing values. In the `value_counts` method, use the `dropna` argument to include or exclude the `NaN` values.

The user guide has a dedicated section on `value_counts`, see page on [discretization](#).

- Aggregation statistics can be calculated on entire columns or rows
- `groupby` provides the power of the *split-apply-combine* pattern
- `value_counts` is a convenient shortcut to count the number of entries in each category of a variable

A full description on the split-apply-combine approach is provided in the user guide pages about [groupby operations](#).

```
In [1]: import pandas as pd
```

This tutorial uses the Titanic data set, stored as CSV. The data consists of the following data columns:

- PassengerId: Id of every passenger.
- Survived: This feature have value 0 and 1. 0 for not survived and 1 for survived.
- Pclass: There are 3 classes: Class 1, Class 2 and Class 3.
- Name: Name of passenger.
- Sex: Gender of passenger.
- Age: Age of passenger.
- SibSp: Indication that passenger have siblings and spouse.
- Parch: Whether a passenger is alone or have family.

- Ticket: Ticket number of passenger.
- Fare: Indicating the fare.
- Cabin: The cabin of passenger.
- Embarked: The embarked category.

```
In [2]: titanic = pd.read_csv("data/titanic.csv")
```

```
In [3]: titanic.head()
```

Out[3]:

	PassengerId	Survived	Pclass	Ticket	Fare	Cabin	Embarked	Name	...
0		1	0	3				Braund, Mr. Owen Harris	...
1	A/5 21171	2	1		7.2500	NaN	S	Cumings, Mrs. John Bradley (Florence Briggs Th...	...
2	PC 17599	3	1		71.2833	C85	C	Heikkinen, Miss. Laina	...
3	STON/O2. 3101282	4	1		7.9250	NaN	S	Futrelle, Mrs. Jacques Heath (Lily May Peel)	...
4	113803	5	0		53.1000	C123	S	Allen, Mr. William Henry	...
	373450				8.0500	NaN	S		

[5 rows x 12 columns]

This tutorial uses air quality data about NO_2 and Particulate matter less than 2.5 micrometers, made available by `openaq` and using the `py-openaq` package. The `air_quality_long.csv` data set provides NO_2 and PM_{25} values for the measurement stations *FR04014*, *BETR801* and *London Westminster* in respectively Paris, Antwerp and London.

The air-quality data set has the following columns:

- city: city where the sensor is used, either Paris, Antwerp or London
- country: country where the sensor is used, either FR, BE or GB
- location: the id of the sensor, either *FR04014*, *BETR801* or *London Westminster*
- parameter: the parameter measured by the sensor, either NO_2 or Particulate matter
- value: the measured value
- unit: the unit of the measured parameter, in this case ‘ $\mu\text{g}/\text{m}^3$ ’

and the index of the DataFrame is `datetime`, the datetime of the measurement.

Note: The air-quality data is provided in a so-called *long format* data representation with each observation on a separate row and each variable a separate column of the data table. The long/narrow format is also known as the `tidy` data format.

```
In [4]: air_quality = pd.read_csv(
...:     "data/air_quality_long.csv", index_col="date.utc", parse_dates=True
...: )
...:
```

```
In [5]: air_quality.head()
```

(continues on next page)

(continued from previous page)

Out[5]:

			city	country	location	parameter	value	unit
date.utc								
2019-06-18	06:00:00+00:00		Antwerpen	BE	BETR801	pm25	18.0	µg/m³

How to reshape the layout of tables?

Sort table rows

I want to sort the Titanic data according to the age of the passengers.

In [6]: titanic.sort_values(by="Age").head()**Out[6]:**

	PassengerId	Survived	Pclass	Name	Sex	Age	SibSp
	Parch	Ticket	Fare Cabin Embarked				
803		804	1	Thomas, Master. Assad Alexander	male	0.42	0
755	1	2625	8.5167	Hamalainen, Master. Viljo	male	0.67	1
644		756	1	Baclini, Miss. Eugenie	female	0.75	2
469		250649	14.5000	Baclini, Miss. Helene Barbara	female	0.75	2
78		2666	19.2583	Baclini, Miss. Eugenie	female	0.75	2
78		470	1	Caldwell, Master. Alden Gates	male	0.83	0
78	2	2666	19.2583	Caldwell, Master. Alden Gates	male	0.83	0
78		248738	29.0000	Caldwell, Master. Alden Gates	male	0.83	0

I want to sort the Titanic data according to the cabin class and age in descending order.

In [7]: titanic.sort_values(by=['Pclass', 'Age'], ascending=False).head()**Out[7]:**

	PassengerId	Survived	Pclass	Name	Sex	Age	SibSp
	Parch	Ticket	Fare Cabin Embarked				
851		852	0	Svensson, Mr. Johan	male	74.0	0
116	0	347060	7.7750	Connors, Mr. Patrick	male	70.5	0
280		117	NaN	Duane, Mr. Frank	male	65.0	0
483		370369	7.7500	Turkula, Mrs. (Hedwig)	female	63.0	0
326		281	0	Nysveen, Mr. Johan Hansen	male	61.0	0
326	0	4134	7.7500	Nysveen, Mr. Johan Hansen	male	61.0	0
326		484	1	Turkula, Mrs. (Hedwig)	female	63.0	0
345364	0	336439	9.5875	Nysveen, Mr. Johan Hansen	male	61.0	0
345364		327	NaN	Nysveen, Mr. Johan Hansen	male	61.0	0
345364		6.2375	S	Nysveen, Mr. Johan Hansen	male	61.0	0

With `Series.sort_values()`, the rows in the table are sorted according to the defined column(s). The index will follow the row order.

More details about sorting of tables is provided in the using guide section on [sorting data](#).

Long to wide table format

Let's use a small subset of the air quality data set. We focus on NO_2 data and only use the first two measurements of each location (i.e. the head of each group). The subset of data will be called `no2_subset`

```
# filter for no2 data only
In [8]: no2 = air_quality[air_quality["parameter"] == "no2"]
```

```
# use 2 measurements (head) for each location (groupby)
In [9]: no2_subset = no2.sort_index().groupby(["location"]).head(2)
```

In [10]: `no2_subset`

Out[10]:

	city	country	location	parameter	value	unit
date.utc						
2019-04-09 01:00:00+00:00	Antwerpen	BE	BETR801	no2	22.5	$\mu\text{g}/\text{m}^3$
2019-04-09 01:00:00+00:00	Paris	FR	FR04014	no2	24.4	$\mu\text{g}/\text{m}^3$
2019-04-09 02:00:00+00:00	London	GB	London Westminster	no2	67.0	$\mu\text{g}/\text{m}^3$
2019-04-09 02:00:00+00:00	Antwerpen	BE	BETR801	no2	53.5	$\mu\text{g}/\text{m}^3$
2019-04-09 02:00:00+00:00	Paris	FR	FR04014	no2	27.4	$\mu\text{g}/\text{m}^3$
2019-04-09 03:00:00+00:00	London	GB	London Westminster	no2	67.0	$\mu\text{g}/\text{m}^3$

I want the values for the three stations as separate columns next to each other

```
In [11]: no2_subset.pivot(columns="location", values="value")
```

Out[11]:

location	BETR801	FR04014	London Westminster
date.utc			
2019-04-09 01:00:00+00:00	22.5	24.4	NaN
2019-04-09 02:00:00+00:00	53.5	27.4	67.0
2019-04-09 03:00:00+00:00	NaN	NaN	67.0

The `pivot()` function is purely reshaping of the data: a single value for each index/column combination is required.

As pandas support plotting of multiple columns (see [plotting tutorial](#)) out of the box, the conversion from *long* to *wide* table format enables the plotting of the different time series at the same time:

In [12]: `no2.head()`

Out[12]:

	city	country	location	parameter	value	unit
date.utc						
2019-06-21 00:00:00+00:00	Paris	FR	FR04014	no2	20.0	$\mu\text{g}/\text{m}^3$
2019-06-20 23:00:00+00:00	Paris	FR	FR04014	no2	21.8	$\mu\text{g}/\text{m}^3$
2019-06-20 22:00:00+00:00	Paris	FR	FR04014	no2	26.5	$\mu\text{g}/\text{m}^3$
2019-06-20 21:00:00+00:00	Paris	FR	FR04014	no2	24.9	$\mu\text{g}/\text{m}^3$
2019-06-20 20:00:00+00:00	Paris	FR	FR04014	no2	21.4	$\mu\text{g}/\text{m}^3$

```
In [13]: no2.pivot(columns="location", values="value").plot()
```

Out[13]: <AxesSubplot:xlabel='date.utc'>

Note: When the `index` parameter is not defined, the existing index (row labels) is used.

For more information about `pivot()`, see the user guide section on [pivoting DataFrame objects](#).

Pivot table

I want the mean concentrations for NO_2 and $PM_{2.5}$ in each of the stations in table form

```
In [14]: air_quality.pivot_table(  
.....    values="value", index="location", columns="parameter", aggfunc="mean"  
.....)  
.....  
Out[14]:  
parameter          no2      pm25  
location  
BETR801        26.950920  23.169492  
FR04014        29.374284      NaN  
London Westminster 29.740050  13.443568
```

In the case of `pivot()`, the data is only rearranged. When multiple values need to be aggregated (in this specific case,

the values on different time steps) `pivot_table()` can be used, providing an aggregation function (e.g. mean) on how to combine these values.

Pivot table is a well known concept in spreadsheet software. When interested in summary columns for each variable separately as well, put the `margin` parameter to `True`:

```
In [15]: air_quality.pivot_table(
.....    values="value",
.....    index="location",
.....    columns="parameter",
.....    aggfunc="mean",
.....    margins=True,
.....)
.....
Out[15]:
parameter          no2        pm25      All
location
BETR801           26.950920  23.169492  24.982353
FR04014           29.374284      NaN     29.374284
London Westminster 29.740050  13.443568  21.491708
All                29.430316  14.386849  24.222743
```

For more information about `pivot_table()`, see the user guide section on [pivot tables](#).

Note: In case you are wondering, `pivot_table()` is indeed directly linked to `groupby()`. The same result can be derived by grouping on both `parameter` and `location`:

```
air_quality.groupby(["parameter", "location"]).mean()
```

Have a look at `groupby()` in combination with `unstack()` at the user guide section on [combining stats and groupby](#).

Wide to long format

Starting again from the wide format table created in the previous section:

```
In [16]: no2_pivoted = no2.pivot(columns="location", values="value").reset_index()
```

```
In [17]: no2_pivoted.head()
```

Out[17]:

location	date.utc	BETR801	FR04014	London Westminster
0	2019-04-09 01:00:00+00:00	22.5	24.4	NaN
1	2019-04-09 02:00:00+00:00	53.5	27.4	67.0
2	2019-04-09 03:00:00+00:00	54.5	34.2	67.0
3	2019-04-09 04:00:00+00:00	34.5	48.5	41.0
4	2019-04-09 05:00:00+00:00	46.5	59.5	41.0

I want to collect all air quality NO_2 measurements in a single column (long format)

```
In [18]: no_2 = no2_pivoted.melt(id_vars="date.utc")
```

(continues on next page)

(continued from previous page)

In [19]: no_2.head()**Out[19]:**

	date.utc	location	value
0	2019-04-09 01:00:00+00:00	BETR801	22.5
1	2019-04-09 02:00:00+00:00	BETR801	53.5
2	2019-04-09 03:00:00+00:00	BETR801	54.5
3	2019-04-09 04:00:00+00:00	BETR801	34.5
4	2019-04-09 05:00:00+00:00	BETR801	46.5

The `pandas.melt()` method on a DataFrame converts the data table from wide format to long format. The column headers become the variable names in a newly created column.

The solution is the short version on how to apply `pandas.melt()`. The method will *melt* all columns NOT mentioned in `id_vars` together into two columns: A column with the column header names and a column with the values itself. The latter column gets by default the name `value`.

The `pandas.melt()` method can be defined in more detail:

```
In [20]: no_2 = no2_pivoted.melt(
    ....:     id_vars="date.utc",
    ....:     value_vars=["BETR801", "FR04014", "London Westminster"],
    ....:     value_name="NO_2",
    ....:     var_name="id_location",
    ....: )
....:
```

In [21]: no_2.head()**Out[21]:**

	date.utc	id_location	NO_2
0	2019-04-09 01:00:00+00:00	BETR801	22.5
1	2019-04-09 02:00:00+00:00	BETR801	53.5
2	2019-04-09 03:00:00+00:00	BETR801	54.5
3	2019-04-09 04:00:00+00:00	BETR801	34.5
4	2019-04-09 05:00:00+00:00	BETR801	46.5

The result is the same, but in more detail defined:

- `value_vars` defines explicitly which columns to *melt* together
- `value_name` provides a custom column name for the values column instead of the default column name `value`
- `var_name` provides a custom column name for the column collecting the column header names. Otherwise it takes the index name or a default variable

Hence, the arguments `value_name` and `var_name` are just user-defined names for the two generated columns. The columns to melt are defined by `id_vars` and `value_vars`.

Conversion from wide to long format with `pandas.melt()` is explained in the user guide section on *reshaping by melt*.

- Sorting by one or more columns is supported by `sort_values`
- The `pivot` function is purely restructuring of the data, `pivot_table` supports aggregations
- The reverse of `pivot` (long to wide format) is `melt` (wide to long format)

A full overview is available in the user guide on the pages about *reshaping and pivoting*.

```
In [1]: import pandas as pd
```

For this tutorial, air quality data about NO_2 is used, made available by `openaq` and downloaded using the `py-openaq` package.

The `air_quality_no2_long.csv` data set provides NO_2 values for the measurement stations *FR04014*, *BETR801* and *London Westminster* in respectively Paris, Antwerp and London.

```
In [2]: air_quality_no2 = pd.read_csv("data/air_quality_no2_long.csv",
...:                                     parse_dates=True)
...:

In [3]: air_quality_no2 = air_quality_no2[["date.utc", "location",
...:                                         "parameter", "value"]]
...:

In [4]: air_quality_no2.head()
Out[4]:
      date.utc    location parameter  value
0  2019-06-21 00:00:00+00:00  FR04014      no2   20.0
1  2019-06-20 23:00:00+00:00  FR04014      no2   21.8
2  2019-06-20 22:00:00+00:00  FR04014      no2   26.5
3  2019-06-20 21:00:00+00:00  FR04014      no2   24.9
4  2019-06-20 20:00:00+00:00  FR04014      no2   21.4
```

For this tutorial, air quality data about Particulate matter less than 2.5 micrometers is used, made available by `openaq` and downloaded using the `py-openaq` package.

The `air_quality_pm25_long.csv` data set provides PM_{25} values for the measurement stations *FR04014*, *BETR801* and *London Westminster* in respectively Paris, Antwerp and London.

```
In [5]: air_quality_pm25 = pd.read_csv("data/air_quality_pm25_long.csv",
...:                                     parse_dates=True)
...:

In [6]: air_quality_pm25 = air_quality_pm25[["date.utc", "location",
...:                                         "parameter", "value"]]
...:

In [7]: air_quality_pm25.head()
Out[7]:
      date.utc    location parameter  value
0  2019-06-18 06:00:00+00:00  BETR801      pm25   18.0
1  2019-06-17 08:00:00+00:00  BETR801      pm25    6.5
2  2019-06-17 07:00:00+00:00  BETR801      pm25   18.5
3  2019-06-17 06:00:00+00:00  BETR801      pm25   16.0
4  2019-06-17 05:00:00+00:00  BETR801      pm25    7.5
```

How to combine data from multiple tables?

Concatenating objects

I want to combine the measurements of NO_2 and PM_{25} , two tables with a similar structure, in a single table

```
In [8]: air_quality = pd.concat([air_quality_pm25, air_quality_no2], axis=0)
```

```
In [9]: air_quality.head()
```

```
Out[9]:
```

	date.utc	location	parameter	value
0	2019-06-18 06:00:00+00:00	BETR801	pm25	18.0
1	2019-06-17 08:00:00+00:00	BETR801	pm25	6.5
2	2019-06-17 07:00:00+00:00	BETR801	pm25	18.5
3	2019-06-17 06:00:00+00:00	BETR801	pm25	16.0
4	2019-06-17 05:00:00+00:00	BETR801	pm25	7.5

The `concat()` function performs concatenation operations of multiple tables along one of the axis (row-wise or column-wise).

By default concatenation is along axis 0, so the resulting table combines the rows of the input tables. Let's check the shape of the original and the concatenated tables to verify the operation:

```
In [10]: print('Shape of the ``air_quality_pm25`` table: ', air_quality_pm25.shape)
Shape of the ``air_quality_pm25`` table: (1110, 4)
```

```
In [11]: print('Shape of the ``air_quality_no2`` table: ', air_quality_no2.shape)
Shape of the ``air_quality_no2`` table: (2068, 4)
```

```
In [12]: print('Shape of the resulting ``air_quality`` table: ', air_quality.shape)
Shape of the resulting ``air_quality`` table: (3178, 4)
```

Hence, the resulting table has $3178 = 1110 + 2068$ rows.

Note: The `axis` argument will return in a number of pandas methods that can be applied **along an axis**. A DataFrame has two corresponding axes: the first running vertically downwards across rows (axis 0), and the second running horizontally across columns (axis 1). Most operations like concatenation or summary statistics are by default across rows (axis 0), but can be applied across columns as well.

Sorting the table on the datetime information illustrates also the combination of both tables, with the `parameter` column defining the origin of the table (either `no2` from table `air_quality_no2` or `pm25` from table `air_quality_pm25`):

```
In [13]: air_quality = air_quality.sort_values("date.utc")
```

```
In [14]: air_quality.head()
```

```
Out[14]:
```

	date.utc	location	parameter	value
2067	2019-05-07 01:00:00+00:00	London Westminster	no2	23.0
1003	2019-05-07 01:00:00+00:00	FR04014	no2	25.0
100	2019-05-07 01:00:00+00:00	BETR801	pm25	12.5

(continues on next page)

(continued from previous page)

1098	2019-05-07 01:00:00+00:00	BETR801	no2	50.5
1109	2019-05-07 01:00:00+00:00	London Westminster	pm25	8.0

In this specific example, the `parameter` column provided by the data ensures that each of the original tables can be identified. This is not always the case. the `concat` function provides a convenient solution with the `keys` argument, adding an additional (hierarchical) row index. For example:

```
In [15]: air_quality_ = pd.concat([air_quality_pm25, air_quality_no2], keys=["PM25", "NO2"])
          ↪ ])
```

```
In [16]: air_quality_.head()
```

```
Out[16]:
```

		date.utc	location	parameter	value
PM25	0	2019-06-18 06:00:00+00:00	BETR801	pm25	18.0
	1	2019-06-17 08:00:00+00:00	BETR801	pm25	6.5
	2	2019-06-17 07:00:00+00:00	BETR801	pm25	18.5
	3	2019-06-17 06:00:00+00:00	BETR801	pm25	16.0
	4	2019-06-17 05:00:00+00:00	BETR801	pm25	7.5

Note: The existence of multiple row/column indices at the same time has not been mentioned within these tutorials. *Hierarchical indexing* or *MultiIndex* is an advanced and powerful pandas feature to analyze higher dimensional data.

Multi-indexing is out of scope for this pandas introduction. For the moment, remember that the function `reset_index` can be used to convert any level of an index to a column, e.g. `air_quality.reset_index(level=0)`

Feel free to dive into the world of multi-indexing at the user guide section on [advanced indexing](#).

More options on table concatenation (row and column wise) and how `concat` can be used to define the logic (union or intersection) of the indexes on the other axes is provided at the section on [object concatenation](#).

Join tables using a common identifier

Add the station coordinates, provided by the stations metadata table, to the corresponding rows in the measurements table.

Warning: The air quality measurement station coordinates are stored in a data file `air_quality_stations.csv`, downloaded using the `py-openaq` package.

```
In [17]: stations_coord = pd.read_csv("data/air_quality_stations.csv")
```

```
In [18]: stations_coord.head()
```

```
Out[18]:
```

	location	coordinates.latitude	coordinates.longitude
0	BELAL01	51.23619	4.38522
1	BELHB23	51.17030	4.34100
2	BELL01	51.10998	5.00486
3	BELLD02	51.12038	5.02155
4	BELR833	51.32766	4.36226

Note: The stations used in this example (FR04014, BETR801 and London Westminster) are just three entries enlisted in the metadata table. We only want to add the coordinates of these three to the measurements table, each on the corresponding rows of the air_quality table.

In [19]: `air_quality.head()`

Out[19]:

		date.utc	location	parameter	value
2067	2019-05-07 01:00:00+00:00	London	Westminster	no2	23.0
1003	2019-05-07 01:00:00+00:00		FR04014	no2	25.0
100	2019-05-07 01:00:00+00:00		BETR801	pm25	12.5
1098	2019-05-07 01:00:00+00:00		BETR801	no2	50.5
1109	2019-05-07 01:00:00+00:00	London	Westminster	pm25	8.0

In [20]: `air_quality = pd.merge(air_quality, stations_coord, how="left", on="location")`

In [21]: `air_quality.head()`

Out[21]:

		date.utc	location	parameter	value	coordinates.latitude	coordinates.longitude
0	2019-05-07 01:00:00+00:00	London	Westminster	no2	23.0	51.49467	-0.13193
1	2019-05-07 01:00:00+00:00		FR04014	no2	25.0	48.83724	2.39390
2	2019-05-07 01:00:00+00:00		FR04014	no2	25.0	48.83722	2.39390
3	2019-05-07 01:00:00+00:00		BETR801	pm25	12.5	51.20966	4.43182
4	2019-05-07 01:00:00+00:00		BETR801	no2	50.5	51.20966	4.43182

Using the `merge()` function, for each of the rows in the air_quality table, the corresponding coordinates are added from the air_quality_stations_coord table. Both tables have the column location in common which is used as a key to combine the information. By choosing the left join, only the locations available in the air_quality (left) table, i.e. FR04014, BETR801 and London Westminster, end up in the resulting table. The merge function supports multiple join options similar to database-style operations.

Add the parameter full description and name, provided by the parameters metadata table, to the measurements table

Warning: The air quality parameters metadata are stored in a data file `air_quality_parameters.csv`, downloaded using the `py-openaq` package.

In [22]: `air_quality_parameters = pd.read_csv("data/air_quality_parameters.csv")`

In [23]: `air_quality_parameters.head()`

Out[23]:

	id	description	name
0	bc	Black Carbon	BC
1	co	Carbon Monoxide	CO
2	no2	Nitrogen Dioxide	NO2
3	o3	Ozone	O3

(continues on next page)

(continued from previous page)

```
4 pm10 Particulate matter less than 10 micrometers in... PM10
```

```
In [24]: air_quality = pd.merge(air_quality, air_quality_parameters,
.....:                               how='left', left_on='parameter', right_on='id')
.....:
```

```
In [25]: air_quality.head()
```

```
Out[25]:
```

	date.utc	location	parameter	...	id	
	description	name				
0	2019-05-07 01:00:00+00:00	London	Westminster	no2	...	no2
	Nitrogen Dioxide	NO2				
1	2019-05-07 01:00:00+00:00		FR04014	no2	...	no2
	Nitrogen Dioxide	NO2				
2	2019-05-07 01:00:00+00:00		FR04014	no2	...	no2
	Nitrogen Dioxide	NO2				
3	2019-05-07 01:00:00+00:00		BETR801	pm25	...	pm25 Particulate
	matter less than 2.5 micrometers i...	PM2.5				
4	2019-05-07 01:00:00+00:00		BETR801	no2	...	no2
	Nitrogen Dioxide	NO2				

```
[5 rows x 9 columns]
```

Compared to the previous example, there is no common column name. However, the `parameter` column in the `air_quality` table and the `id` column in the `air_quality_parameters_name` both provide the measured variable in a common format. The `left_on` and `right_on` arguments are used here (instead of just `on`) to make the link between the two tables.

pandas supports also inner, outer, and right joins. More information on join/merge of tables is provided in the user guide section on [database style merging of tables](#). Or have a look at the [comparison with SQL](#) page.

- Multiple tables can be concatenated both column-wise and row-wise using the `concat` function.
- For database-like merging/joining of tables, use the `merge` function.

See the user guide for a full description of the various [facilities to combine data tables](#).

```
In [1]: import pandas as pd
```

```
In [2]: import matplotlib.pyplot as plt
```

For this tutorial, air quality data about NO_2 and Particulate matter less than 2.5 micrometers is used, made available by `openaq` and downloaded using the `py-openaq` package. The `air_quality_no2_long.csv` data set provides NO_2 values for the measurement stations `FR04014`, `BETR801` and `London Westminster` in respectively Paris, Antwerp and London.

```
In [3]: air_quality = pd.read_csv("data/air_quality_no2_long.csv")
```

```
In [4]: air_quality = air_quality.rename(columns={"date.utc": "datetime"})
```

```
In [5]: air_quality.head()
```

```
Out[5]:
```

	city	country	datetime	location	parameter	value	unit

In [6]: `air_quality.city.unique()`

Out[6]: `array(['Paris', 'Antwerpen', 'London'], dtype=object)`

How to handle time series data with ease?

Using pandas datetime properties

I want to work with the dates in the column `datetime` as datetime objects instead of plain text

In [7]: `air_quality["datetime"] = pd.to_datetime(air_quality["datetime"])`

In [8]: `air_quality["datetime"]`

Out[8]:

```
0    2019-06-21 00:00:00+00:00
1    2019-06-20 23:00:00+00:00
2    2019-06-20 22:00:00+00:00
3    2019-06-20 21:00:00+00:00
4    2019-06-20 20:00:00+00:00
...
2063   2019-05-07 06:00:00+00:00
2064   2019-05-07 04:00:00+00:00
2065   2019-05-07 03:00:00+00:00
2066   2019-05-07 02:00:00+00:00
2067   2019-05-07 01:00:00+00:00
Name: datetime, Length: 2068, dtype: datetime64[ns, UTC]
```

Initially, the values in `datetime` are character strings and do not provide any datetime operations (e.g. extract the year, day of the week,...). By applying the `to_datetime` function, pandas interprets the strings and convert these to datetime (i.e. `datetime64[ns, UTC]`) objects. In pandas we call these datetime objects similar to `datetime.datetime` from the standard library as `pandas.Timestamp`.

Note: As many data sets do contain datetime information in one of the columns, pandas input function like `pandas.read_csv()` and `pandas.read_json()` can do the transformation to dates when reading the data using the `parse_dates` parameter with a list of the columns to read as Timestamp:

`pd.read_csv("../data/air_quality_no2_long.csv", parse_dates=["datetime"])`

Why are these `pandas.Timestamp` objects useful? Let's illustrate the added value with some example cases.

What is the start and end date of the time series data set we are working with?

In [9]: `air_quality["datetime"].min(), air_quality["datetime"].max()`

Out[9]:

```
(Timestamp('2019-05-07 01:00:00+0000', tz='UTC'),
 Timestamp('2019-06-21 00:00:00+0000', tz='UTC'))
```

Using `pandas.Timestamp` for datetimes enables us to calculate with date information and make them comparable. Hence, we can use this to get the length of our time series:

```
In [10]: air_quality["datetime"].max() - air_quality["datetime"].min()
Out[10]: Timedelta('44 days 23:00:00')
```

The result is a `pandas.Timedelta` object, similar to `datetime.timedelta` from the standard Python library and defining a time duration.

The various time concepts supported by pandas are explained in the user guide section on [time related concepts](#).

I want to add a new column to the DataFrame containing only the month of the measurement

```
In [11]: air_quality["month"] = air_quality["datetime"].dt.month
```

```
In [12]: air_quality.head()
```

```
Out[12]:
```

	city	country	datetime	location	parameter	value	unit	month
0	Paris	FR	2019-06-21 00:00:00+00:00	FR04014	no2	20.0	µg/m³	6
1	Paris	FR	2019-06-20 23:00:00+00:00	FR04014	no2	21.8	µg/m³	6
2	Paris	FR	2019-06-20 22:00:00+00:00	FR04014	no2	26.5	µg/m³	6
3	Paris	FR	2019-06-20 21:00:00+00:00	FR04014	no2	24.9	µg/m³	6
4	Paris	FR	2019-06-20 20:00:00+00:00	FR04014	no2	21.4	µg/m³	6

By using `Timestamp` objects for dates, a lot of time-related properties are provided by pandas. For example the `month`, but also `year`, `weekofyear`, `quarter`,... All of these properties are accessible by the `dt` accessor.

An overview of the existing date properties is given in the [time and date components overview table](#). More details about the `dt` accessor to return datetime like properties are explained in a dedicated section on the [dt accessor](#).

What is the average NO_2 concentration for each day of the week for each of the measurement locations?

```
In [13]: air_quality.groupby(
    ....:     [air_quality["datetime"].dt.weekday, "location"])["value"].mean()
    ....:
```

```
Out[13]:
```

	datetime	location	value
0		BETR801	27.875000
		FR04014	24.856250
		London Westminster	23.969697
1		BETR801	22.214286
		FR04014	30.999359
			...
5		FR04014	25.266154
		London Westminster	24.977612
6		BETR801	21.896552
		FR04014	23.274306
		London Westminster	24.859155

Name: value, Length: 21, dtype: float64

Remember the split-apply-combine pattern provided by `groupby` from the [tutorial on statistics calculation](#)? Here, we want to calculate a given statistic (e.g. mean NO_2) **for each weekday** and **for each measurement location**. To group on weekdays, we use the `datetime` property `weekday` (with Monday=0 and Sunday=6) of pandas `Timestamp`, which is also accessible by the `dt` accessor. The grouping on both locations and weekdays can be done to split the calculation of the mean on each of these combinations.

Danger: As we are working with a very short time series in these examples, the analysis does not provide a long-term representative result!

Plot the typical NO_2 pattern during the day of our time series of all stations together. In other words, what is the average value for each hour of the day?

```
In [14]: fig, axs = plt.subplots(figsize=(12, 4))

In [15]: air_quality.groupby(air_quality["datetime"].dt.hour)[ "value" ].mean().plot(
.....:     kind='bar', rot=0, ax=axs
.....: )
.....:

Out[15]: <AxesSubplot:xlabel='datetime'>

In [16]: plt.xlabel("Hour of the day"); # custom x label using matplotlib

In [17]: plt.ylabel("$NO_2$ ($\mu g/m^3$)");
```

Similar to the previous case, we want to calculate a given statistic (e.g. mean NO_2) **for each hour of the day** and we can use the split-apply-combine approach again. For this case, we use the datetime property hour of pandas Timestamp, which is also accessible by the dt accessor.

Datetime as index

In the [tutorial on reshaping](#), `pivot()` was introduced to reshape the data table with each of the measurements locations as a separate column:

```
In [18]: no_2 = air_quality.pivot(index="datetime", columns="location", values="value")
```

```
In [19]: no_2.head()
```

```
Out[19]:
location          BETR801  FR04014  London  Westminster
datetime
2019-05-07 01:00:00+00:00      50.5      25.0        23.0
2019-05-07 02:00:00+00:00      45.0      27.7        19.0
2019-05-07 03:00:00+00:00      NaN      50.4        19.0
2019-05-07 04:00:00+00:00      NaN      61.9        16.0
2019-05-07 05:00:00+00:00      NaN      72.4        NaN
```

Note: By pivoting the data, the datetime information became the index of the table. In general, setting a column as an index can be achieved by the `set_index` function.

Working with a datetime index (i.e. `DatetimeIndex`) provides powerful functionalities. For example, we do not need the `dt` accessor to get the time series properties, but have these properties available on the index directly:

```
In [20]: no_2.index.year, no_2.index.weekday
Out[20]:
(Int64Index([2019, 2019, 2019, 2019, 2019, 2019, 2019, 2019, 2019, 2019,
             ...,
             2019, 2019, 2019, 2019, 2019, 2019, 2019, 2019, 2019, 2019],
            dtype='int64', name='datetime', length=1033),
 Int64Index([1, 1, 1, 1, 1, 1, 1, 1, 1, 1,
             ...,
             3, 3, 3, 3, 3, 3, 3, 3, 3, 4],
            dtype='int64', name='datetime', length=1033))
```

Some other advantages are the convenient subsetting of time period or the adapted time scale on plots. Let's apply this on our data.

Create a plot of the NO_2 values in the different stations from the 20th of May till the end of 21st of May

```
In [21]: no_2["2019-05-20":"2019-05-21"].plot();
```

By providing a **string that parses to a datetime**, a specific subset of the data can be selected on a `DatetimeIndex`. More information on the `DatetimeIndex` and the slicing by using strings is provided in the section on [time series indexing](#).

Resample a time series to another frequency

Aggregate the current hourly time series values to the monthly maximum value in each of the stations.

```
In [22]: monthly_max = no_2.resample("M").max()
```

```
In [23]: monthly_max
```

```
Out[23]:
```

location	BETR801	FR04014	London Westminster
datetime			
2019-05-31 00:00:00+00:00	74.5	97.0	97.0
2019-06-30 00:00:00+00:00	52.5	84.7	52.0

A very powerful method on time series data with a datetime index, is the ability to `resample()` time series to another frequency (e.g., converting secondly data into 5-minute data).

The `resample()` method is similar to a groupby operation:

- it provides a time-based grouping, by using a string (e.g. M, 5H,...) that defines the target frequency
- it requires an aggregation function such as `mean`, `max`,...

An overview of the aliases used to define time series frequencies is given in the [offset aliases overview table](#).

When defined, the frequency of the time series is provided by the `freq` attribute:

```
In [24]: monthly_max.index.freq
```

```
Out[24]: <MonthEnd>
```

Make a plot of the daily mean NO_2 value in each of the stations.

```
In [25]: no_2.resample("D").mean().plot(style="-o", figsize=(10, 5));
```

More details on the power of time series [resampling](#) is provided in the user guide section on [resampling](#).

- Valid date strings can be converted to datetime objects using `to_datetime` function or as part of read functions.
- Datetime objects in pandas support calculations, logical operations and convenient date-related properties using the `dt` accessor.
- A `DatetimeIndex` contains these date-related properties and supports convenient slicing.
- `Resample` is a powerful method to change the frequency of a time series.

A full overview on time series is given on the pages on [time series and date functionality](#).

```
In [1]: import pandas as pd
```

This tutorial uses the Titanic data set, stored as CSV. The data consists of the following data columns:

- PassengerId: Id of every passenger.
- Survived: This feature have value 0 and 1. 0 for not survived and 1 for survived.
- Pclass: There are 3 classes: Class 1, Class 2 and Class 3.
- Name: Name of passenger.
- Sex: Gender of passenger.
- Age: Age of passenger.
- SibSp: Indication that passenger have siblings and spouse.
- Parch: Whether a passenger is alone or have family.
- Ticket: Ticket number of passenger.
- Fare: Indicating the fare.
- Cabin: The cabin of passenger.
- Embarked: The embarked category.

```
In [2]: titanic = pd.read_csv("data/titanic.csv")
```

```
In [3]: titanic.head()
```

```
Out[3]:
```

	PassengerId	Survived	Pclass	Ticket	Fare	Cabin	Embarked	Name
0		1	3	A/5 21171	7.2500	NaN	S	Braund, Mr. Owen Harris
1		2	1	CUMINGS, Mrs. John Bradley (Florence Briggs Th...	1.0	1	C	Cumings, Mrs. John Bradley (Florence Briggs Th...
2		3	3	PC 17599	71.2833	C85		Heikkinen, Miss. Laina
3		4	1	STON/O2. 3101282	7.9250	NaN	S	Futrelle, Mrs. Jacques Heath (Lily May Peel)
4		5	3	113803	53.1000	C123	S	Allen, Mr. William Henry
				373450	8.0500	NaN	S	

[5 rows x 12 columns]

How to manipulate textual data?

Make all name characters lowercase.

```
In [4]: titanic["Name"].str.lower()
```

```
Out[4]:
```

0	braund, mr. owen harris
1	cumings, mrs. john bradley (florence briggs th...
2	heikkinen, miss. laina
3	futrelle, mrs. jacques heath (lily may peel)
4	allen, mr. william henry
...	
886	montvila, rev. juozas
887	graham, miss. margaret edith
888	johnston, miss. catherine helen "carrie"
889	behr, mr. karl howell
890	dooley, mr. patrick

Name: Name, Length: 891, dtype: object

To make each of the strings in the Name column lowercase, select the Name column (see the [tutorial on selection of data](#)), add the str accessor and apply the lower method. As such, each of the strings is converted element-wise.

Similar to datetime objects in the [time series tutorial](#) having a dt accessor, a number of specialized string methods are available when using the str accessor. These methods have in general matching names with the equivalent built-in string methods for single elements, but are applied element-wise (remember [element-wise calculations](#)?) on each of the values of the columns.

Create a new column Surname that contains the surname of the passengers by extracting the part before the comma.

```
In [5]: titanic["Name"].str.split(",")
```

```
Out[5]:
```

0	[Braund, Mr. Owen Harris]
1	[Cumings, Mrs. John Bradley (Florence Briggs ...]
2	[Heikkinen, Miss. Laina]

(continues on next page)

(continued from previous page)

```

3      [Futrelle, Mrs. Jacques Heath (Lily May Peel)]
4          [Allen, Mr. William Henry]
...
886          [Montvila, Rev. Juozas]
887          [Graham, Miss. Margaret Edith]
888          [Johnston, Miss. Catherine Helen "Carrie"]
889          [Behr, Mr. Karl Howell]
890          [Dooley, Mr. Patrick]
Name: Name, Length: 891, dtype: object

```

Using the `Series.str.split()` method, each of the values is returned as a list of 2 elements. The first element is the part before the comma and the second element is the part after the comma.

```
In [6]: titanic["Surname"] = titanic["Name"].str.split(",") str.get(0)
```

```
In [7]: titanic["Surname"]
```

```
Out[7]:
```

```

0      Braund
1      Cumings
2      Heikkinen
3      Futrelle
4      Allen
...
886     Montvila
887     Graham
888     Johnston
889     Behr
890     Dooley
Name: Surname, Length: 891, dtype: object

```

As we are only interested in the first part representing the surname (element 0), we can again use the `str` accessor and apply `Series.str.get()` to extract the relevant part. Indeed, these string functions can be concatenated to combine multiple functions at once!

More information on extracting parts of strings is available in the user guide section on [splitting and replacing strings](#).

Extract the passenger data about the countesses on board of the Titanic.

```
In [8]: titanic["Name"].str.contains("Countess")
```

```
Out[8]:
```

```

0      False
1      False
2      False
3      False
4      False
...
886     False
887     False
888     False
889     False
890     False
Name: Name, Length: 891, dtype: bool

```

```
In [9]: titanic[titanic["Name"].str.contains("Countess")]
Out[9]:
   PassengerId  Survived  Pclass          Name
   ↓ Sex  ...  Ticket  Cabin Embarked  Surname
759           1       1      1  Rothes, the Countess. of (Lucy Noel Martha Dye...
   ↓female  ...  110152  86.5      B77          S  Rothes
[1 rows x 13 columns]
```

(Interested in her story? See [Wikipedia!](#))

The string method `Series.str.contains()` checks for each of the values in the column `Name` if the string contains the word `Countess` and returns for each of the values `True` (`Countess` is part of the name) or `False` (`Countess` is not part of the name). This output can be used to subselect the data using conditional (boolean) indexing introduced in the [subsetting of data tutorial](#). As there was only one countess on the Titanic, we get one row as a result.

Note: More powerful extractions on strings are supported, as the `Series.str.contains()` and `Series.str.extract()` methods accept [regular expressions](#), but out of scope of this tutorial.

More information on extracting parts of strings is available in the user guide section on [string matching and extracting](#).

Which passenger of the Titanic has the longest name?

```
In [10]: titanic["Name"].str.len()
Out[10]:
0      23
1      51
2      22
3      44
4      24
..
886     21
887     28
888     40
889     21
890     19
Name: Name, Length: 891, dtype: int64
```

To get the longest name we first have to get the lengths of each of the names in the `Name` column. By using pandas string methods, the `Series.str.len()` function is applied to each of the names individually (element-wise).

```
In [11]: titanic["Name"].str.len().idxmax()
Out[11]: 307
```

Next, we need to get the corresponding location, preferably the index label, in the table for which the name length is the largest. The `idxmax()` method does exactly that. It is not a string method and is applied to integers, so no `str` is used.

```
In [12]: titanic.loc[titanic["Name"].str.len().idxmax(), "Name"]
Out[12]: 'Penasco y Castellana, Mrs. Victor de Satode (Maria Josefa Perez de Soto y...
   ↓Vallejo)'
```

Based on the index name of the row (307) and the column (`Name`), we can do a selection using the `loc` operator, introduced in the [tutorial on subsetting](#).

In the “Sex” column, replace values of “male” by “M” and values of “female” by “F”.

```
In [13]: titanic["Sex_short"] = titanic["Sex"].replace({"male": "M", "female": "F"})

In [14]: titanic["Sex_short"]
Out[14]:
0      M
1      F
2      F
3      F
4      M
...
886     M
887     F
888     F
889     M
890     M
Name: Sex_short, Length: 891, dtype: object
```

Whereas `replace()` is not a string method, it provides a convenient way to use mappings or vocabularies to translate certain values. It requires a dictionary to define the mapping `{from : to}`.

Warning: There is also a `replace()` method available to replace a specific set of characters. However, when having a mapping of multiple values, this would become:

```
titanic["Sex_short"] = titanic["Sex"].str.replace("female", "F")
titanic["Sex_short"] = titanic["Sex_short"].str.replace("male", "M")
```

This would become cumbersome and easily lead to mistakes. Just think (or try out yourself) what would happen if those two statements are applied in the opposite order...

- String methods are available using the `str` accessor.
- String methods work element-wise and can be used for conditional indexing.
- The `replace` method is a convenient method to convert values according to a given dictionary.

A full overview is provided in the user guide pages on [working with text data](#).

1.4.4 Comparison with other tools

Comparison with R / R libraries

Since pandas aims to provide a lot of the data manipulation and analysis functionality that people use R for, this page was started to provide a more detailed look at the [R language](#) and its many third party libraries as they relate to pandas. In comparisons with R and CRAN libraries, we care about the following things:

- **Functionality / flexibility:** what can/cannot be done with each tool
- **Performance:** how fast are operations. Hard numbers/benchmarks are preferable
- **Ease-of-use:** Is one tool easier/harder to use (you may have to be the judge of this, given side-by-side code comparisons)

This page is also here to offer a bit of a translation guide for users of these R packages.

For transfer of DataFrame objects from pandas to R, one option is to use HDF5 files, see [External compatibility](#) for an example.

Quick reference

We'll start off with a quick reference guide pairing some common R operations using `dplyr` with pandas equivalents.

Querying, filtering, sampling

R	pandas
<code>dim(df)</code>	<code>df.shape</code>
<code>head(df)</code>	<code>df.head()</code>
<code>slice(df, 1:10)</code>	<code>df.iloc[:9]</code>
<code>filter(df, col1 == 1, col2 == 1)</code>	<code>df.query('col1 == 1 & col2 == 1')</code>
<code>df[df\$col1 == 1 & df\$col2 == 1,]</code>	<code>df[(df.col1 == 1) & (df.col2 == 1)]</code>
<code>select(df, col1, col2)</code>	<code>df[['col1', 'col2']]</code>
<code>select(df, col1:col3)</code>	<code>df.loc[:, 'col1':'col3']</code>
<code>select(df, -(col1:col3))</code>	<code>df.drop(cols_to_drop, axis=1) but see¹</code>
<code>distinct(select(df, col1))</code>	<code>df[['col1']].drop_duplicates()</code>
<code>distinct(select(df, col1, col2))</code>	<code>df[['col1', 'col2']].drop_duplicates()</code>
<code>sample_n(df, 10)</code>	<code>df.sample(n=10)</code>
<code>sample_frac(df, 0.01)</code>	<code>df.sample(frac=0.01)</code>

Sorting

R	pandas
<code>arrange(df, col1, col2)</code>	<code>df.sort_values(['col1', 'col2'])</code>
<code>arrange(df, desc(col1))</code>	<code>df.sort_values('col1', ascending=False)</code>

Transforming

R	pandas
<code>select(df, col_one = col1)</code>	<code>df.rename(columns={'col1': 'col_one'})['col_one']</code>
<code>rename(df, col_one = col1)</code>	<code>df.rename(columns={'col1': 'col_one'})</code>
<code>mutate(df, c=a-b)</code>	<code>df.assign(c=df['a']-df['b'])</code>

¹ R's shorthand for a subrange of columns (`select(df, col1:col3)`) can be approached cleanly in pandas, if you have the list of columns, for example `df[cols[1:3]]` or `df.drop(cols[1:3])`, but doing this by column name is a bit messy.

Grouping and summarizing

R	pandas
summary(df)	df.describe()
gdf <- group_by(df, col1)	gdf = df.groupby('col1')
summarise(gdf, avg=mean(col1, na.rm=TRUE))	df.groupby('col1').agg({'col1': 'mean'})
summarise(gdf, total=sum(col1))	df.groupby('col1').sum()

Base R

Slicing with R's c

R makes it easy to access `data.frame` columns by name

```
df <- data.frame(a=rnorm(5), b=rnorm(5), c=rnorm(5), d=rnorm(5), e=rnorm(5))
df[, c("a", "c", "e")]
```

or by integer location

```
df <- data.frame(matrix(rnorm(1000), ncol=100))
df[, c(1:10, 25:30, 40, 50:100)]
```

Selecting multiple columns by name in pandas is straightforward

```
In [1]: df = pd.DataFrame(np.random.randn(10, 3), columns=list("abc"))
```

```
In [2]: df[["a", "c"]]
```

```
Out[2]:
```

	a	c
0	0.469112	-1.509059
1	-1.135632	-0.173215
2	0.119209	-0.861849
3	-2.104569	1.071804
4	0.721555	-1.039575
5	0.271860	0.567020
6	0.276232	-0.673690
7	0.113648	0.524988
8	0.404705	-1.715002
9	-1.039268	-1.157892

```
In [3]: df.loc[:, ["a", "c"]]
```

```
Out[3]:
```

	a	c
0	0.469112	-1.509059
1	-1.135632	-0.173215
2	0.119209	-0.861849
3	-2.104569	1.071804
4	0.721555	-1.039575
5	0.271860	0.567020
6	0.276232	-0.673690
7	0.113648	0.524988

(continues on next page)

(continued from previous page)

```
8  0.404705 -1.715002
9 -1.039268 -1.157892
```

Selecting multiple noncontiguous columns by integer location can be achieved with a combination of the `iloc` indexer attribute and `numpy.r_`.

```
In [4]: named = list("abcdefg")
```

```
In [5]: n = 30
```

```
In [6]: columns = named + np.arange(len(named), n).tolist()
```

```
In [7]: df = pd.DataFrame(np.random.randn(n, n), columns=columns)
```

```
In [8]: df.iloc[:, np.r_[10, 24:30]]
```

```
Out[8]:
```

	a	b	c	d	e	f	...	24	25
0	-1.344312	0.844885	1.075770	-0.109050	1.643563	-1.469388	...	-1.170299	-0.226169
1	-0.076467	-1.187678	1.130127	-1.436737	-1.413681	1.607920	...	0.959726	-1.110336
2	0.176444	0.403310	-0.154951	0.301624	-2.179861	-1.369849	...	0.084844	0.432390
3	0.132885	-0.023688	2.410179	1.450520	0.206053	-0.251905	...	-2.484478	-0.281461
4	1.474071	-0.064034	-1.282782	0.781836	-1.071357	0.441153	...	-1.197071	-1.066969
...
25	1.492125	-0.068190	0.681456	1.221829	-0.434352	1.204815	...	1.944517	0.042344
26	0.725238	0.624607	-0.141185	-0.143948	-0.328162	2.095086	...	-0.846188	1.190624

	-0.332872	-2.013086	-1.602549	0.333109					

```
[30 rows x 16 columns]
```

aggregate

In R you may want to split data into subsets and compute the mean for each. Using a data.frame called `df` and splitting it into groups `by1` and `by2`:

```
df <- data.frame(
  v1 = c(1,3,5,7,8,3,5,NA,4,5,7,9),
  v2 = c(11,33,55,77,88,33,55,NA,44,55,77,99),
  by1 = c("red", "blue", 1, 2, NA, "big", 1, 2, "red", 1, NA, 12),
  by2 = c("wet", "dry", 99, 95, NA, "damp", 95, 99, "red", 99, NA, NA))
aggregate(x=df[, c("v1", "v2")], by=list(mydf2$by1, mydf2$by2), FUN = mean)
```

The `groupby()` method is similar to base R `aggregate` function.

```
In [9]: df = pd.DataFrame(
    {
        "v1": [1, 3, 5, 7, 8, 3, 5, np.nan, 4, 5, 7, 9],
        "v2": [11, 33, 55, 77, 88, 33, 55, np.nan, 44, 55, 77, 99],
        "by1": ["red", "blue", 1, 2, np.nan, "big", 1, 2, "red", 1, np.nan, 12],
        "by2": [
            "wet",
            "dry",
            99,
            95,
            np.nan,
            "damp",
            95,
            99,
            "red",
            99,
            np.nan,
            np.nan,
        ],
    }
)
In [10]: g = df.groupby(["by1", "by2"])
In [11]: g[["v1", "v2"]].mean()
Out[11]:
      v1      v2
by1  by2
1    95    5.0  55.0
      99    5.0  55.0
2    95    7.0  77.0
      99    NaN   NaN
big  damp   3.0  33.0
blue dry    3.0  33.0
red  red    4.0  44.0
wet   wet   1.0  11.0
```

For more details and examples see [the `groupby` documentation](#).

match / %in%

A common way to select data in R is using `%in%` which is defined using the function `match`. The operator `%in%` is used to return a logical vector indicating if there is a match or not:

```
s <- 0:4
s %in% c(2,4)
```

The `isin()` method is similar to R `%in%` operator:

```
In [12]: s = pd.Series(np.arange(5), dtype=np.float32)
```

```
In [13]: s.isin([2, 4])
```

```
Out[13]:
```

```
0    False
1    False
2     True
3    False
4     True
dtype: bool
```

The `match` function returns a vector of the positions of matches of its first argument in its second:

```
s <- 0:4
match(s, c(2,4))
```

For more details and examples see *the reshaping documentation*.

tapply

`tapply` is similar to `aggregate`, but data can be in a ragged array, since the subclass sizes are possibly irregular. Using a data.frame called `baseball`, and retrieving information based on the array `team`:

```
baseball <-
  data.frame(team = gl(5, 5,
                       labels = paste("Team", LETTERS[1:5])),
             player = sample(letters, 25),
             batting.average = runif(25, .200, .400))

tapply(baseball$batting.average, baseball.example$team,
       max)
```

In pandas we may use `pivot_table()` method to handle this:

```
In [14]: import random
```

```
In [15]: import string
```

```
In [16]: baseball = pd.DataFrame(
.....      {
.....        "team": ["team %d" % (x + 1) for x in range(5)] * 5,
.....        "player": random.sample(string.ascii_lowercase, 25),
.....        "batting avg": np.random.uniform(.200, .400, 25),
```

(continues on next page)

(continued from previous page)

```
....:     }
....: )
....:
```

In [17]: baseball.pivot_table(values="batting avg", columns="team", aggfunc=np.max)
Out[17]:

team	team 1	team 2	team 3	team 4	team 5
batting avg	0.352134	0.295327	0.397191	0.394457	0.396194

For more details and examples see *the reshaping documentation*.

subset

The `query()` method is similar to the base R `subset` function. In R you might want to get the rows of a `data.frame` where one column's values are less than another column's values:

```
df <- data.frame(a=rnorm(10), b=rnorm(10))
subset(df, a <= b)
df[df$a <= df$b,] # note the comma
```

In pandas, there are a few ways to perform subsetting. You can use `query()` or pass an expression as if it were an index/slice as well as standard boolean indexing:

In [18]: df = pd.DataFrame({"a": np.random.randn(10), "b": np.random.randn(10)})

In [19]: df.query("a <= b")
Out[19]:

	a	b
1	0.174950	0.552887
2	-0.023167	0.148084
3	-0.495291	-0.300218
4	-0.860736	0.197378
5	-1.134146	1.720780
7	-0.290098	0.083515
8	0.238636	0.946550

In [20]: df[df["a"] <= df["b"]]

Out[20]:

	a	b
1	0.174950	0.552887
2	-0.023167	0.148084
3	-0.495291	-0.300218
4	-0.860736	0.197378
5	-1.134146	1.720780
7	-0.290098	0.083515
8	0.238636	0.946550

In [21]: df.loc[df["a"] <= df["b"]]

Out[21]:

	a	b
1	0.174950	0.552887

(continues on next page)

(continued from previous page)

```
2 -0.023167  0.148084
3 -0.495291 -0.300218
4 -0.860736  0.197378
5 -1.134146  1.720780
7 -0.290098  0.083515
8  0.238636  0.946550
```

For more details and examples see [the query documentation](#).

with

An expression using a data.frame called df in R with the columns a and b would be evaluated using `with` like so:

```
df <- data.frame(a=rnorm(10), b=rnorm(10))
with(df, a + b)
df$a + df$b  # same as the previous expression
```

In pandas the equivalent expression, using the `eval()` method, would be:

```
In [22]: df = pd.DataFrame({"a": np.random.randn(10), "b": np.random.randn(10)})
```

```
In [23]: df.eval("a + b")
```

```
Out[23]:
```

```
0   -0.091430
1   -2.483890
2   -0.252728
3   -0.626444
4   -0.261740
5    2.149503
6   -0.332214
7    0.799331
8   -2.377245
9    2.104677
dtype: float64
```

```
In [24]: df["a"] + df["b"]  # same as the previous expression
```

```
Out[24]:
```

```
0   -0.091430
1   -2.483890
2   -0.252728
3   -0.626444
4   -0.261740
5    2.149503
6   -0.332214
7    0.799331
8   -2.377245
9    2.104677
dtype: float64
```

In certain cases `eval()` will be much faster than evaluation in pure Python. For more details and examples see [the eval documentation](#).

plyr

plyr is an R library for the split-apply-combine strategy for data analysis. The functions revolve around three data structures in R, a for arrays, l for lists, and d for data.frame. The table below shows how these data structures could be mapped in Python.

R	Python
array	list
lists	dictionary or list of objects
data.frame	dataframe

ddply

An expression using a data.frame called df in R where you want to summarize x by month:

```
require(plyr)
df <- data.frame(
  x = runif(120, 1, 168),
  y = runif(120, 7, 334),
  z = runif(120, 1.7, 20.7),
  month = rep(c(5,6,7,8),30),
  week = sample(1:4, 120, TRUE)
)

ddply(df, .(month, week), summarize,
      mean = round(mean(x), 2),
      sd = round(sd(x), 2))
```

In pandas the equivalent expression, using the `groupby()` method, would be:

```
In [25]: df = pd.DataFrame(
    ....:
    ....:     "x": np.random.uniform(1.0, 168.0, 120),
    ....:     "y": np.random.uniform(7.0, 334.0, 120),
    ....:     "z": np.random.uniform(1.7, 20.7, 120),
    ....:     "month": [5, 6, 7, 8] * 30,
    ....:     "week": np.random.randint(1, 4, 120),
    ....: )
    ....:
```

```
In [26]: grouped = df.groupby(["month", "week"])
```

```
In [27]: grouped["x"].agg([np.mean, np.std])
```

```
Out[27]:
           mean        std
month week
5      1    63.653367  40.601965
      2    78.126605  53.342400
      3   92.091886  57.630110
6      1    81.747070  54.339218
      2   70.971205  54.687287
```

(continues on next page)

(continued from previous page)

	3	100.968344	54.010081
7	1	61.576332	38.844274
	2	61.733510	48.209013
	3	71.688795	37.595638
8	1	62.741922	34.618153
	2	91.774627	49.790202
	3	73.936856	60.773900

For more details and examples see *the groupby documentation*.

reshape / reshape2

meltarray

An expression using a 3 dimensional array called a in R where you want to melt it into a data.frame:

```
a <- array(c(1:23, NA), c(2,3,4))
data.frame(melt(a))
```

In Python, since a is a list, you can simply use list comprehension.

```
In [28]: a = np.array(list(range(1, 24)) + [np.NAN]).reshape(2, 3, 4)
In [29]: pd.DataFrame([tuple(list(x) + [val]) for x, val in np.ndenumerate(a)])
Out[29]:
   0   1   2   3
0   0   0   0   1.0
1   0   0   1   2.0
2   0   0   2   3.0
3   0   0   3   4.0
4   0   1   0   5.0
...
19  1   1   3   20.0
20  1   2   0   21.0
21  1   2   1   22.0
22  1   2   2   23.0
23  1   2   3   NaN

[24 rows x 4 columns]
```

meltlist

An expression using a list called a in R where you want to melt it into a data.frame:

```
a <- as.list(c(1:4, NA))
data.frame(melt(a))
```

In Python, this list would be a list of tuples, so `DataFrame()` method would convert it to a dataframe as required.

```
In [30]: a = list(enumerate(list(range(1, 5)) + [np.NAN]))
```

```
In [31]: pd.DataFrame(a)
```

```
Out[31]:
```

	0	1
0	0	1.0
1	1	2.0
2	2	3.0
3	3	4.0
4	4	NaN

For more details and examples see *the Into to Data Structures documentation*.

meltdf

An expression using a data.frame called cheese in R where you want to reshape the data.frame:

```
cheese <- data.frame(
  first = c('John', 'Mary'),
  last = c('Doe', 'Bo'),
  height = c(5.5, 6.0),
  weight = c(130, 150)
)
melt(cheese, id=c("first", "last"))
```

In Python, the `melt()` method is the R equivalent:

```
In [32]: cheese = pd.DataFrame(
    ....:     {
    ....:         "first": ["John", "Mary"],
    ....:         "last": ["Doe", "Bo"],
    ....:         "height": [5.5, 6.0],
    ....:         "weight": [130, 150],
    ....:     }
    ....: )
```

```
In [33]: pd.melt(cheese, id_vars=["first", "last"])
```

```
Out[33]:
```

	first	last	variable	value
0	John	Doe	height	5.5
1	Mary	Bo	height	6.0
2	John	Doe	weight	130.0
3	Mary	Bo	weight	150.0

```
In [34]: cheese.set_index(["first", "last"]).stack() # alternative way
```

```
Out[34]:
```

	first	last		
John	Doe	height	5.5	
		weight	130.0	
Mary	Bo	height	6.0	
		weight	150.0	

(continues on next page)

(continued from previous page)

dtype: float64

For more details and examples see *the reshaping documentation*.

cast

In R `acast` is an expression using a `data.frame` called `df` in R to cast into a higher dimensional array:

```
df <- data.frame(
  x = runif(12, 1, 168),
  y = runif(12, 7, 334),
  z = runif(12, 1.7, 20.7),
  month = rep(c(5,6,7),4),
  week = rep(c(1,2), 6)
)

mdf <- melt(df, id=c("month", "week"))
acast(mdf, week ~ month ~ variable, mean)
```

In Python the best way is to make use of `pivot_table()`:

```
In [35]: df = pd.DataFrame(
    .....
    {
        "x": np.random.uniform(1.0, 168.0, 12),
        "y": np.random.uniform(7.0, 334.0, 12),
        "z": np.random.uniform(1.7, 20.7, 12),
        "month": [5, 6, 7] * 4,
        "week": [1, 2] * 6,
    }
.....
```

```
In [36]: mdf = pd.melt(df, id_vars=["month", "week"])
```

```
In [37]: pd.pivot_table(
    mdf,
    values="value",
    index=["variable", "week"],
    columns=["month"],
    aggfunc=np.mean,
.....
```

Out[37]:

month	5	6	7	
variable	week			
x	1	93.888747	98.762034	55.219673
	2	94.391427	38.112932	83.942781
y	1	94.306912	279.454811	227.840449
	2	87.392662	193.028166	173.899260
z	1	11.016009	10.079307	16.170549
	2	8.476111	17.638509	19.003494

Similarly for dcast which uses a data.frame called df in R to aggregate information based on Animal and FeedType:

```
df <- data.frame(
  Animal = c('Animal1', 'Animal2', 'Animal3', 'Animal2', 'Animal1',
            'Animal2', 'Animal3'),
  FeedType = c('A', 'B', 'A', 'A', 'B', 'B', 'A'),
  Amount = c(10, 7, 4, 2, 5, 6, 2)
)

dcast(df, Animal ~ FeedType, sum, fill=NaN)
# Alternative method using base R
with(df, tapply(Amount, list(Animal, FeedType), sum))
```

Python can approach this in two different ways. Firstly, similar to above using `pivot_table()`:

```
In [38]: df = pd.DataFrame(
    {
        "Animal": [
            "Animal1",
            "Animal2",
            "Animal3",
            "Animal2",
            "Animal1",
            "Animal2",
            "Animal3",
        ],
        "FeedType": ["A", "B", "A", "A", "B", "B", "A"],
        "Amount": [10, 7, 4, 2, 5, 6, 2],
    }
)

In [39]: df.pivot_table(values="Amount", index="Animal", columns="FeedType", aggfunc="sum")
```

```
Out[39]:
FeedType      A      B
Animal
Animal1     10.0    5.0
Animal2      2.0   13.0
Animal3      6.0    NaN
```

The second approach is to use the `groupby()` method:

```
In [40]: df.groupby(["Animal", "FeedType"])["Amount"].sum()
Out[40]:
Animal  FeedType
Animal1  A          10
           B          5
Animal2  A          2
           B         13
Animal3  A          6
Name: Amount, dtype: int64
```

For more details and examples see [the reshaping documentation](#) or [the groupby documentation](#).

factor

pandas has a data type for categorical data.

```
cut(c(1,2,3,4,5,6), 3)
factor(c(1,2,3,2,2,3))
```

In pandas this is accomplished with `pd.cut` and `astype("category")`:

```
In [41]: pd.cut(pd.Series([1, 2, 3, 4, 5, 6]), 3)
Out[41]:
0      (0.995, 2.667]
1      (0.995, 2.667]
2      (2.667, 4.333]
3      (2.667, 4.333]
4      (4.333, 6.0]
5      (4.333, 6.0]
dtype: category
Categories (3, interval[float64, right]): [(0.995, 2.667] < (2.667, 4.333] < (4.333, 6.
˓→0]]
```

```
In [42]: pd.Series([1, 2, 3, 2, 2, 3]).astype("category")
Out[42]:
0    1
1    2
2    3
3    2
4    2
5    3
dtype: category
Categories (3, int64): [1, 2, 3]
```

For more details and examples see [categorical introduction](#) and the [API documentation](#). There is also a documentation regarding the [differences to R's factor](#).

Comparison with SQL

Since many potential pandas users have some familiarity with [SQL](#), this page is meant to provide some examples of how various SQL operations would be performed using pandas.

If you're new to pandas, you might want to first read through [10 Minutes to pandas](#) to familiarize yourself with the library.

As is customary, we import pandas and NumPy as follows:

```
In [1]: import pandas as pd
In [2]: import numpy as np
```

Most of the examples will utilize the `tips` dataset found within pandas tests. We'll read the data into a DataFrame called `tips` and assume we have a database table of the same name and structure.

```
In [3]: url = (
...:     "https://raw.github.com/pandas-dev"
```

(continues on next page)

(continued from previous page)

```

...:     "/pandas/main/pandas/tests/io/data/csv/tips.csv"
...: )
...:

In [4]: tips = pd.read_csv(url)

In [5]: tips
Out[5]:
   total_bill  tip    sex smoker  day   time  size
0      16.99  1.01  Female    No  Sun  Dinner     2
1      10.34  1.66    Male    No  Sun  Dinner     3
2      21.01  3.50    Male    No  Sun  Dinner     3
3      23.68  3.31    Male    No  Sun  Dinner     2
4      24.59  3.61  Female    No  Sun  Dinner     4
..        ...
239     29.03  5.92    Male    No  Sat  Dinner     3
240     27.18  2.00  Female   Yes  Sat  Dinner     2
241     22.67  2.00    Male   Yes  Sat  Dinner     2
242     17.82  1.75    Male    No  Sat  Dinner     2
243     18.78  3.00  Female    No Thur  Dinner     2

[244 rows x 7 columns]

```

Copies vs. in place operations

Most pandas operations return copies of the Series/DataFrame. To make the changes “stick”, you’ll need to either assign to a new variable:

```
sorted_df = df.sort_values("col1")
```

or overwrite the original one:

```
df = df.sort_values("col1")
```

Note: You will see an `inplace=True` keyword argument available for some methods:

```
df.sort_values("col1", inplace=True)
```

Its use is discouraged. *More information.*

SELECT

In SQL, selection is done using a comma-separated list of columns you'd like to select (or a * to select all columns):

```
SELECT total_bill, tip, smoker, time  
FROM tips;
```

With pandas, column selection is done by passing a list of column names to your DataFrame:

```
In [6]: tips[["total_bill", "tip", "smoker", "time"]]  
Out[6]:  

|     | total_bill | tip  | smoker | time   |
|-----|------------|------|--------|--------|
| 0   | 16.99      | 1.01 | No     | Dinner |
| 1   | 10.34      | 1.66 | No     | Dinner |
| 2   | 21.01      | 3.50 | No     | Dinner |
| 3   | 23.68      | 3.31 | No     | Dinner |
| 4   | 24.59      | 3.61 | No     | Dinner |
| ..  | ...        | ...  | ...    | ...    |
| 239 | 29.03      | 5.92 | No     | Dinner |
| 240 | 27.18      | 2.00 | Yes    | Dinner |
| 241 | 22.67      | 2.00 | Yes    | Dinner |
| 242 | 17.82      | 1.75 | No     | Dinner |
| 243 | 18.78      | 3.00 | No     | Dinner |

  
[244 rows x 4 columns]
```

Calling the DataFrame without the list of column names would display all columns (akin to SQL's *).

In SQL, you can add a calculated column:

```
SELECT *, tip/total_bill as tip_rate  
FROM tips;
```

With pandas, you can use the `DataFrame.assign()` method of a DataFrame to append a new column:

```
In [7]: tips.assign(tip_rate=tips["tip"] / tips["total_bill"])  
Out[7]:  

|     | total_bill | tip  | sex    | smoker | day  | time   | size | tip_rate |
|-----|------------|------|--------|--------|------|--------|------|----------|
| 0   | 16.99      | 1.01 | Female | No     | Sun  | Dinner | 2    | 0.059447 |
| 1   | 10.34      | 1.66 | Male   | No     | Sun  | Dinner | 3    | 0.160542 |
| 2   | 21.01      | 3.50 | Male   | No     | Sun  | Dinner | 3    | 0.166587 |
| 3   | 23.68      | 3.31 | Male   | No     | Sun  | Dinner | 2    | 0.139780 |
| 4   | 24.59      | 3.61 | Female | No     | Sun  | Dinner | 4    | 0.146808 |
| ..  | ...        | ...  | ...    | ...    | ...  | ...    | ...  | ...      |
| 239 | 29.03      | 5.92 | Male   | No     | Sat  | Dinner | 3    | 0.203927 |
| 240 | 27.18      | 2.00 | Female | Yes    | Sat  | Dinner | 2    | 0.073584 |
| 241 | 22.67      | 2.00 | Male   | Yes    | Sat  | Dinner | 2    | 0.088222 |
| 242 | 17.82      | 1.75 | Male   | No     | Sat  | Dinner | 2    | 0.098204 |
| 243 | 18.78      | 3.00 | Female | No     | Thur | Dinner | 2    | 0.159744 |

  
[244 rows x 8 columns]
```

WHERE

Filtering in SQL is done via a WHERE clause.

```
SELECT *
FROM tips
WHERE time = 'Dinner';
```

DataFrames can be filtered in multiple ways; the most intuitive of which is using *boolean indexing*.

```
In [8]: tips[tips["total_bill"] > 10]
Out[8]:
   total_bill  tip    sex smoker  day    time  size
0      16.99  1.01  Female    No  Sun  Dinner    2
1      10.34  1.66    Male    No  Sun  Dinner    3
2      21.01  3.50    Male    No  Sun  Dinner    3
3      23.68  3.31    Male    No  Sun  Dinner    2
4      24.59  3.61  Female    No  Sun  Dinner    4
...
239     29.03  5.92    Male    No  Sat  Dinner    3

241     22.67  2.00    Male   Yes  Sat  Dinner    2
242     17.82  1.75    Male    No  Sat  Dinner    2
243     18.78  3.00  Female    No Thur  Dinner    2

[227 rows x 7 columns]
```

The above statement is simply passing a Series of True/False objects to the DataFrame, returning all rows with True.

```
In [9]: is_dinner = tips["time"] == "Dinner"
```

```
In [10]: is_dinner
```

```
Out[10]:
```

```
0      True
1      True
2      True
3      True
4      True
...
239     True
240     True
241     True
242     True
243     True
Name: time, Length: 244, dtype: bool
```

```
In [11]: is_dinner.value_counts()
```

```
Out[11]:
```

```
True    176
False   68

44	30.40	5.60	Male	No	Sun	Dinner	4
47	32.40	6.00	Male	No	Sun	Dinner	4
52	34.81	5.20	Female	No	Sun	Dinner	4
59	48.27	6.73	Male	No	Sat	Dinner	4
116	29.93	5.07	Male	No	Sun	Dinner	4
155	29.85	5.14	Female	No	Sun	Dinner	5
170	50.81	10.00	Male	Yes	Sat	Dinner	3
172	7.25	5.15	Male	Yes	Sun	Dinner	2
181	23.33	5.65	Male	Yes	Sun	Dinner	2
183	23.17	6.50	Male	Yes	Sun	Dinner	4
211	25.89	5.16	Male	Yes	Sat	Dinner	4
212	48.33	9.00	Male	No	Sat	Dinner	4
214	28.17	6.50	Female	Yes	Sat	Dinner	3
239	29.03	5.92	Male	No	Sat	Dinner	3

Tips by parties of at least 5 diners OR bill total was more than \$45:

```
SELECT *
FROM tips
WHERE size >= 5 OR total_bill > 45;
```

In [14]: tips[(tips["size"] >= 5) | (tips["total_bill"] > 45)]**Out[14]:**

(continues on next page)

(continued from previous page)

	total_bill	tip	sex	smoker	day	time	size
59	48.27	6.73	Male	No	Sat	Dinner	4
125	29.80	4.20	Female	No	Thur	Lunch	6
141	34.30	6.70	Male	No	Thur	Lunch	6
142	41.19	5.00	Male	No	Thur	Lunch	5
143	27.05	5.00	Female	No	Thur	Lunch	6
155	29.85	5.14	Female	No	Sun	Dinner	5
156	48.17	5.00	Male	No	Sun	Dinner	6
170	50.81	10.00	Male	Yes	Sat	Dinner	3
182	45.35	3.50	Male	Yes	Sun	Dinner	3
185	20.69	5.00	Male	No	Sun	Dinner	5
187	30.46	2.00	Male	Yes	Sun	Dinner	5
212	48.33	9.00	Male	No	Sat	Dinner	4
216	28.15	3.00	Male	Yes	Sat	Dinner	5

NULL checking is done using the `notna()` and `isna()` methods.

```
In [15]: frame = pd.DataFrame(
....:     {"col1": ["A", "B", np.NaN, "C", "D"], "col2": ["F", np.NaN, "G", "H", "I"]}
....: )
....:
```

```
In [16]: frame
Out[16]:
   col1  col2
0      A    F
1      B  NaN
2    NaN    G
3      C    H
4      D    I
```

Assume we have a table of the same structure as our DataFrame above. We can see only the records where `col2` IS NULL with the following query:

```
SELECT *
FROM frame
WHERE col2 IS NULL;
```

```
In [17]: frame[frame["col2"].isna()]
Out[17]:
   col1  col2
1      B  NaN
```

Getting items where `col1` IS NOT NULL can be done with `notna()`.

```
SELECT *
FROM frame
WHERE col1 IS NOT NULL;
```

```
In [18]: frame[frame["col1"].notna()]
Out[18]:
   col1  col2
```

(continues on next page)

(continued from previous page)

0	A	F
1	B	NaN
3	C	H
4	D	I

GROUP BY

In pandas, SQL's GROUP BY operations are performed using the similarly named `groupby()` method. `groupby()` typically refers to a process where we'd like to split a dataset into groups, apply some function (typically aggregation), and then combine the groups together.

A common SQL operation would be getting the count of records in each group throughout a dataset. For instance, a query getting us the number of tips left by sex:

```
SELECT sex, count(*)
FROM tips
GROUP BY sex;
/*
Female      87
Male       157
*/
```

The pandas equivalent would be:

```
In [19]: tips.groupby("sex").size()
Out[19]:
sex
Female      87
Male       157
dtype: int64
```

Notice that in the pandas code we used `size()` and not `count()`. This is because `count()` applies the function to each column, returning the number of NOT NULL records within each.

```
In [20]: tips.groupby("sex").count()
Out[20]:
      total_bill  tip  smoker  day  time  size
sex
Female          87    87      87    87     87    87
Male           157   157     157   157    157   157
```

Alternatively, we could have applied the `count()` method to an individual column:

```
In [21]: tips.groupby("sex")["total_bill"].count()
Out[21]:
sex
Female      87
Male       157
Name: total_bill, dtype: int64
```

Multiple functions can also be applied at once. For instance, say we'd like to see how tip amount differs by day of the week - `agg()` allows you to pass a dictionary to your grouped DataFrame, indicating which functions to apply to specific columns.

```
SELECT day, AVG(tip), COUNT(*)
FROM tips
GROUP BY day;
/*
Fri    2.734737  19
Sat    2.993103  87
Sun    3.255132  76
Thu    2.771452  62
*/
```

In [22]: `tips.groupby("day").agg({"tip": np.mean, "day": np.size})`

Out[22]:

	tip	day
day		
Fri	2.734737	19
Sat	2.993103	87
Sun	3.255132	76
Thur	2.771452	62

Grouping by more than one column is done by passing a list of columns to the `groupby()` method.

```
SELECT smoker, day, COUNT(*), AVG(tip)
FROM tips
GROUP BY smoker, day;
/*
smoker  day
No      Fri      4  2.812500
        Sat      45 3.102889
        Sun      57 3.167895
        Thu      45 2.673778
Yes     Fri      15 2.714000
        Sat      42 2.875476
        Sun      19 3.516842
        Thur     17 3.030000
*/
```

In [23]: `tips.groupby(["smoker", "day"]).agg({"tip": [np.size, np.mean]})`

Out[23]:

		tip	
		size	mean
smoker	day		
No	Fri	4	2.812500
	Sat	45	3.102889
	Sun	57	3.167895
	Thur	45	2.673778
Yes	Fri	15	2.714000
	Sat	42	2.875476
	Sun	19	3.516842
	Thur	17	3.030000

JOIN

JOINS can be performed with `join()` or `merge()`. By default, `join()` will join the DataFrames on their indices. Each method has parameters allowing you to specify the type of join to perform (LEFT, RIGHT, INNER, FULL) or the columns to join on (column names or indices).

Warning: If both key columns contain rows where the key is a null value, those rows will be matched against each other. This is different from usual SQL join behaviour and can lead to unexpected results.

```
In [24]: df1 = pd.DataFrame({"key": ["A", "B", "C", "D"], "value": np.random.randn(4)})
```

```
In [25]: df2 = pd.DataFrame({"key": ["B", "D", "D", "E"], "value": np.random.randn(4)})
```

Assume we have two database tables of the same name and structure as our DataFrames.

Now let's go over the various types of JOINS.

INNER JOIN

```
SELECT *
FROM df1
INNER JOIN df2
    ON df1.key = df2.key;
```

```
# merge performs an INNER JOIN by default
```

```
In [26]: pd.merge(df1, df2, on="key")
```

Out[26]:

	key	value_x	value_y
0	B	-0.282863	1.212112
1	D	-1.135632	-0.173215
2	D	-1.135632	0.119209

`merge()` also offers parameters for cases when you'd like to join one DataFrame's column with another DataFrame's index.

```
In [27]: indexed_df2 = df2.set_index("key")
```

```
In [28]: pd.merge(df1, indexed_df2, left_on="key", right_index=True)
```

Out[28]:

	key	value_x	value_y
1	B	-0.282863	1.212112
3	D	-1.135632	-0.173215
3	D	-1.135632	0.119209

LEFT OUTER JOIN

Show all records from df1.

```
SELECT *
FROM df1
LEFT OUTER JOIN df2
ON df1.key = df2.key;
```

In [29]: pd.merge(df1, df2, on="key", how="left")

Out[29]:

	key	value_x	value_y
0	A	0.469112	NaN
1	B	-0.282863	1.212112
2	C	-1.509059	NaN
3	D	-1.135632	-0.173215
4	D	-1.135632	0.119209

RIGHT JOIN

Show all records from df2.

```
SELECT *
FROM df1
RIGHT OUTER JOIN df2
ON df1.key = df2.key;
```

In [30]: pd.merge(df1, df2, on="key", how="right")

Out[30]:

	key	value_x	value_y
0	B	-0.282863	1.212112
1	D	-1.135632	-0.173215
2	D	-1.135632	0.119209
3	E	NaN	-1.044236

FULL JOIN

pandas also allows for FULL JOINS, which display both sides of the dataset, whether or not the joined columns find a match. As of writing, FULL JOINS are not supported in all RDBMS (MySQL).

Show all records from both tables.

```
SELECT *
FROM df1
FULL OUTER JOIN df2
ON df1.key = df2.key;
```

In [31]: pd.merge(df1, df2, on="key", how="outer")

Out[31]:

	key	value_x	value_y
--	-----	---------	---------

(continues on next page)

(continued from previous page)

```
0   A  0.469112      NaN
1   B -0.282863  1.212112
2   C -1.509059      NaN
3   D -1.135632 -0.173215
4   D -1.135632  0.119209
5   E      NaN -1.044236
```

UNION

`UNION ALL` can be performed using `concat()`.

```
In [32]: df1 = pd.DataFrame(
....:     {"city": ["Chicago", "San Francisco", "New York City"], "rank": range(1, 4)}
....:
....:

In [33]: df2 = pd.DataFrame(
....:     {"city": ["Chicago", "Boston", "Los Angeles"], "rank": [1, 4, 5]}
....:
....:
```

```
SELECT city, rank
FROM df1
UNION ALL
SELECT city, rank
FROM df2;
/*
    city  rank
    Chicago    1
    San Francisco    2
    New York City    3
    Chicago    1
    Boston    4
    Los Angeles    5
*/
```

```
In [34]: pd.concat([df1, df2])
Out[34]:
        city  rank
0      Chicago    1
1  San Francisco    2
2  New York City    3
0      Chicago    1
1      Boston    4
2  Los Angeles    5
```

SQL's `UNION` is similar to `UNION ALL`, however `UNION` will remove duplicate rows.

```
SELECT city, rank
FROM df1
```

(continues on next page)

(continued from previous page)

```
UNION
SELECT city, rank
FROM df2;
-- notice that there is only one Chicago record this time
/*
    city  rank
    Chicago      1
San Francisco      2
New York City      3
    Boston      4
    Los Angeles      5
*/
```

In pandas, you can use `concat()` in conjunction with `drop_duplicates()`.

In [35]: `pd.concat([df1, df2]).drop_duplicates()`

Out[35]:

	city	rank
0	Chicago	1
1	San Francisco	2
2	New York City	3
1	Boston	4
2	Los Angeles	5

LIMIT

```
SELECT * FROM tips
LIMIT 10;
```

In [36]: `tips.head(10)`

Out[36]:

	total_bill	tip	sex	smoker	day	time	size
0	16.99	1.01	Female	No	Sun	Dinner	2
1	10.34	1.66	Male	No	Sun	Dinner	3
2	21.01	3.50	Male	No	Sun	Dinner	3

the same using `rank(method='first')` function

```
In [39]: (
    ....:     tips.assign(
    ....:         rnk=tips.groupby(["day"])["total_bill"].rank(
    ....:             method="first", ascending=False
    ....:         )
    ....:     )
    ....:     .query("rnk < 3")
    ....:     .sort_values(["day", "rnk"])
    ....: )
    ....:

Out[39]:
   total_bill      tip      sex smoker  day     time    size  rnk
95      40.17    4.73    Male   Yes  Fri  Dinner     4  1.0
90      28.97    3.00    Male   Yes  Fri  Dinner     2  2.0
170     50.81   10.00    Male   Yes  Sat  Dinner     3  1.0
212     48.33    9.00    Male    No  Sat  Dinner     4  2.0
156     48.17    5.00    Male    No  Sun  Dinner     6  1.0
182     45.35    3.50    Male   Yes  Sun  Dinner     3  2.0
197     43.11    5.00  Female  Yes  Thur Lunch     4  1.0
142     41.19    5.00    Male    No  Thur Lunch     5  2.0
```

```
-- Oracle's RANK() analytic function
SELECT * FROM (
    SELECT
        t.*,
        RANK() OVER(PARTITION BY sex ORDER BY tip) AS rnk
    FROM tips t
    WHERE tip < 2
)
WHERE rnk < 3
ORDER BY sex, rnk;
```

Let's find tips with (`rank < 3`) per gender group for (`tips < 2`). Notice that when using `rank(method='min')` function `rnk_min` remains the same for the same `tip` (as Oracle's `RANK()` function)

```
In [40]: (
    ....:     tips[tips["tip"] < 2]
    ....:     .assign(rnk_min=tips.groupby(["sex"])["tip"].rank(method="min"))
    ....:     .query("rnk_min < 3")
    ....:     .sort_values(["sex", "rnk_min"])
    ....: )
    ....:

Out[40]:
```

(continues on next page)

(continued from previous page)

	total_bill	tip	sex	smoker	day	time	size	rnk_min
67	3.07	1.00	Female	Yes	Sat	Dinner	1	1.0
92	5.75	1.00	Female	Yes	Fri	Dinner	2	1.0
111	7.25	1.00	Female	No	Sat	Dinner	1	1.0
236	12.60	1.00	Male	Yes	Sat	Dinner	2	1.0
237	32.83	1.17	Male	Yes	Sat	Dinner	2	2.0

UPDATE

```
UPDATE tips
SET tip = tip*2
WHERE tip < 2;
```

```
In [41]: tips.loc[tips["tip"] < 2, "tip"] *= 2
```

DELETE

```
DELETE FROM tips
WHERE tip > 9;
```

In pandas we select the rows that should remain instead of deleting them:

```
In [42]: tips = tips.loc[tips["tip"] <= 9]
```

Comparison with spreadsheets

Since many potential pandas users have some familiarity with spreadsheet programs like [Excel](#), this page is meant to provide some examples of how various spreadsheet operations would be performed using pandas. This page will use terminology and link to documentation for Excel, but much will be the same/similar in [Google Sheets](#), [LibreOffice Calc](#), [Apple Numbers](#), and other Excel-compatible spreadsheet software.

If you're new to pandas, you might want to first read through [10 Minutes to pandas](#) to familiarize yourself with the library.

As is customary, we import pandas and NumPy as follows:

```
In [1]: import pandas as pd
```

```
In [2]: import numpy as np
```

Data structures

General terminology translation

pandas	Excel
DataFrame	worksheet
Series	column
Index	row headings
row	row
NaN	empty cell

DataFrame

A DataFrame in pandas is analogous to an Excel worksheet. While an Excel workbook can contain multiple worksheets, pandas DataFrames exist independently.

Series

A Series is the data structure that represents one column of a DataFrame. Working with a Series is analogous to referencing a column of a spreadsheet.

Index

Every DataFrame and Series has an Index, which are labels on the rows of the data. In pandas, if no index is specified, a RangeIndex is used by default (first row = 0, second row = 1, and so on), analogous to row headings/numbers in spreadsheets.

In pandas, indexes can be set to one (or multiple) unique values, which is like having a column that is used as the row identifier in a worksheet. Unlike most spreadsheets, these Index values can actually be used to reference the rows. (Note that this can be done in Excel with structured references.) For example, in spreadsheets, you would reference the first row as A1:Z1, while in pandas you could use populations.loc['Chicago'].

Index values are also persistent, so if you re-order the rows in a DataFrame, the label for a particular row don't change.

See the [indexing documentation](#) for much more on how to use an Index effectively.

Copies vs. in place operations

Most pandas operations return copies of the Series/DataFrame. To make the changes “stick”, you’ll need to either assign to a new variable:

```
sorted_df = df.sort_values("col1")
```

or overwrite the original one:

```
df = df.sort_values("col1")
```

Note: You will see an `inplace=True` keyword argument available for some methods:

```
df.sort_values("col1", inplace=True)
```

Its use is discouraged. [More information.](#)

Data input / output

Constructing a DataFrame from values

In a spreadsheet, values can be typed directly into cells.

A pandas DataFrame can be constructed in many different ways, but for a small number of values, it is often convenient to specify it as a Python dictionary, where the keys are the column names and the values are the data.

```
In [3]: df = pd.DataFrame({"x": [1, 3, 5], "y": [2, 4, 6]})
```

```
In [4]: df
```

```
Out[4]:
```

```
   x  y
0  1  2
1  3  4
2  5  6
```

Reading external data

Both Excel and *pandas* can import data from various sources in various formats.

CSV

Let's load and display the `tips` dataset from the pandas tests, which is a CSV file. In Excel, you would download and then [open the CSV](#). In pandas, you pass the URL or local path of the CSV file to `read_csv()`:

```
In [5]: url = (
...:     "https://raw.github.com/pandas-dev"
...:     "/pandas/main/pandas/tests/io/data/csv/tips.csv"
...: )
...:
```

```
In [6]: tips = pd.read_csv(url)
```

```
In [7]: tips
```

```
Out[7]:
```

	total_bill	tip	sex	smoker	day	time	size
0	16.99	1.01	Female	No	Sun	Dinner	2
1	10.34	1.66	Male	No	Sun	Dinner	3
2	21.01	3.50	Male	No	Sun	Dinner	3
3	23.68	3.31	Male	No	Sun	Dinner	2
4	24.59	3.61	Female	No	Sun	Dinner	4
..
239	29.03	5.92	Male	No	Sat	Dinner	3

(continues on next page)

(continued from previous page)

240	27.18	2.00	Female	Yes	Sat	Dinner	2
241	22.67	2.00	Male	Yes	Sat	Dinner	2
242	17.82	1.75	Male	No	Sat	Dinner	2
243	18.78	3.00	Female	No	Thur	Dinner	2

[244 rows x 7 columns]

Like Excel's Text Import Wizard, `read_csv` can take a number of parameters to specify how the data should be parsed. For example, if the data was instead tab delimited, and did not have column names, the pandas command would be:

```
tips = pd.read_csv("tips.csv", sep="\t", header=None)

# alternatively, read_table is an alias to read_csv with tab delimiter
tips = pd.read_table("tips.csv", header=None)
```

Excel files

Excel opens various Excel file formats by double-clicking them, or using the Open menu. In pandas, you use *special methods for reading and writing from/to Excel files*.

Let's first *create a new Excel file* based on the `tips` dataframe in the above example:

```
tips.to_excel("./tips.xlsx")
```

Should you wish to subsequently access the data in the `tips.xlsx` file, you can read it into your module using

```
tips_df = pd.read_excel("./tips.xlsx", index_col=0)
```

You have just read in an Excel file using pandas!

Limiting output

Spreadsheet programs will only show one screenful of data at a time and then allow you to scroll, so there isn't really a need to limit output. In pandas, you'll need to put a little more thought into controlling how your `DataFrames` are displayed.

By default, pandas will truncate output of large `DataFrames` to show the first and last rows. This can be overridden by *changing the pandas options*, or using `DataFrame.head()` or `DataFrame.tail()`.

```
In [8]: tips.head(5)
Out[8]:
   total_bill    tip      sex smoker  day   time  size
0       16.99  1.01  Female     No  Sun  Dinner    2
1       10.34  1.66    Male     No  Sun  Dinner    3
2       21.01  3.50    Male     No  Sun  Dinner    3
3       23.68  3.31    Male     No  Sun  Dinner    2
4       24.59  3.61  Female     No  Sun  Dinner    4
```

Exporting data

By default, desktop spreadsheet software will save to its respective file format (.xlsx, .ods, etc). You can, however, [save to other file formats](#).

pandas can create Excel files, CSV, or a number of other formats.

Data operations

Operations on columns

In spreadsheets, [formulas](#) are often created in individual cells and then [dragged](#) into other cells to compute them for other columns. In pandas, you're able to do operations on whole columns directly.

pandas provides vectorized operations by specifying the individual `Series` in the `DataFrame`. New columns can be assigned in the same way. The `DataFrame.drop()` method drops a column from the `DataFrame`.

```
In [9]: tips["total_bill"] = tips["total_bill"] - 2
```

```
In [10]: tips["new_bill"] = tips["total_bill"] / 2
```

```
In [11]: tips
```

```
Out[11]:
```

```
   total_bill    tip      sex smoker     day    time    size  new_bill
0       14.99  1.01  Female     No   Sun Dinner      2    7.495
1        8.34  1.66   Male     No   Sun Dinner      3    4.170
2       19.01  3.50   Male     No   Sun Dinner      3    9.505
3       21.68  3.31   Male     No   Sun Dinner      2   10.840
4       22.59  3.61 Female     No   Sun Dinner      4   11.295
..       ...
239      27.03  5.92   Male     No   Sat Dinner      3   13.515
240      25.18  2.00 Female    Yes   Sat Dinner      2   12.590
241      20.67  2.00   Male    Yes   Sat Dinner      2   10.335
242      15.82  1.75   Male     No   Sat Dinner      2    7.910
243      16.78  3.00 Female     No Thur Dinner      2    8.390
```

```
[244 rows x 8 columns]
```

```
In [12]: tips = tips.drop("new_bill", axis=1)
```

Note that we aren't having to tell it to do that subtraction cell-by-cell — pandas handles that for us. See [how to create new columns derived from existing columns](#).

Filtering

In Excel, filtering is done through a graphical menu.

The screenshot shows a Microsoft Excel spreadsheet with data in columns A through F. Column A contains row numbers (1 to 27) and column headers ('total_bill', 'tip', 'sex', 'smoker', 'day', 'time', 'size'). Column B contains numerical values for 'total_bill'. A filter dialog is open over the data, centered on row 1. The dialog title is 'Sort' and it shows 'total_bill' is sorted in Ascending order (A to Z). Below that is a 'Filter' section with a 'Greater Than' dropdown set to '10'. There are two radio buttons: 'And' (selected) and 'Or'. A 'Choose One' dropdown is empty. A 'Search' field is also present. At the bottom of the dialog is a list of numerical values: 3.07, 5.75, 7.25, 7.51, 7.56, and 7.74, each with an unchecked checkbox next to it. A 'Clear Filter' button is at the bottom right of the dialog.

DataFrames can be filtered in multiple ways; the most intuitive of which is using [boolean indexing](#).

```
In [13]: tips[tips["total_bill"] > 10]
```

```
Out[13]:
```

total_bill	tip	sex	smoker	day	time	size
------------	-----	-----	--------	-----	------	------

(continues on next page)

(continued from previous page)

0	14.99	1.01	Female	No	Sun	Dinner	2
2	19.01	3.50	Male	No	Sun	Dinner	3
3	21.68	3.31	Male	No	Sun	Dinner	2
4	22.59	3.61	Female	No	Sun	Dinner	4
5	23.29	4.71	Male	No	Sun	Dinner	4
..
239	27.03	5.92	Male	No	Sat	Dinner	3
240	25.18	2.00	Female	Yes	Sat	Dinner	2
241	20.67	2.00	Male	Yes	Sat	Dinner	2
242	15.82	1.75	Male	No	Sat	Dinner	2
243	16.78	3.00	Female	No	Thur	Dinner	2

[204 rows x 7 columns]

The above statement is simply passing a Series of True/False objects to the DataFrame, returning all rows with True.

```
In [14]: is_dinner = tips["time"] == "Dinner"
```

```
In [15]: is_dinner
```

```
Out[15]:
```

(continues on next page)

(continued from previous page)

242	15.82	1.75	Male	No	Sat	Dinner	2
243	16.78	3.00	Female	No	Thur	Dinner	2

[176 rows x 7 columns]

If/then logic

Let's say we want to make a bucket column with values of `low` and `high`, based on whether the `total_bill` is less or more than \$10.

In spreadsheets, logical comparison can be done with [conditional formulas](#). We'd use a formula of `=IF(A2 < 10, "low", "high")`, dragged to all cells in a new bucket column.

	A	B	C	D	E	F	G	H
1	total_bill	tip	sex	smoker	day	time	size	bucket
2	16.99	1.01	Female	No	Sun	Dinner	2	high
3	10.34	1.66	Male	No	Sun	Dinner	3	high
4	21.01	3.5	Male	No	Sun	Dinner	3	high
5	23.68	3.31	Male	No	Sun	Dinner	2	high
6	24.59	3.61	Female	No	Sun	Dinner	4	high
7	25.29	4.71	Male	No	Sun	Dinner	4	high
8	8.77	2	Male	No	Sun	Dinner	2	low
9	26.88	3.12	Male	No	Sun	Dinner	4	high
10	15.01	1.05	Male	No	Sun	Dinner	2	high

The same operation in pandas can be accomplished using the `where` method from `numpy`.

```
In [18]: tips["bucket"] = np.where(tips["total_bill"] < 10, "low", "high")
```

```
In [19]: tips
```

```
Out[19]:
```

	total_bill	tip	sex	smoker	day	time	size	bucket
0	14.99	1.01	Female	No	Sun	Dinner	2	high
1	8.34	1.66	Male	No	Sun	Dinner	3	low
2	19.01	3.5	Male	No	Sun	Dinner	3	high
3	21.68	3.31	Male	No	Sun	Dinner	2	high
4	22.59	3.61	Female	No	Sun	Dinner	4	high
..
239	27.03	5.92	Male	No	Sat	Dinner	3	high
240	25.18	2.0	Female	Yes	Sat	Dinner	2	high
241	20.67	2.0	Male	Yes	Sat	Dinner	2	high
242	15.82	1.75	Male	No	Sat	Dinner	2	high
243	16.78	3.0	Female	No	Thur	Dinner	2	high

[244 rows x 8 columns]

Date functionality

This section will refer to “dates”, but timestamps are handled similarly.

We can think of date functionality in two parts: parsing, and output. In spreadsheets, date values are generally parsed automatically, though there is a `DATEVALUE` function if you need it. In pandas, you need to explicitly convert plain text to datetime objects, either *while reading from a CSV* or *once in a DataFrame*.

Once parsed, spreadsheets display the dates in a default format, though the format can be changed. In pandas, you’ll generally want to keep dates as `datetime` objects while you’re doing calculations with them. Outputting *parts* of dates (such as the year) is done through `date functions` in spreadsheets, and `datetime properties` in pandas.

Given `date1` and `date2` in columns A and B of a spreadsheet, you might have these formulas:

column	formula
<code>date1_year</code>	<code>=YEAR(A2)</code>
<code>date2_month</code>	<code>=MONTH(B2)</code>
<code>date1_next</code>	<code>=DATE(YEAR(A2),MONTH(A2)+1,1)</code>
<code>months_between</code>	<code>=DATEDIF(A2,B2,"M")</code>

The equivalent pandas operations are shown below.

```
In [20]: tips["date1"] = pd.Timestamp("2013-01-15")
In [21]: tips["date2"] = pd.Timestamp("2015-02-15")
In [22]: tips["date1_year"] = tips["date1"].dt.year
In [23]: tips["date2_month"] = tips["date2"].dt.month
In [24]: tips["date1_next"] = tips["date1"] + pd.offsets.MonthBegin()
In [25]: tips["months_between"] = tips["date2"].dt.to_period("M") - tips[
...:     "date1"
...: ].dt.to_period("M")
...
In [26]: tips[
...:     ["date1", "date2", "date1_year", "date2_month", "date1_next", "months_
...: between"]
...: ]
...
Out[26]:
      date1      date2  date1_year  date2_month  date1_next  months_between
0  2013-01-15  2015-02-15      2013            2 2013-02-01 <25 * MonthEnds>

[244 rows x 6 columns]

See [Time series / date functionality](#) for more details.

Selection of columns

In spreadsheets, you can select columns you want by:

- Hiding columns
- Deleting columns
- Referencing a range from one worksheet into another

Since spreadsheet columns are typically [named](#) in a header row, renaming a column is simply a matter of changing the text in that first cell.

The same operations are expressed in pandas below.

Keep certain columns

```
In [27]: tips[["sex", "total_bill", "tip"]]
```

```
Out[27]:
```

	sex	total_bill	tip
0	Female	14.99	1.01
1	Male	8.34	1.66
2	Male	19.01	3.50
3	Male	21.68	3.31
4	Female	22.59	3.61
..
239	Male	27.03	5.92
240	Female	25.18	2.00
241	Male	20.67	2.00
242	Male	15.82	1.75
243	Female	16.78	3.00

[244 rows x 3 columns]

Drop a column

```
In [28]: tips.drop("sex", axis=1)
```

```
Out[28]:
```

	total_bill	tip	smoker	day	time	size
0	14.99	1.01	No	Sun	Dinner	2
1	8.34	1.66	No	Sun	Dinner	3
2	19.01	3.50	No	Sun	Dinner	3
3	21.68	3.31	No	Sun	Dinner	2
4	22.59	3.61	No	Sun	Dinner	4

(continues on next page)

(continued from previous page)

```
...      ...    ...    ...    ...    ...  
239    27.03  5.92   No   Sat  Dinner    3  
240    25.18  2.00  Yes  Sat  Dinner    2  
241    20.67  2.00  Yes  Sat  Dinner    2  
242    15.82  1.75   No  Sat  Dinner    2  
243    16.78  3.00   No Thur  Dinner    2  
  
[244 rows x 6 columns]
```

Rename a column

```
In [29]: tips.rename(columns={"total_bill": "total_bill_2"})  
Out[29]:
```

```
total_bill_2    tip     sex smoker    day    time    size  
0            14.99  1.01 Female    No Sun Dinner    2  
1             8.34  1.66  Male    No Sun Dinner    3  
2            19.01  3.50  Male    No Sun Dinner    3  
3            21.68  3.31  Male    No Sun Dinner    2  
4            22.59  3.61 Female    No Sun Dinner    4  
..      ...    ...    ...    ...    ...    ...  
239    27.03  5.92  Male    No Sat  Dinner    3  
240    25.18  2.00 Female  Yes  Sat  Dinner    2  
241    20.67  2.00  Male  Yes  Sat  Dinner    2  
242    15.82  1.75  Male    No Sat  Dinner    2  
243    16.78  3.00 Female    No Thur  Dinner    2
```

```
[244 rows x 7 columns]
```

Sorting by values

Sorting in spreadsheets is accomplished via [the sort dialog](#).

A screenshot of a Mac OS X Sort dialog box. The dialog is titled "Sort" and has a checkbox "My list has headers" checked. It shows a list of rows from a DataFrame, with the first few rows being 16.99, 1.01, Female, No, Sun, Dinner, 2; 10.34, 1.66, Male, No, Sun, Dinner, 3; and 21.01, 3.5, Male, No, Sun, Dinner, 2. Below the list is a table for defining sort levels. The first level is set to "Sort by" "sex" and "Order" "A to Z". The second level is set to "Then by" "total_bill" and "Order" "Smallest to Largest". At the bottom of the dialog are buttons for "+", "-", "Copy", "Options...", "Cancel", and "OK".

pandas has a `DataFrame.sort_values()` method, which takes a list of columns to sort by.

```
In [30]: tips = tips.sort_values(["sex", "total_bill"])
```

```
In [31]: tips
```

```
Out[31]:
```

	total_bill	tip	sex	smoker	day	time	size
67	1.07	1.00	Female	Yes	Sat	Dinner	1
92	3.75	1.00	Female	Yes	Fri	Dinner	2
111	5.25	1.00	Female	No	Sat	Dinner	1
145	6.35	1.50	Female	No	Thur	Lunch	2
135	6.51	1.25	Female	No	Thur	Lunch	2
..
182	43.35	3.50	Male	Yes	Sun	Dinner	3
156	46.17	5.00	Male	No	Sun	Dinner	6
59	46.27	6.73	Male	No	Sat	Dinner	4
212	46.33	9.00	Male	No	Sat	Dinner	4
170	48.81	10.00	Male	Yes	Sat	Dinner	3

[244 rows x 7 columns]

String processing

Finding length of string

In spreadsheets, the number of characters in text can be found with the `LEN` function. This can be used with the `TRIM` function to remove extra whitespace.

```
=LEN(TRIM(A2))
```

You can find the length of a character string with `Series.str.len()`. In Python 3, all strings are Unicode strings. `len` includes trailing blanks. Use `len` and `rstrip` to exclude trailing blanks.

```
In [32]: tips["time"].str.len()
```

```
Out[32]:
```

```
67      6  
92      6  
111     6  
145     5  
135     5  
..  
182     6  
156     6  
59      6  
212     6  
170     6  
Name: time, Length: 244, dtype: int64
```

```
In [33]: tips["time"].str.rstrip().str.len()
```

```
Out[33]:
```

```
67      6  
92      6  
111     6  
145     5  
135     5  
..  
182     6  
156     6  
59      6  
212     6  
170     6  
Name: time, Length: 244, dtype: int64
```

Note this will still include multiple spaces within the string, so isn't 100% equivalent.

Finding position of substring

The `FIND` spreadsheet function returns the position of a substring, with the first character being 1.

total_bill	tip	sex	smoker	day	time	size
16.99	1.01	Female	No	Sun	Dinner	2
10.34	1.66	Male	No	Sun	Dinner	3
21.01	3.5	Male	No	Sun	Dinner	2
23.68						
24.59						
25.29						
8.77						
26.88						
15.04						
14.78						
10.27						
35.26						
15.42						
18.43						
14.83						
21.58						
10.33						
16.29						
16.97						
20.65						

You can find the position of a character in a column of strings with the `Series.str.find()` method. `find` searches for the first position of the substring. If the substring is found, the method returns its position. If not found, it returns -1. Keep in mind that Python indexes are zero-based.

```
In [34]: tips["sex"].str.find("ale")
```

```
Out[34]:
```

```
67      3
92      3
111     3
145     3
135     3
...
182      1
156      1
59       1
212     1
170      1
Name: sex, Length: 244, dtype: int64
```

Extracting substring by position

Spreadsheets have a `MID` formula for extracting a substring from a given position. To get the first character:

```
=MID(A2,1,1)
```

With pandas you can use `[]` notation to extract a substring from a string by position locations. Keep in mind that Python indexes are zero-based.

```
In [35]: tips["sex"].str[0:1]
```

```
Out[35]:
```

```
67      F
92      F
```

(continues on next page)

(continued from previous page)

```
111    F
145    F
135    F
     ..
182    M
156    M
59     M
212    M
170    M
Name: sex, Length: 244, dtype: object
```

Extracting nth word

In Excel, you might use the `Text to Columns Wizard` for splitting text and retrieving a specific column. (Note it's possible to do so through a formula as well.)

The simplest way to extract words in pandas is to split the strings by spaces, then reference the word by index. Note there are more powerful approaches should you need them.

```
In [36]: firstlast = pd.DataFrame({"String": ["John Smith", "Jane Cook"]})

In [37]: firstlast["First_Name"] = firstlast["String"].str.split(" ", expand=True)[0]

In [38]: firstlast["Last_Name"] = firstlast["String"].str.rsplit(" ", expand=True)[1]

In [39]: firstlast
Out[39]:
   String First_Name Last_Name
0  John Smith      John      Smith
1  Jane Cook       Jane      Cook
```

Changing case

Spreadsheets provide `UPPER`, `LOWER`, and `PROPER` functions for converting text to upper, lower, and title case, respectively.

The equivalent pandas methods are `Series.str.upper()`, `Series.str.lower()`, and `Series.str.title()`.

```
In [40]: firstlast = pd.DataFrame({"string": ["John Smith", "Jane Cook"]})

In [41]: firstlast["upper"] = firstlast["string"].str.upper()

In [42]: firstlast["lower"] = firstlast["string"].str.lower()

In [43]: firstlast["title"] = firstlast["string"].str.title()

In [44]: firstlast
Out[44]:
   string      upper      lower      title
0  John Smith  JOHN SMITH  john smith  John Smith
1  Jane Cook   JANE COOK   jane cook   Jane Cook
```

Merging

The following tables will be used in the merge examples:

```
In [45]: df1 = pd.DataFrame({"key": ["A", "B", "C", "D"], "value": np.random.randn(4)})
```

```
In [46]: df1
```

```
Out[46]:
```

	key	value
0	A	0.469112
1	B	-0.282863
2	C	-1.509059
3	D	-1.135632

```
In [47]: df2 = pd.DataFrame({"key": ["B", "D", "D", "E"], "value": np.random.randn(4)})
```

```
In [48]: df2
```

```
Out[48]:
```

	key	value
0	B	1.212112
1	D	-0.173215
2	D	0.119209
3	E	-1.044236

In Excel, there are merging of tables can be done through a VLOOKUP.

		<input type="button" value="▼"/>	<input type="button" value="X"/>	<input type="button" value="✓"/>	<input type="button" value="fx"/>	=VLOOKUP([@key],Table2[#All],2,FALSE)		
A	B	C		D	E	F		
Table1								
Table2								
key	<input type="button" value="▼"/>	value_x	<input type="button" value="▼"/>	value_y	<input type="button" value="▼"/>			
A		0.469112		#N/A				
B		-0.282863		1.212112				
C		-1.509059		#N/A				
D		-1.135632		-0.173215				

pandas DataFrames have a `merge()` method, which provides similar functionality. The data does not have to be sorted ahead of time, and different join types are accomplished via the `how` keyword.

```
In [49]: inner_join = df1.merge(df2, on=["key"], how="inner")
```

```
In [50]: inner_join
```

```
Out[50]:
```

	key	value_x	value_y
0	B	-0.282863	1.212112
1	D	-1.135632	-0.173215
2	D	-1.135632	0.119209

(continues on next page)

(continued from previous page)

```
In [51]: left_join = df1.merge(df2, on=["key"], how="left")
```

```
In [52]: left_join
```

```
Out[52]:
```

```
key    value_x    value_y
0     A   0.469112      NaN
1     B  -0.282863  1.212112
2     C  -1.509059      NaN
3     D  -1.135632 -0.173215
4     D  -1.135632  0.119209
```

```
In [53]: right_join = df1.merge(df2, on=["key"], how="right")
```

```
In [54]: right_join
```

```
Out[54]:
```

```
key    value_x    value_y
0     B  -0.282863  1.212112
1     D  -1.135632 -0.173215
2     D  -1.135632  0.119209
3     E      NaN -1.044236
```

```
In [55]: outer_join = df1.merge(df2, on=["key"], how="outer")
```

```
In [56]: outer_join
```

```
Out[56]:
```

```
key    value_x    value_y
0     A   0.469112      NaN
1     B  -0.282863  1.212112
2     C  -1.509059      NaN
3     D  -1.135632 -0.173215
4     D  -1.135632  0.119209
5     E      NaN -1.044236
```

merge has a number of advantages over VLOOKUP:

- The lookup value doesn't need to be the first column of the lookup table
- If multiple rows are matched, there will be one row for each match, instead of just the first
- It will include all columns from the lookup table, instead of just a single specified column
- It supports *more complex join operations*

Other considerations

Fill Handle

Create a series of numbers following a set pattern in a certain set of cells. In a spreadsheet, this would be done by shift+drag after entering the first number or by entering the first two or three values and then dragging.

This can be achieved by creating a series and assigning it to the desired cells.

```
In [57]: df = pd.DataFrame({"AAA": [1] * 8, "BBB": list(range(0, 8))})
```

```
In [58]: df
```

```
Out[58]:
```

	AAA	BBB
0	1	0
1	1	1
2	1	2
3	1	3
4	1	4
5	1	5
6	1	6
7	1	7

```
In [59]: series = list(range(1, 5))
```

```
In [60]: series
```

```
Out[60]: [1, 2, 3, 4]
```

```
In [61]: df.loc[2:5, "AAA"] = series
```

```
In [62]: df
```

```
Out[62]:
```

	AAA	BBB
0	1	0
1	1	1
2	1	2
3	2	3
4	3	4
5	4	5
6	1	6
7	1	7

Drop Duplicates

Excel has built-in functionality for removing duplicate values. This is supported in pandas via `drop_duplicates()`.

```
In [63]: df = pd.DataFrame(
    ....:     {
    ....:         "class": ["A", "A", "A", "B", "C", "D"],
    ....:         "student_count": [42, 35, 42, 50, 47, 45],
    ....:         "all_pass": ["Yes", "Yes", "Yes", "No", "No", "Yes"],
    ....:     }
    ....: )
```

```
In [64]: df.drop_duplicates()
```

```
Out[64]:
```

	class	student_count	all_pass
0	A	42	Yes
1	A	35	Yes

(continues on next page)

(continued from previous page)

3	B	50	No
4	C	47	No
5	D	45	Yes

In [65]: df.drop_duplicates(["class", "student_count"])**Out[65]:**

	class	student_count	all_pass
0	A	42	Yes
1	A	35	Yes
3	B	50	No
4	C	47	No
5	D	45	Yes

Pivot Tables

PivotTables from spreadsheets can be replicated in pandas through *Reshaping and pivot tables*. Using the tips dataset again, let's find the average gratuity by size of the party and sex of the server.

In Excel, we use the following configuration for the PivotTable:

	A	B	C	D	E	F
1						
2						
3	Average tip	sex				
4	size	Female	Male	(blank)	Grand Total	
5		1	1.276666667	1.92		1.4375
6		2	2.528448276	2.614183673		2.582307692
7		3	3.25	3.476666667		3.393157895
8		4	4.021111111	4.172142857		4.135405405
9		5	5.14	3.75		4.028
10		6	4.6	5.85		5.225
11	(blank)					
12	Grand Total	2.833448276	3.089617834		2.998278689	
13						
14						
15						
16						

PivotTable Fields

Choose fields:

- total_bill
- tip
- sex
- smoker
- day
- time
- size

Drag fields between areas below:

FILTERS

COLUMNS

ROWS

VALUES

The equivalent in pandas:

In [66]: pd.pivot_table(
.....: tips, values="tip", index=["size"], columns=["sex"], aggfunc=np.average
.....:
.....:
Out[66]:

sex	Female	Male
size		
1	1.276667	1.920000
2	2.528448	2.614184
3	3.250000	3.476667
4	4.021111	4.172143

(continues on next page)

(continued from previous page)

5	5.140000	3.750000
6	4.600000	5.850000

Adding a row

Assuming we are using a `RangeIndex` (numbered 0, 1, etc.), we can use `concat()` to add a row to the bottom of a DataFrame.

In [67]: df

Out[67]:

```
class student_count all_pass
0    A          42     Yes
1    A          35     Yes
2    A          42     Yes
3    B          50      No
4    C          47      No
5    D          45     Yes
```

In [68]: new_row = pd.DataFrame([["E", 51, True]],
.....: columns=["class", "student_count", "all_pass"])
.....:

In [69]: pd.concat([df, new_row])

Out[69]:

```
class student_count all_pass
0    A          42     Yes
1    A          35     Yes
2    A          42     Yes
3    B          50      No
4    C          47      No
5    D          45     Yes
0    E          51     True
```

Find and Replace

Excel's Find dialog takes you to cells that match, one by one. In pandas, this operation is generally done for an entire column or DataFrame at once through `conditional expressions`.

In [70]: tips

Out[70]:

	total_bill	tip	sex	smoker	day	time	size
67	1.07	1.00	Female	Yes	Sat	Dinner	1
92	3.75	1.00	Female	Yes	Fri	Dinner	2
111	5.25	1.00	Female	No	Sat	Dinner	1
145	6.35	1.50	Female	No	Thur	Lunch	2
135	6.51	1.25	Female	No	Thur	Lunch	2
..
182	43.35	3.50	Male	Yes	Sun	Dinner	3
156	46.17	5.00	Male	No	Sun	Dinner	6

(continues on next page)

(continued from previous page)

```
59      46.27   6.73    Male     No   Sat Dinner     4
212     46.33   9.00    Male     No   Sat Dinner     4
170     48.81  10.00    Male    Yes   Sat Dinner     3
```

[244 rows x 7 columns]

In [71]: tips == "Sun"

Out[71]:

```
total_bill      tip     sex smoker     day    time    size
67      False  False  False  False  False  False  False
92      False  False  False  False  False  False  False
111     False  False  False  False  False  False  False
145     False  False  False  False  False  False  False
135     False  False  False  False  False  False  False
...
182      False  False  False  False  True   False  False
156     False  False  False  False  True   False  False
59      False  False  False  False  False  False  False
212     False  False  False  False  False  False  False
170     False  False  False  False  False  False  False
```

[244 rows x 7 columns]

In [72]: tips["day"].str.contains("S")

Out[72]:

```
67      True
92     False
111     True
145    False
135    False
...
182     True
156     True
59      True
212     True
170     True
Name: day, Length: 244, dtype: bool
```

pandas' `replace()` is comparable to Excel's Replace All.

In [73]: tips.replace("Thu", "Thursday")

Out[73]:

```
total_bill      tip     sex smoker     day    time    size
67      1.07   1.00  Female    Yes   Sat Dinner     1
92      3.75   1.00  Female    Yes   Fri Dinner     2
111     5.25   1.00  Female    No    Sat Dinner     1
145     6.35   1.50  Female    No   Thur Lunch     2
135     6.51   1.25  Female    No   Thur Lunch     2
...
182     43.35  3.50    Male    Yes   Sun Dinner     3
156     46.17  5.00    Male    No   Sun Dinner     6
59      46.27   6.73    Male     No   Sat Dinner     4
```

(continues on next page)

(continued from previous page)

212	46.33	9.00	Male	No	Sat	Dinner	4
170	48.81	10.00	Male	Yes	Sat	Dinner	3

[244 rows x 7 columns]

Comparison with SAS

For potential users coming from [SAS](#) this page is meant to demonstrate how different SAS operations would be performed in pandas.

If you're new to pandas, you might want to first read through [10 Minutes to pandas](#) to familiarize yourself with the library.

As is customary, we import pandas and NumPy as follows:

In [1]: `import pandas as pd`

In [2]: `import numpy as np`

Data structures

General terminology translation

pandas	SAS
<code>DataFrame</code>	data set
<code>column</code>	variable
<code>row</code>	observation
<code>groupby</code>	BY-group
<code>NaN</code>	.

DataFrame

A `DataFrame` in pandas is analogous to a SAS data set - a two-dimensional data source with labeled columns that can be of different types. As will be shown in this document, almost any operation that can be applied to a data set using SAS's DATA step, can also be accomplished in pandas.

Series

A `Series` is the data structure that represents one column of a `DataFrame`. SAS doesn't have a separate data structure for a single column, but in general, working with a `Series` is analogous to referencing a column in the DATA step.

Index

Every DataFrame and Series has an Index - which are labels on the *rows* of the data. SAS does not have an exactly analogous concept. A data set's rows are essentially unlabeled, other than an implicit integer index that can be accessed during the DATA step (_N_).

In pandas, if no index is specified, an integer index is also used by default (first row = 0, second row = 1, and so on). While using a labeled Index or MultiIndex can enable sophisticated analyses and is ultimately an important part of pandas to understand, for this comparison we will essentially ignore the Index and just treat the DataFrame as a collection of columns. Please see the [indexing documentation](#) for much more on how to use an Index effectively.

Copies vs. in place operations

Most pandas operations return copies of the Series/DataFrame. To make the changes “stick”, you’ll need to either assign to a new variable:

```
sorted_df = df.sort_values("col1")
```

or overwrite the original one:

```
df = df.sort_values("col1")
```

Note: You will see an `inplace=True` keyword argument available for some methods:

```
df.sort_values("col1", inplace=True)
```

Its use is discouraged. [More information.](#)

Data input / output

Constructing a DataFrame from values

A SAS data set can be built from specified values by placing the data after a `datalines` statement and specifying the column names.

```
data df;
  input x y;
  datalines;
  1 2
  3 4
  5 6
  ;
run;
```

A pandas DataFrame can be constructed in many different ways, but for a small number of values, it is often convenient to specify it as a Python dictionary, where the keys are the column names and the values are the data.

```
In [1]: df = pd.DataFrame({"x": [1, 3, 5], "y": [2, 4, 6]})
```

```
In [2]: df
```

(continues on next page)

(continued from previous page)

Out[2]:

	x	y
0	1	2
1	3	4
2	5	6

Reading external data

Like SAS, pandas provides utilities for reading in data from many formats. The `tips` dataset, found within the pandas tests (`csv`) will be used in many of the following examples.

SAS provides PROC IMPORT to read csv data into a data set.

```
proc import datafile='tips.csv' dbms=csv out=tips replace;
    getnames=yes;
run;
```

The pandas method is `read_csv()`, which works similarly.

```
In [3]: url = (
...:     "https://raw.github.com/pandas-dev/"
...:     "pandas/main/pandas/tests/io/data/csv/tips.csv"
...: )
...:
```

```
In [4]: tips = pd.read_csv(url)
```

```
In [5]: tips
```

Out[5]:

	total_bill	tip	sex	smoker	day	time	size
0	16.99	1.01	Female	No	Sun	Dinner	2
1	10.34	1.66	Male	No	Sun	Dinner	3
2	21.01	3.50	Male	No	Sun	Dinner	3
3	23.68	3.31	Male	No	Sun	Dinner	2
4	24.59	3.61	Female	No	Sun	Dinner	4
..
239	29.03	5.92	Male	No	Sat	Dinner	3
240	27.18	2.00	Female	Yes	Sat	Dinner	2
241	22.67	2.00	Male	Yes	Sat	Dinner	2
242	17.82	1.75	Male	No	Sat	Dinner	2
243	18.78	3.00	Female	No	Thur	Dinner	2

[244 rows x 7 columns]

Like PROC IMPORT, `read_csv` can take a number of parameters to specify how the data should be parsed. For example, if the data was instead tab delimited, and did not have column names, the pandas command would be:

```
tips = pd.read_csv("tips.csv", sep="\t", header=None)

# alternatively, read_table is an alias to read_csv with tab delimiter
tips = pd.read_table("tips.csv", header=None)
```

In addition to text/csv, pandas supports a variety of other data formats such as Excel, HDF5, and SQL databases. These are all read via a `pd.read_*` function. See the [IO documentation](#) for more details.

Limiting output

By default, pandas will truncate output of large `DataFrames` to show the first and last rows. This can be overridden by *changing the pandas options*, or using `DataFrame.head()` or `DataFrame.tail()`.

```
In [1]: tips.head(5)
Out[1]:
   total_bill  tip    sex smoker  day   time  size
0      16.99  1.01  Female     No  Sun  Dinner    2
1      10.34  1.66    Male     No  Sun  Dinner    3
2      21.01  3.50    Male     No  Sun  Dinner    3
3      23.68  3.31    Male     No  Sun  Dinner    2
4      24.59  3.61  Female     No  Sun  Dinner    4
```

The equivalent in SAS would be:

```
proc print data=df(obs=5);
run;
```

Exporting data

The inverse of PROC IMPORT in SAS is PROC EXPORT

```
proc export data=tips outfile='tips2.csv' dbms=csv;
run;
```

Similarly in pandas, the opposite of `read_csv` is `to_csv()`, and other data formats follow a similar api.

```
tips.to_csv("tips2.csv")
```

Data operations

Operations on columns

In the DATA step, arbitrary math expressions can be used on new or existing columns.

```
data tips;
  set tips;
  total_bill = total_bill - 2;
  new_bill = total_bill / 2;
run;
```

pandas provides vectorized operations by specifying the individual `Series` in the `DataFrame`. New columns can be assigned in the same way. The `DataFrame.drop()` method drops a column from the `DataFrame`.

```
In [1]: tips["total_bill"] = tips["total_bill"] - 2
```

```
In [2]: tips["new_bill"] = tips["total_bill"] / 2
```

```
In [3]: tips
```

```
Out[3]:
```

	total_bill	tip	sex	smoker	day	time	size	new_bill
0	14.99	1.01	Female	No	Sun	Dinner	2	7.495
1	8.34	1.66	Male	No	Sun	Dinner	3	4.170
2	19.01	3.50	Male	No	Sun	Dinner	3	9.505
3	21.68	3.31	Male	No	Sun	Dinner	2	10.840
4	22.59	3.61	Female	No	Sun	Dinner	4	11.295
..
239	27.03	5.92	Male	No	Sat	Dinner	3	13.515
240	25.18	2.00	Female	Yes	Sat	Dinner	2	12.590
241	20.67	2.00	Male	Yes	Sat	Dinner	2	10.335
242	15.82	1.75	Male	No	Sat	Dinner	2	7.910
243	16.78	3.00	Female	No	Thur	Dinner	2	8.390

[244 rows x 8 columns]

```
In [4]: tips = tips.drop("new_bill", axis=1)
```

Filtering

Filtering in SAS is done with an `if` or `where` statement, on one or more columns.

```
data tips;
  set tips;
  if total_bill > 10;
run;

data tips;
  set tips;
  where total_bill > 10;
  /* equivalent in this case - where happens before the
     DATA step begins and can also be used in PROC statements */
run;
```

DataFrames can be filtered in multiple ways; the most intuitive of which is using `boolean indexing`.

```
In [1]: tips[tips["total_bill"] > 10]
```

```
Out[1]:
```

	total_bill	tip	sex	smoker	day	time	size
0	14.99	1.01	Female	No	Sun	Dinner	2
2	19.01	3.50	Male	No	Sun	Dinner	3
3	21.68	3.31	Male	No	Sun	Dinner	2
4	22.59	3.61	Female	No	Sun	Dinner	4
5	23.29	4.71	Male	No	Sun	Dinner	4
..
239	27.03	5.92	Male	No	Sat	Dinner	3
240	25.18	2.00	Female	Yes	Sat	Dinner	2

(continues on next page)

(continued from previous page)

```
241    20.67  2.00   Male    Yes   Sat  Dinner    2
242    15.82  1.75   Male     No   Sat  Dinner    2
243    16.78  3.00 Female    No Thur  Dinner    2
```

[204 rows x 7 columns]

The above statement is simply passing a Series of True/False objects to the DataFrame, returning all rows with True.

```
In [1]: is_dinner = tips["time"] == "Dinner"
```

```
In [2]: is_dinner
```

```
Out[2]:
```

```
0      True
1      True
2      True
3      True
4      True
...
239    True
240    True
241    True
242    True
243    True
Name: time, Length: 244, dtype: bool
```

```
In [3]: is_dinner.value_counts()
```

```
Out[3]:
```

```
True    176
False   68
Name: time, dtype: int64
```

```
In [4]: tips[is_dinner]
```

```
Out[4]:
```

	total_bill	tip	sex	smoker	day	time	size
0	14.99	1.01	Female	No	Sun	Dinner	2
1	8.34	1.66	Male	No	Sun	Dinner	3
2	19.01	3.50	Male	No	Sun	Dinner	3
3	21.68	3.31	Male	No	Sun	Dinner	2
4	22.59	3.61	Female	No	Sun	Dinner	4
..
239	27.03	5.92	Male	No	Sat	Dinner	3
240	25.18	2.00	Female	Yes	Sat	Dinner	2
241	20.67	2.00	Male	Yes	Sat	Dinner	2
242	15.82	1.75	Male	No	Sat	Dinner	2
243	16.78	3.00	Female	No	Thur	Dinner	2

[176 rows x 7 columns]

If/then logic

In SAS, if/then logic can be used to create new columns.

```
data tips;
  set tips;
  format bucket $4.;

  if total_bill < 10 then bucket = 'low';
  else bucket = 'high';
run;
```

The same operation in pandas can be accomplished using the `where` method from `numpy`.

```
In [1]: tips["bucket"] = np.where(tips["total_bill"] < 10, "low", "high")
```

```
In [2]: tips
```

```
Out[2]:
```

	total_bill	tip	sex	smoker	day	time	size	bucket
0	14.99	1.01	Female	No	Sun	Dinner	2	high
1	8.34	1.66	Male	No	Sun	Dinner	3	low
2	19.01	3.50	Male	No	Sun	Dinner	3	high
3	21.68	3.31	Male	No	Sun	Dinner	2	high
4	22.59	3.61	Female	No	Sun	Dinner	4	high
..
239	27.03	5.92	Male	No	Sat	Dinner	3	high
240	25.18	2.00	Female	Yes	Sat	Dinner	2	high
241	20.67	2.00	Male	Yes	Sat	Dinner	2	high
242	15.82	1.75	Male	No	Sat	Dinner	2	high
243	16.78	3.00	Female	No	Thur	Dinner	2	high

[244 rows x 8 columns]

Date functionality

SAS provides a variety of functions to do operations on date/datetime columns.

```
data tips;
  set tips;
  format date1 date2 date1_plusmonth mmddyy10.;
  date1 = mdy(1, 15, 2013);
  date2 = mdy(2, 15, 2015);
  date1_year = year(date1);
  date2_month = month(date2);
  * shift date to beginning of next interval;
  date1_next = intnx('MONTH', date1, 1);
  * count intervals between dates;
  months_between = intck('MONTH', date1, date2);
run;
```

The equivalent pandas operations are shown below. In addition to these functions pandas supports other Time Series features not available in Base SAS (such as resampling and custom offsets) - see the [timeseries documentation](#) for more details.

```
In [1]: tips["date1"] = pd.Timestamp("2013-01-15")

In [2]: tips["date2"] = pd.Timestamp("2015-02-15")

In [3]: tips["date1_year"] = tips["date1"].dt.year

In [4]: tips["date2_month"] = tips["date2"].dt.month

In [5]: tips["date1_next"] = tips["date1"] + pd.offsets.MonthBegin()

In [6]: tips["months_between"] = tips["date2"].dt.to_period("M") - tips[
...:     "date1"
...: ].dt.to_period("M")
...:

In [7]: tips[
...:     ["date1", "date2", "date1_year", "date2_month", "date1_next", "months_between"]
...: ]
...:

Out[7]:
      date1      date2  date1_year  date2_month date1_next  months_between
0  2013-01-15  2015-02-15        2013            2 2013-02-01 <25 * MonthEnds>
1  2013-01-15  2015-02-15        2013            2 2013-02-01 <25 * MonthEnds>
2  2013-01-15  2015-02-15        2013            2 2013-02-01 <25 * MonthEnds>
3  2013-01-15  2015-02-15        2013            2 2013-02-01 <25 * MonthEnds>
4  2013-01-15  2015-02-15        2013            2 2013-02-01 <25 * MonthEnds>
...
239  ...
240  ...
241  ...
242  ...
243  ...

[244 rows x 6 columns]
```

Selection of columns

SAS provides keywords in the DATA step to select, drop, and rename columns.

```
data tips;
  set tips;
  keep sex total_bill tip;
run;

data tips;
  set tips;
  drop sex;
run;

data tips;
```

(continues on next page)

(continued from previous page)

```
set tips;
rename total_bill=total_bill_2;
run;
```

The same operations are expressed in pandas below.

Keep certain columns

```
In [1]: tips[["sex", "total_bill", "tip"]]
Out[1]:
   sex  total_bill  tip
0  Female      14.99  1.01
1    Male       8.34  1.66
2    Male      19.01  3.50
3    Male      21.68  3.31
4  Female      22.59  3.61
..     ...
239   Male      27.03  5.92
240 Female      25.18  2.00
241   Male      20.67  2.00
242   Male      15.82  1.75
243 Female      16.78  3.00

[244 rows x 3 columns]
```

Drop a column

```
In [2]: tips.drop("sex", axis=1)
Out[2]:
   total_bill  tip  smoker  day  time  size
0      14.99  1.01    No  Sun Dinner    2
1       8.34  1.66    No  Sun Dinner    3
2      19.01  3.50    No  Sun Dinner    3
3      21.68  3.31    No  Sun Dinner    2
4      22.59  3.61    No  Sun Dinner    4
..     ...
239    27.03  5.92    No  Sat Dinner    3
240    25.18  2.00   Yes  Sat Dinner    2
241    20.67  2.00   Yes  Sat Dinner    2
242    15.82  1.75    No  Sat Dinner    2
243    16.78  3.00    No Thur Dinner    2

[244 rows x 6 columns]
```

Rename a column

```
In [1]: tips.rename(columns={"total_bill": "total_bill_2"})
Out[1]:
   total_bill_2  tip    sex smoker  day    time  size
0        14.99  1.01  Female     No  Sun Dinner    2
1         8.34  1.66   Male     No  Sun Dinner    3
2        19.01  3.50   Male     No  Sun Dinner    3
3        21.68  3.31   Male     No  Sun Dinner    2
4        22.59  3.61 Female     No  Sun Dinner    4
...
239      27.03  5.92   Male     No  Sat Dinner    3
240      25.18  2.00 Female    Yes  Sat Dinner    2
241      20.67  2.00   Male    Yes  Sat Dinner    2
242      15.82  1.75   Male     No  Sat Dinner    2
243      16.78  3.00 Female     No Thur Dinner    2

[244 rows x 7 columns]
```

Sorting by values

Sorting in SAS is accomplished via PROC SORT

```
proc sort data=tips;
  by sex total_bill;
run;
```

pandas has a `DataFrame.sort_values()` method, which takes a list of columns to sort by.

```
In [1]: tips = tips.sort_values(["sex", "total_bill"])

In [2]: tips
Out[2]:
   total_bill  tip    sex smoker  day    time  size
67       1.07  1.00 Female    Yes  Sat Dinner    1
92       3.75  1.00 Female    Yes  Fri Dinner    2
111      5.25  1.00 Female     No  Sat Dinner    1
145      6.35  1.50 Female     No Thur Lunch     2
135      6.51  1.25 Female     No Thur Lunch     2
...
182      43.35  3.50   Male    Yes  Sun Dinner    3
156      46.17  5.00   Male     No  Sun Dinner    6
59       46.27  6.73   Male     No  Sat Dinner    4
212      46.33  9.00   Male     No  Sat Dinner    4
170      48.81 10.00   Male    Yes  Sat Dinner    3

[244 rows x 7 columns]
```

String processing

Finding length of string

SAS determines the length of a character string with the LENGTHN and LENGTHC functions. LENGTHN excludes trailing blanks and LENGTHC includes trailing blanks.

```
data _null_;
set tips;
put(LENGTHN(time));
put(LENGTHC(time));
run;
```

You can find the length of a character string with `Series.str.len()`. In Python 3, all strings are Unicode strings. `len` includes trailing blanks. Use `len` and `rstrip` to exclude trailing blanks.

```
In [1]: tips["time"].str.len()
Out[1]:
67      6
92      6
111     6
145     5
135     5
...
182      6
156     6
59      6
212     6
170     6
Name: time, Length: 244, dtype: int64

In [2]: tips["time"].str.rstrip().str.len()
Out[2]:
67      6
92      6
111     6
145     5
135     5
...
182      6
156     6
59      6
212     6
170     6
Name: time, Length: 244, dtype: int64
```

Finding position of substring

SAS determines the position of a character in a string with the `FINDW` function. `FINDW` takes the string defined by the first argument and searches for the first position of the substring you supply as the second argument.

```
data _null_;
set tips;
put(FINDW(sex, 'ale'));
run;
```

You can find the position of a character in a column of strings with the `Series.str.find()` method. `find` searches for the first position of the substring. If the substring is found, the method returns its position. If not found, it returns `-1`. Keep in mind that Python indexes are zero-based.

```
In [1]: tips["sex"].str.find("ale")
Out[1]:
67      3
92      3
111     3
145     3
135     3
...
182      1
156      1
59       1
212     1
170      1
Name: sex, Length: 244, dtype: int64
```

Extracting substring by position

SAS extracts a substring from a string based on its position with the `SUBSTR` function.

```
data _null_;
set tips;
put(substr(sex,1,1));
run;
```

With pandas you can use `[]` notation to extract a substring from a string by position locations. Keep in mind that Python indexes are zero-based.

```
In [1]: tips["sex"].str[0:1]
Out[1]:
67      F
92      F
111     F
145     F
135     F
...
182      M
156      M
59       M
```

(continues on next page)

(continued from previous page)

```
212      M
170      M
Name: sex, Length: 244, dtype: object
```

Extracting nth word

The SAS `SCAN` function returns the nth word from a string. The first argument is the string you want to parse and the second argument specifies which word you want to extract.

```
data firstlast;
input String $60.;
First_Name = scan(string, 1);
Last_Name = scan(string, -1);
datalines2;
John Smith;
Jane Cook;
;;
run;
```

The simplest way to extract words in pandas is to split the strings by spaces, then reference the word by index. Note there are more powerful approaches should you need them.

```
In [1]: firstlast = pd.DataFrame({"String": ["John Smith", "Jane Cook"]})

In [2]: firstlast["First_Name"] = firstlast["String"].str.split(" ", expand=True)[0]

In [3]: firstlast["Last_Name"] = firstlast["String"].str.rsplit(" ", expand=True)[1]

In [4]: firstlast
Out[4]:
      String First_Name Last_Name
0   John Smith       John     Smith
1   Jane Cook        Jane     Cook
```

Changing case

The SAS `UPCASE LOWCASE` and `PROPCASE` functions change the case of the argument.

```
data firstlast;
input String $60.;
string_up = UPCASE(string);
string_low = LOWCASE(string);
string_prop = PROPCASE(string);
datalines2;
John Smith;
Jane Cook;
;;
run;
```

The equivalent pandas methods are `Series.str.upper()`, `Series.str.lower()`, and `Series.str.title()`.

```
In [1]: firstlast = pd.DataFrame({"string": ["John Smith", "Jane Cook"]})

In [2]: firstlast["upper"] = firstlast["string"].str.upper()

In [3]: firstlast["lower"] = firstlast["string"].str.lower()

In [4]: firstlast["title"] = firstlast["string"].str.title()

In [5]: firstlast
Out[5]:
      string      upper      lower      title
0  John Smith  JOHN SMITH  john smith  John Smith
1   Jane Cook   JANE COOK   jane cook   Jane Cook
```

Merging

The following tables will be used in the merge examples:

```
In [1]: df1 = pd.DataFrame({"key": ["A", "B", "C", "D"], "value": np.random.randn(4)})

In [2]: df1
Out[2]:
    key      value
0   A  0.469112
1   B -0.282863
2   C -1.509059
3   D -1.135632

In [3]: df2 = pd.DataFrame({"key": ["B", "D", "D", "E"], "value": np.random.randn(4)})

In [4]: df2
Out[4]:
    key      value
0   B  1.212112
1   D -0.173215
2   D  0.119209
3   E -1.044236
```

In SAS, data must be explicitly sorted before merging. Different types of joins are accomplished using the `in=` dummy variables to track whether a match was found in one or both input frames.

```
proc sort data=df1;
  by key;
run;

proc sort data=df2;
  by key;
run;

data left_join inner_join right_join outer_join;
  merge df1(in=a) df2(in=b);
```

(continues on next page)

(continued from previous page)

```

if a and b then output inner_join;
if a then output left_join;
if b then output right_join;
if a or b then output outer_join;
run;

```

pandas DataFrames have a `merge()` method, which provides similar functionality. The data does not have to be sorted ahead of time, and different join types are accomplished via the `how` keyword.

```
In [1]: inner_join = df1.merge(df2, on=["key"], how="inner")
```

```
In [2]: inner_join
```

```
Out[2]:
```

	key	value_x	value_y
0	B	-0.282863	1.212112
1	D	-1.135632	-0.173215
2	D	-1.135632	0.119209

```
In [3]: left_join = df1.merge(df2, on=["key"], how="left")
```

```
In [4]: left_join
```

```
Out[4]:
```

	key	value_x	value_y
0	A	0.469112	NaN
1	B	-0.282863	1.212112
2	C	-1.509059	NaN
3	D	-1.135632	-0.173215
4	D	-1.135632	0.119209

```
In [5]: right_join = df1.merge(df2, on=["key"], how="right")
```

```
In [6]: right_join
```

```
Out[6]:
```

	key	value_x	value_y
0	B	-0.282863	1.212112
1	D	-1.135632	-0.173215
2	D	-1.135632	0.119209
3	E	NaN	-1.044236

```
In [7]: outer_join = df1.merge(df2, on=["key"], how="outer")
```

```
In [8]: outer_join
```

```
Out[8]:
```

	key	value_x	value_y
0	A	0.469112	NaN
1	B	-0.282863	1.212112
2	C	-1.509059	NaN
3	D	-1.135632	-0.173215
4	D	-1.135632	0.119209
5	E	NaN	-1.044236

Missing data

Both pandas and SAS have a representation for missing data.

pandas represents missing data with the special float value NaN (not a number). Many of the semantics are the same; for example missing data propagates through numeric operations, and is ignored by default for aggregations.

```
In [1]: outer_join
Out[1]:
   key    value_x    value_y
0   A    0.469112      NaN
1   B   -0.282863   1.212112
2   C   -1.509059      NaN
3   D   -1.135632  -0.173215
4   D   -1.135632   0.119209
5   E        NaN  -1.044236

In [2]: outer_join["value_x"] + outer_join["value_y"]
Out[2]:
0        NaN
1    0.929249
2        NaN
3   -1.308847
4   -1.016424
5        NaN
dtype: float64

In [3]: outer_join["value_x"].sum()
Out[3]: -3.5940742896293765
```

One difference is that missing data cannot be compared to its sentinel value. For example, in SAS you could do this to filter missing values.

```
data outer_join_nulls;
  set outer_join;
  if value_x = .;
run;

data outer_join_no_nulls;
  set outer_join;
  if value_x ^= .;
run;
```

In pandas, `Series.isna()` and `Series.notna()` can be used to filter the rows.

```
In [1]: outer_join[outer_join["value_x"].isna()]
Out[1]:
   key    value_x    value_y
5   E        NaN  -1.044236

In [2]: outer_join[outer_join["value_x"].notna()]
Out[2]:
   key    value_x    value_y
0   A    0.469112      NaN
```

(continues on next page)

(continued from previous page)

```
1  B -0.282863  1.212112
2  C -1.509059      NaN
3  D -1.135632 -0.173215
4  D -1.135632  0.119209
```

pandas provides *a variety of methods to work with missing data*. Here are some examples:

Drop rows with missing values

```
In [3]: outer_join.dropna()
```

```
Out[3]:
```

```
key    value_x    value_y
1    B -0.282863  1.212112
3    D -1.135632 -0.173215
4    D -1.135632  0.119209
```

Forward fill from previous rows

```
In [4]: outer_join.fillna(method="ffill")
```

```
Out[4]:
```

```
key    value_x    value_y
0    A  0.469112      NaN
1    B -0.282863  1.212112
2    C -1.509059  1.212112
3    D -1.135632 -0.173215
4    D -1.135632  0.119209
5    E -1.135632 -1.044236
```

Replace missing values with a specified value

Using the mean:

```
In [1]: outer_join["value_x"].fillna(outer_join["value_x"].mean())
```

```
Out[1]:
```

```
0    0.469112
1   -0.282863
2   -1.509059
3   -1.135632
4   -1.135632
5   -0.718815
Name: value_x, dtype: float64
```

GroupBy

Aggregation

SAS's PROC SUMMARY can be used to group by one or more key variables and compute aggregations on numeric columns.

```
proc summary data=tips nway;
  class sex smoker;
  var total_bill tip;
  output out=tips_summed sum=;
run;
```

pandas provides a flexible groupby mechanism that allows similar aggregations. See the [groupby documentation](#) for more details and examples.

```
In [1]: tips_summed = tips.groupby(["sex", "smoker"])[["total_bill", "tip"]].sum()
```

```
In [2]: tips_summed
```

```
Out[2]:
      total_bill      tip
sex   smoker
Female No        869.68  149.77
      Yes        527.27  96.74
Male   No       1725.75 302.00
      Yes       1217.07 183.07
```

Transformation

In SAS, if the group aggregations need to be used with the original frame, it must be merged back together. For example, to subtract the mean for each observation by smoker group.

```
proc summary data=tips missing nway;
  class smoker;
  var total_bill;
  output out=smoker_means mean(total_bill)=group_bill;
run;

proc sort data=tips;
  by smoker;
run;

data tips;
  merge tips(in=a) smoker_means(in=b);
  by smoker;
  adj_total_bill = total_bill - group_bill;
  if a and b;
run;
```

pandas provides a [Transformation](#) mechanism that allows these type of operations to be succinctly expressed in one operation.

```
In [1]: gb = tips.groupby("smoker")["total_bill"]

In [2]: tips["adj_total_bill"] = tips["total_bill"] - gb.transform("mean")

In [3]: tips
Out[3]:
   total_bill    tip     sex smoker  day    time  size  adj_total_bill
67      1.07  1.00  Female    Yes  Sat  Dinner    1   -17.686344
92      3.75  1.00  Female    Yes  Fri  Dinner    2   -15.006344
111     5.25  1.00  Female     No  Sat  Dinner    1   -11.938278
145     6.35  1.50  Female     No Thur  Lunch    2   -10.838278
135     6.51  1.25  Female     No Thur  Lunch    2   -10.678278
...
182    43.35  3.50    Male    Yes  Sun  Dinner    3    24.593656
156    46.17  5.00    Male     No  Sun  Dinner    6    28.981722
59     46.27  6.73    Male     No  Sat  Dinner    4    29.081722
212    46.33  9.00    Male     No  Sat  Dinner    4    29.141722
170    48.81 10.00    Male    Yes  Sat  Dinner    3    30.053656

[244 rows x 8 columns]
```

By group processing

In addition to aggregation, pandas `groupby` can be used to replicate most other by group processing from SAS. For example, this DATA step reads the data by sex/smoker group and filters to the first entry for each.

```
proc sort data=tips;
  by sex smoker;
run;

data tips_first;
  set tips;
  by sex smoker;
  if FIRST.sex or FIRST.smoker then output;
run;
```

In pandas this would be written as:

```
In [4]: tips.groupby(["sex", "smoker"]).first()
Out[4]:
   total_bill    tip     day    time  size  adj_total_bill
sex   smoker
Female No          5.25  1.00  Sat  Dinner    1   -11.938278
                  1.07  1.00  Sat  Dinner    1   -17.686344
Male   No          5.51  2.00 Thur  Lunch    2   -11.678278
                  5.25  5.15 Sun  Dinner    2   -13.506344
```

Other considerations

Disk vs memory

pandas operates exclusively in memory, where a SAS data set exists on disk. This means that the size of data able to be loaded in pandas is limited by your machine's memory, but also that the operations on that data may be faster.

If out of core processing is needed, one possibility is the `dask.dataframe` library (currently in development) which provides a subset of pandas functionality for an on-disk DataFrame

Data interop

pandas provides a `read_sas()` method that can read SAS data saved in the XPORT or SAS7BDAT binary format.

```
libname xportout xport 'transport-file.xpt';
data xportout.tips;
  set tips(rename=(total_bill=tbill));
  /* xport variable names limited to 6 characters;
run;
```

```
df = pd.read_sas("transport-file.xpt")
df = pd.read_sas("binary-file.sas7bdat")
```

You can also specify the file format directly. By default, pandas will try to infer the file format based on its extension.

```
df = pd.read_sas("transport-file.xpt", format="xport")
df = pd.read_sas("binary-file.sas7bdat", format="sas7bdat")
```

XPORT is a relatively limited format and the parsing of it is not as optimized as some of the other pandas readers. An alternative way to interop data between SAS and pandas is to serialize to csv.

```
# version 0.17, 10M rows

In [8]: %time df = pd.read_sas('big.xpt')
Wall time: 14.6 s

In [9]: %time df = pd.read_csv('big.csv')
Wall time: 4.86 s
```

Comparison with Stata

For potential users coming from [Stata](#) this page is meant to demonstrate how different Stata operations would be performed in pandas.

If you're new to pandas, you might want to first read through [10 Minutes to pandas](#) to familiarize yourself with the library.

As is customary, we import pandas and NumPy as follows:

```
In [1]: import pandas as pd

In [2]: import numpy as np
```

Data structures

General terminology translation

pandas	Stata
DataFrame	data set
column	variable
row	observation
groupby	bysort
NaN	.

DataFrame

A `DataFrame` in pandas is analogous to a Stata data set – a two-dimensional data source with labeled columns that can be of different types. As will be shown in this document, almost any operation that can be applied to a data set in Stata can also be accomplished in pandas.

Series

A `Series` is the data structure that represents one column of a `DataFrame`. Stata doesn't have a separate data structure for a single column, but in general, working with a `Series` is analogous to referencing a column of a data set in Stata.

Index

Every `DataFrame` and `Series` has an `Index` – labels on the *rows* of the data. Stata does not have an exactly analogous concept. In Stata, a data set's rows are essentially unlabeled, other than an implicit integer index that can be accessed with `_n`.

In pandas, if no index is specified, an integer index is also used by default (first row = 0, second row = 1, and so on). While using a labeled `Index` or `MultiIndex` can enable sophisticated analyses and is ultimately an important part of pandas to understand, for this comparison we will essentially ignore the `Index` and just treat the `DataFrame` as a collection of columns. Please see the [indexing documentation](#) for much more on how to use an `Index` effectively.

Copies vs. in place operations

Most pandas operations return copies of the `Series`/`DataFrame`. To make the changes “stick”, you'll need to either assign to a new variable:

```
sorted_df = df.sort_values("col1")
```

or overwrite the original one:

```
df = df.sort_values("col1")
```

Note: You will see an `inplace=True` keyword argument available for some methods:

```
df.sort_values("col1", inplace=True)
```

Its use is discouraged. [More information.](#)

Data input / output

Constructing a DataFrame from values

A Stata data set can be built from specified values by placing the data after an `input` statement and specifying the column names.

```
input x y
1 2
3 4
5 6
end
```

A pandas DataFrame can be constructed in many different ways, but for a small number of values, it is often convenient to specify it as a Python dictionary, where the keys are the column names and the values are the data.

```
In [3]: df = pd.DataFrame({"x": [1, 3, 5], "y": [2, 4, 6]})

In [4]: df
Out[4]:
   x  y
0  1  2
1  3  4
2  5  6
```

Reading external data

Like Stata, pandas provides utilities for reading in data from many formats. The `tips` data set, found within the pandas tests (`csv`) will be used in many of the following examples.

Stata provides `import delimited` to read csv data into a data set in memory. If the `tips.csv` file is in the current working directory, we can import it as follows.

```
import delimited tips.csv
```

The pandas method is `read_csv()`, which works similarly. Additionally, it will automatically download the data set if presented with a url.

```
In [5]: url = (
...:     "https://raw.github.com/pandas-dev"
...:     "/pandas/main/pandas/tests/io/data/csv/tips.csv"
...: )
...:

In [6]: tips = pd.read_csv(url)

In [7]: tips
Out[7]:
   total_bill    tip     sex smoker    day    time    size
```

(continues on next page)

(continued from previous page)

0	16.99	1.01	Female	No	Sun	Dinner	2
1	10.34	1.66	Male	No	Sun	Dinner	3
2	21.01	3.50	Male	No	Sun	Dinner	3
3	23.68	3.31	Male	No	Sun	Dinner	2
4	24.59	3.61	Female	No	Sun	Dinner	4
..
239	29.03	5.92	Male	No	Sat	Dinner	3
240	27.18	2.00	Female	Yes	Sat	Dinner	2
241	22.67	2.00	Male	Yes	Sat	Dinner	2
242	17.82	1.75	Male	No	Sat	Dinner	2
243	18.78	3.00	Female	No	Thur	Dinner	2

[244 rows x 7 columns]

Like `import delimited, read_csv()` can take a number of parameters to specify how the data should be parsed. For example, if the data were instead tab delimited, did not have column names, and existed in the current working directory, the pandas command would be:

```
tips = pd.read_csv("tips.csv", sep="\t", header=None)

# alternatively, read_table is an alias to read_csv with tab delimiter
tips = pd.read_table("tips.csv", header=None)
```

pandas can also read Stata data sets in `.dta` format with the `read_stata()` function.

```
df = pd.read_stata("data.dta")
```

In addition to text/csv and Stata files, pandas supports a variety of other data formats such as Excel, SAS, HDF5, Parquet, and SQL databases. These are all read via a `pd.read_*` function. See the [IO documentation](#) for more details.

Limiting output

By default, pandas will truncate output of large DataFrames to show the first and last rows. This can be overridden by [changing the pandas options](#), or using `DataFrame.head()` or `DataFrame.tail()`.

```
In [8]: tips.head(5)
Out[8]:
   total_bill    tip      sex smoker  day   time  size
0        16.99  1.01  Female    No  Sun  Dinner    2
1        10.34  1.66    Male    No  Sun  Dinner    3
2        21.01  3.50    Male    No  Sun  Dinner    3
3        23.68  3.31    Male    No  Sun  Dinner    2
4        24.59  3.61  Female    No  Sun  Dinner    4
```

The equivalent in Stata would be:

```
list in 1/5
```

Exporting data

The inverse of `import delimited` in Stata is `export delimited`

```
export delimited tips2.csv
```

Similarly in pandas, the opposite of `read_csv` is `DataFrame.to_csv()`.

```
tips.to_csv("tips2.csv")
```

pandas can also export to Stata file format with the `DataFrame.to_stata()` method.

```
tips.to_stata("tips2.dta")
```

Data operations

Operations on columns

In Stata, arbitrary math expressions can be used with the `generate` and `replace` commands on new or existing columns. The `drop` command drops the column from the data set.

```
replace total_bill = total_bill - 2
generate new_bill = total_bill / 2
drop new_bill
```

pandas provides vectorized operations by specifying the individual Series in the DataFrame. New columns can be assigned in the same way. The `DataFrame.drop()` method drops a column from the DataFrame.

```
In [9]: tips["total_bill"] = tips["total_bill"] - 2
```

```
In [10]: tips["new_bill"] = tips["total_bill"] / 2
```

```
In [11]: tips
```

```
Out[11]:
```

	total_bill	tip	sex	smoker	day	time	size	new_bill
0	14.99	1.01	Female	No	Sun	Dinner	2	7.495
1	8.34	1.66	Male	No	Sun	Dinner	3	4.170
2	19.01	3.50	Male	No	Sun	Dinner	3	9.505
3	21.68	3.31	Male	No	Sun	Dinner	2	10.840
4	22.59	3.61	Female	No	Sun	Dinner	4	11.295
..
239	27.03	5.92	Male	No	Sat	Dinner	3	13.515
240	25.18	2.00	Female	Yes	Sat	Dinner	2	12.590
241	20.67	2.00	Male	Yes	Sat	Dinner	2	10.335
242	15.82	1.75	Male	No	Sat	Dinner	2	7.910
243	16.78	3.00	Female	No	Thur	Dinner	2	8.390

```
[244 rows x 8 columns]
```

```
In [12]: tips = tips.drop("new_bill", axis=1)
```

Filtering

Filtering in Stata is done with an `if` clause on one or more columns.

```
list if total_bill > 10
```

DataFrames can be filtered in multiple ways; the most intuitive of which is using *boolean indexing*.

```
In [13]: tips[tips["total_bill"] > 10]
```

```
Out[13]:
```

	total_bill	tip	sex	smoker	day	time	size
0	14.99	1.01	Female	No	Sun	Dinner	2
2	19.01	3.50	Male	No	Sun	Dinner	3
3	21.68	3.31	Male	No	Sun	Dinner	2
4	22.59	3.61	Female	No	Sun	Dinner	4
5	23.29	4.71	Male	No	Sun	Dinner	4
..
239	27.03	5.92	Male	No	Sat	Dinner	3
240	25.18	2.00	Female	Yes	Sat	Dinner	2
241	20.67	2.00	Male	Yes	Sat	Dinner	2
242	15.82	1.75	Male	No	Sat	Dinner	2
243	16.78	3.00	Female	No	Thur	Dinner	2

[204 rows x 7 columns]

The above statement is simply passing a Series of True/False objects to the DataFrame, returning all rows with True.

```
In [14]: is_dinner = tips["time"] == "Dinner"
```

```
In [15]: is_dinner
```

```
Out[15]:
```

0	True
1	True
2	True
3	True
4	True
..	..
239	True
240	True
241	True
242	True
243	True

Name: time, Length: 244, dtype: bool

```
In [16]: is_dinner.value_counts()
```

```
Out[16]:
```

True	176
False	68

Name: time, dtype: int64

```
In [17]: tips[is_dinner]
```

```
Out[17]:
```

(continues on next page)

(continued from previous page)

	total_bill	tip	sex	smoker	day	time	size
0	14.99	1.01	Female	No	Sun	Dinner	2
1	8.34	1.66	Male	No	Sun	Dinner	3
2	19.01	3.50	Male	No	Sun	Dinner	3
3	21.68	3.31	Male	No	Sun	Dinner	2
4	22.59	3.61	Female	No	Sun	Dinner	4
..
239	27.03	5.92	Male	No	Sat	Dinner	3
240	25.18	2.00	Female	Yes	Sat	Dinner	2
241	20.67	2.00	Male	Yes	Sat	Dinner	2
242	15.82	1.75	Male	No	Sat	Dinner	2
243	16.78	3.00	Female	No	Thur	Dinner	2

[176 rows x 7 columns]

If/then logic

In Stata, an if clause can also be used to create new columns.

```
generate bucket = "low" if total_bill < 10
replace bucket = "high" if total_bill >= 10
```

The same operation in pandas can be accomplished using the where method from numpy.

```
In [18]: tips["bucket"] = np.where(tips["total_bill"] < 10, "low", "high")
```

```
In [19]: tips
```

```
Out[19]:
```

	total_bill	tip	sex	smoker	day	time	size	bucket
0	14.99	1.01	Female	No	Sun	Dinner	2	high
1	8.34	1.66	Male	No	Sun	Dinner	3	low
2	19.01	3.50	Male	No	Sun	Dinner	3	high
3	21.68	3.31	Male	No	Sun	Dinner	2	high
4	22.59	3.61	Female	No	Sun	Dinner	4	high
..
239	27.03	5.92	Male	No	Sat	Dinner	3	high
240	25.18	2.00	Female	Yes	Sat	Dinner	2	high
241	20.67	2.00	Male	Yes	Sat	Dinner	2	high
242	15.82	1.75	Male	No	Sat	Dinner	2	high
243	16.78	3.00	Female	No	Thur	Dinner	2	high

[244 rows x 8 columns]

Date functionality

Stata provides a variety of functions to do operations on date/datetime columns.

```
generate date1 = mdy(1, 15, 2013)
generate date2 = date("Feb152015", "MDY")

generate date1_year = year(date1)
generate date2_month = month(date2)

* shift date to beginning of next month
generate date1_next = mdy(month(date1) + 1, 1, year(date1)) if month(date1) != 12
replace date1_next = mdy(1, 1, year(date1) + 1) if month(date1) == 12
generate months_between = mofd(date2) - mofd(date1)

list date1 date2 date1_year date2_month date1_next months_between
```

The equivalent pandas operations are shown below. In addition to these functions, pandas supports other Time Series features not available in Stata (such as time zone handling and custom offsets) – see the [timeseries documentation](#) for more details.

```
In [20]: tips["date1"] = pd.Timestamp("2013-01-15")
In [21]: tips["date2"] = pd.Timestamp("2015-02-15")
In [22]: tips["date1_year"] = tips["date1"].dt.year
In [23]: tips["date2_month"] = tips["date2"].dt.month
In [24]: tips["date1_next"] = tips["date1"] + pd.offsets.MonthBegin()
In [25]: tips["months_between"] = tips["date2"].dt.to_period("M") - tips[
.....:     "date1"
.....: ].dt.to_period("M")
.....:

In [26]: tips[
.....:     ["date1", "date2", "date1_year", "date2_month", "date1_next", "months_
->between"]
.....: ]
.....:
Out[26]:
   date1      date2  date1_year  date2_month date1_next    months_between
0  2013-01-15 2015-02-15      2013            2 2013-02-01 <25 * MonthEnds>

```

Selection of columns

Stata provides keywords to select, drop, and rename columns.

```
keep sex total_bill tip  
drop sex  
rename total_bill total_bill_2
```

The same operations are expressed in pandas below.

Keep certain columns

```
In [27]: tips[["sex", "total_bill", "tip"]]  
Out[27]:  
       sex  total_bill  tip  
0    Female     14.99  1.01  
1     Male      8.34  1.66  
2     Male     19.01  3.50  
3     Male     21.68  3.31  
4    Female     22.59  3.61  
..    ...     ...  ...  
239    Male     27.03  5.92  
240  Female     25.18  2.00  
241    Male     20.67  2.00  
242    Male     15.82  1.75  
243  Female     16.78  3.00  
  
[244 rows x 3 columns]
```

Drop a column

```
In [28]: tips.drop("sex", axis=1)  
Out[28]:  
      total_bill  tip  smoker  day  time  size  
0        14.99  1.01     No  Sun Dinner    2  
1         8.34  1.66     No  Sun Dinner    3  
2        19.01  3.50     No  Sun Dinner    3  
3        21.68  3.31     No  Sun Dinner    2  
4        22.59  3.61     No  Sun Dinner    4  
..        ...  ...     ...  ...  ...  ...  
239      27.03  5.92     No  Sat Dinner    3  
240      25.18  2.00    Yes  Sat Dinner    2
```

(continues on next page)

(continued from previous page)

```
241    20.67  2.00    Yes   Sat  Dinner    2
242    15.82  1.75    No    Sat  Dinner    2
243    16.78  3.00    No   Thur  Dinner    2
```

[244 rows x 6 columns]

Rename a column

```
In [29]: tips.rename(columns={"total_bill": "total_bill_2"})
```

```
Out[29]:
```

	total_bill_2	tip	sex	smoker	day	time	size
0	14.99	1.01	Female	No	Sun	Dinner	2
1	8.34	1.66	Male	No	Sun	Dinner	3
2	19.01	3.50	Male	No	Sun	Dinner	3
3	21.68	3.31	Male	No	Sun	Dinner	2
4	22.59	3.61	Female	No	Sun	Dinner	4
..
239	27.03	5.92	Male	No	Sat	Dinner	3
240	25.18	2.00	Female	Yes	Sat	Dinner	2
241	20.67	2.00	Male	Yes	Sat	Dinner	2
242	15.82	1.75	Male	No	Sat	Dinner	2
243	16.78	3.00	Female	No	Thur	Dinner	2

[244 rows x 7 columns]

Sorting by values

Sorting in Stata is accomplished via `sort`

```
sort sex total_bill
```

pandas has a `DataFrame.sort_values()` method, which takes a list of columns to sort by.

```
In [30]: tips = tips.sort_values(["sex", "total_bill"])
```

```
In [31]: tips
```

```
Out[31]:
```

	total_bill	tip	sex	smoker	day	time	size
67	1.07	1.00	Female	Yes	Sat	Dinner	1
92	3.75	1.00	Female	Yes	Fri	Dinner	2
111	5.25	1.00	Female	No	Sat	Dinner	1
145	6.35	1.50	Female	No	Thur	Lunch	2
135	6.51	1.25	Female	No	Thur	Lunch	2
..
182	43.35	3.50	Male	Yes	Sun	Dinner	3
156	46.17	5.00	Male	No	Sun	Dinner	6
59	46.27	6.73	Male	No	Sat	Dinner	4
212	46.33	9.00	Male	No	Sat	Dinner	4
170	48.81	10.00	Male	Yes	Sat	Dinner	3

(continues on next page)

(continued from previous page)

```
[244 rows x 7 columns]
```

String processing

Finding length of string

Stata determines the length of a character string with the `strlen()` and `ustrlen()` functions for ASCII and Unicode strings, respectively.

```
generate strlen_time = strlen(time)
generate ustrlen_time = ustrlen(time)
```

You can find the length of a character string with `Series.str.len()`. In Python 3, all strings are Unicode strings. `len` includes trailing blanks. Use `len` and `rstrip` to exclude trailing blanks.

```
In [32]: tips["time"].str.len()
Out[32]:
67      6
92      6
111     6
145     5
135     5
..
182     6
156     6
59      6
212     6
170     6
Name: time, Length: 244, dtype: int64
```

```
In [33]: tips["time"].str.rstrip().str.len()
Out[33]:
67      6
92      6
111     6
145     5
135     5
..
182     6
156     6
59      6
212     6
170     6
Name: time, Length: 244, dtype: int64
```

Finding position of substring

Stata determines the position of a character in a string with the `strpos()` function. This takes the string defined by the first argument and searches for the first position of the substring you supply as the second argument.

```
generate str_position = strpos(sex, "ale")
```

You can find the position of a character in a column of strings with the `Series.str.find()` method. `find` searches for the first position of the substring. If the substring is found, the method returns its position. If not found, it returns -1. Keep in mind that Python indexes are zero-based.

```
In [34]: tips["sex"].str.find("ale")
```

```
Out[34]:
```

```
67      3
92      3
111     3
145     3
135     3
...
182      1
156      1
59       1
212     1
170     1
Name: sex, Length: 244, dtype: int64
```

Extracting substring by position

Stata extracts a substring from a string based on its position with the `substr()` function.

```
generate short_sex = substr(sex, 1, 1)
```

With pandas you can use [] notation to extract a substring from a string by position locations. Keep in mind that Python indexes are zero-based.

```
In [35]: tips["sex"].str[0:1]
```

```
Out[35]:
```

```
67      F
92      F
111     F
145     F
135     F
...
182      M
156      M
59       M
212     M
170     M
Name: sex, Length: 244, dtype: object
```

Extracting nth word

The Stata `word()` function returns the nth word from a string. The first argument is the string you want to parse and the second argument specifies which word you want to extract.

```
clear  
input str20 string  
"John Smith"  
"Jane Cook"  
end  
  
generate first_name = word(name, 1)  
generate last_name = word(name, -1)
```

The simplest way to extract words in pandas is to split the strings by spaces, then reference the word by index. Note there are more powerful approaches should you need them.

```
In [36]: firstlast = pd.DataFrame({"String": ["John Smith", "Jane Cook"]})  
  
In [37]: firstlast["First_Name"] = firstlast["String"].str.split(" ", expand=True)[0]  
  
In [38]: firstlast["Last_Name"] = firstlast["String"].str.rsplit(" ", expand=True)[1]  
  
In [39]: firstlast  
Out[39]:  
      String First_Name Last_Name  
0   John Smith       John     Smith  
1   Jane Cook        Jane     Cook
```

Changing case

The Stata `strupper()`, `strlower()`, `strproper()`, `ustrupper()`, `ustrlower()`, and `ustrtitle()` functions change the case of ASCII and Unicode strings, respectively.

```
clear  
input str20 string  
"John Smith"  
"Jane Cook"  
end  
  
generate upper = strupper(string)  
generate lower = strlower(string)  
generate title = strproper(string)  
list
```

The equivalent pandas methods are `Series.str.upper()`, `Series.str.lower()`, and `Series.str.title()`.

```
In [40]: firstlast = pd.DataFrame({"string": ["John Smith", "Jane Cook"]})  
  
In [41]: firstlast["upper"] = firstlast["string"].str.upper()  
  
In [42]: firstlast["lower"] = firstlast["string"].str.lower()
```

(continues on next page)

(continued from previous page)

```
In [43]: firstlast["title"] = firstlast["string"].str.title()
```

```
In [44]: firstlast
```

```
Out[44]:
```

	string	upper	lower	title
0	John Smith	JOHN SMITH	john smith	John Smith
1	Jane Cook	JANE COOK	jane cook	Jane Cook

Merging

The following tables will be used in the merge examples:

```
In [45]: df1 = pd.DataFrame({"key": ["A", "B", "C", "D"], "value": np.random.randn(4)})
```

```
In [46]: df1
```

```
Out[46]:
```

	key	value
0	A	0.469112
1	B	-0.282863
2	C	-1.509059
3	D	-1.135632

```
In [47]: df2 = pd.DataFrame({"key": ["B", "D", "D", "E"], "value": np.random.randn(4)})
```

```
In [48]: df2
```

```
Out[48]:
```

	key	value
0	B	1.212112
1	D	-0.173215
2	D	0.119209
3	E	-1.044236

In Stata, to perform a merge, one data set must be in memory and the other must be referenced as a file name on disk. In contrast, Python must have both `DataFrames` already in memory.

By default, Stata performs an outer join, where all observations from both data sets are left in memory after the merge. One can keep only observations from the initial data set, the merged data set, or the intersection of the two by using the values created in the `_merge` variable.

```
* First create df2 and save to disk
clear
input str1 key
B
D
D
E
end
generate value = rnormal()
save df2.dta
```

(continues on next page)

(continued from previous page)

```
* Now create df1 in memory
clear
input str1 key
A
B
C
D
end
generate value = rnormal()

preserve

* Left join
merge 1:n key using df2.dta
keep if _merge == 1

* Right join
restore, preserve
merge 1:n key using df2.dta
keep if _merge == 2

* Inner join
restore, preserve
merge 1:n key using df2.dta
keep if _merge == 3

* Outer join
restore
merge 1:n key using df2.dta
```

pandas DataFrames have a `merge()` method, which provides similar functionality. The data does not have to be sorted ahead of time, and different join types are accomplished via the `how` keyword.

```
In [49]: inner_join = df1.merge(df2, on=["key"], how="inner")
```

```
In [50]: inner_join
```

```
Out[50]:
```

	key	value_x	value_y
0	B	-0.282863	1.212112
1	D	-1.135632	-0.173215
2	D	-1.135632	0.119209

```
In [51]: left_join = df1.merge(df2, on=["key"], how="left")
```

```
In [52]: left_join
```

```
Out[52]:
```

	key	value_x	value_y
0	A	0.469112	NaN
1	B	-0.282863	1.212112
2	C	-1.509059	NaN
3	D	-1.135632	-0.173215
4	D	-1.135632	0.119209

(continues on next page)

(continued from previous page)

```
In [53]: right_join = df1.merge(df2, on=["key"], how="right")
```

```
In [54]: right_join
```

```
Out[54]:
```

	key	value_x	value_y
0	B	-0.282863	1.212112
1	D	-1.135632	-0.173215
2	D	-1.135632	0.119209
3	E	NaN	-1.044236

```
In [55]: outer_join = df1.merge(df2, on=["key"], how="outer")
```

```
In [56]: outer_join
```

```
Out[56]:
```

	key	value_x	value_y
0	A	0.469112	NaN
1	B	-0.282863	1.212112
2	C	-1.509059	NaN
3	D	-1.135632	-0.173215
4	D	-1.135632	0.119209
5	E	NaN	-1.044236

Missing data

Both pandas and Stata have a representation for missing data.

pandas represents missing data with the special float value NaN (not a number). Many of the semantics are the same; for example missing data propagates through numeric operations, and is ignored by default for aggregations.

```
In [57]: outer_join
```

```
Out[57]:
```

	key	value_x	value_y
0	A	0.469112	NaN
1	B	-0.282863	1.212112
2	C	-1.509059	NaN
3	D	-1.135632	-0.173215
4	D	-1.135632	0.119209
5	E	NaN	-1.044236

```
In [58]: outer_join["value_x"] + outer_join["value_y"]
```

```
Out[58]:
```

0	NaN
1	0.929249
2	NaN
3	-1.308847
4	-1.016424
5	NaN

dtype: float64

```
In [59]: outer_join["value_x"].sum()
```

(continues on next page)

(continued from previous page)

Out[59]: -3.5940742896293765

One difference is that missing data cannot be compared to its sentinel value. For example, in Stata you could do this to filter missing values.

```
* Keep missing values
list if value_x == .
* Keep non-missing values
list if value_x != .
```

In pandas, `Series.isna()` and `Series.notna()` can be used to filter the rows.

In [60]: outer_join[outer_join["value_x"].isna()]**Out[60]:**

```
key    value_x    value_y
5      E        NaN -1.044236
```

In [61]: outer_join[outer_join["value_x"].notna()]**Out[61]:**

```
key    value_x    value_y
0      A  0.469112      NaN
1      B -0.282863  1.212112
2      C -1.509059      NaN
3      D -1.135632 -0.173215
4      D -1.135632  0.119209
```

pandas provides *a variety of methods to work with missing data*. Here are some examples:

Drop rows with missing values

In [62]: outer_join.dropna()**Out[62]:**

```
key    value_x    value_y
1      B -0.282863  1.212112
3      D -1.135632 -0.173215
4      D -1.135632  0.119209
```

Forward fill from previous rows

In [63]: outer_join.fillna(method="ffill")**Out[63]:**

```
key    value_x    value_y
0      A  0.469112      NaN
1      B -0.282863  1.212112
2      C -1.509059  1.212112
3      D -1.135632 -0.173215
4      D -1.135632  0.119209
5      E -1.135632 -1.044236
```

Replace missing values with a specified value

Using the mean:

```
In [64]: outer_join["value_x"].fillna(outer_join["value_x"].mean())
Out[64]:
0    0.469112
1   -0.282863
2   -1.509059
3   -1.135632
4   -1.135632
5   -0.718815
Name: value_x, dtype: float64
```

GroupBy

Aggregation

Stata's collapse can be used to group by one or more key variables and compute aggregations on numeric columns.

```
collapse (sum) total_bill tip, by(sex smoker)
```

pandas provides a flexible groupby mechanism that allows similar aggregations. See the [groupby documentation](#) for more details and examples.

```
In [65]: tips_summed = tips.groupby(["sex", "smoker"])[["total_bill", "tip"]].sum()

In [66]: tips_summed
Out[66]:
      total_bill      tip
sex   smoker
Female No        869.68  149.77
      Yes        527.27  96.74
Male   No       1725.75  302.00
      Yes       1217.07  183.07
```

Transformation

In Stata, if the group aggregations need to be used with the original data set, one would usually use bysort with egen(). For example, to subtract the mean for each observation by smoker group.

```
bysort sex smoker: egen group_bill = mean(total_bill)
generate adj_total_bill = total_bill - group_bill
```

pandas provides a *Transformation* mechanism that allows these type of operations to be succinctly expressed in one operation.

```
In [67]: gb = tips.groupby("smoker")["total_bill"]
In [68]: tips["adj_total_bill"] = tips["total_bill"] - gb.transform("mean")
```

(continues on next page)

(continued from previous page)

```
In [69]: tips
Out[69]:
   total_bill    tip      sex smoker  day    time    size  adj_total_bill
67       1.07  1.00  Female    Yes  Sat  Dinner     1   -17.686344
92       3.75  1.00  Female    Yes  Fri  Dinner     2   -15.006344
111      5.25  1.00  Female    No   Sat  Dinner     1   -11.938278
145      6.35  1.50  Female    No  Thur  Lunch     2   -10.838278
135      6.51  1.25  Female    No  Thur  Lunch     2   -10.678278
...
182     43.35  3.50   Male    Yes  Sun  Dinner     3    24.593656
156     46.17  5.00   Male    No   Sun  Dinner     6    28.981722
59      46.27  6.73   Male    No   Sat  Dinner     4    29.081722
212     46.33  9.00   Male    No   Sat  Dinner     4    29.141722
170     48.81 10.00   Male    Yes  Sat  Dinner     3    30.053656
```

[244 rows x 8 columns]

By group processing

In addition to aggregation, pandas groupby can be used to replicate most other bysort processing from Stata. For example, the following example lists the first observation in the current sort order by sex/smoker group.

```
bysort sex smoker: list if _n == 1
```

In pandas this would be written as:

```
In [70]: tips.groupby(["sex", "smoker"]).first()
Out[70]:
   total_bill    tip      day    time    size  adj_total_bill
sex   smoker
Female  No        5.25  1.00  Sat  Dinner     1   -11.938278
                  1.07  1.00  Sat  Dinner     1   -17.686344
Male   No        5.51  2.00  Thur  Lunch     2   -11.678278
                  5.25  5.15  Sun  Dinner     2   -13.506344
```

Other considerations

Disk vs memory

pandas and Stata both operate exclusively in memory. This means that the size of data able to be loaded in pandas is limited by your machine's memory. If out of core processing is needed, one possibility is the `dask.dataframe` library, which provides a subset of pandas functionality for an on-disk `DataFrame`.

1.4.5 Community tutorials

This is a guide to many pandas tutorials by the community, geared mainly for new users.

pandas cookbook by Julia Evans

The goal of this 2015 cookbook (by Julia Evans) is to give you some concrete examples for getting started with pandas. These are examples with real-world data, and all the bugs and weirdness that entails. For the table of contents, see the [pandas-cookbook GitHub repository](#).

pandas workshop by Stefanie Molin

An introductory workshop by Stefanie Molin designed to quickly get you up to speed with pandas using real-world datasets. It covers getting started with pandas, data wrangling, and data visualization (with some exposure to matplotlib and seaborn). The [pandas-workshop GitHub repository](#) features detailed environment setup instructions (including a Binder environment), slides and notebooks for following along, and exercises to practice the concepts. There is also a lab with new exercises on a dataset not covered in the workshop for additional practice.

Learn pandas by Hernan Rojas

A set of lesson for new pandas users: <https://bitbucket.org/hrojas/learn-pandas>

Practical data analysis with Python

This [guide](#) is an introduction to the data analysis process using the Python data ecosystem and an interesting open dataset. There are four sections covering selected topics as [munging data](#), [aggregating data](#), [visualizing data](#) and [time series](#).

Exercises for new users

Practice your skills with real data sets and exercises. For more resources, please visit the main [repository](#).

Modern pandas

Tutorial series written in 2016 by Tom Augspurger. The source may be found in the GitHub repository [TomAugspurger/effective-pandas](#).

- Introduction Into Pandas (2016) (1:28) [GitHub repo](#)
- Pandas: .head() to .tail() (2016) (1:26) [GitHub repo](#)
- Data analysis in Python with pandas (2016-2018) [GitHub repo](#) and [Jupyter Notebook](#)
- Best practices with pandas (2018) [GitHub repo](#) and [Jupyter Notebook](#)

Various tutorials

- Wes McKinney's (pandas BDFL) blog
- Statistical analysis made easy in Python with SciPy and pandas DataFrames, by Randal Olson
- Statistical Data Analysis in Python, tutorial videos, by Christopher Fonnesbeck from SciPy 2013
- Financial analysis in Python, by Thomas Wiecki
- Intro to pandas data structures, by Greg Reda
- Pandas and Python: Top 10, by Manish Amde
- Pandas DataFrames Tutorial, by Karlijn Willems
- A concise tutorial with real life examples

USER GUIDE

The User Guide covers all of pandas by topic area. Each of the subsections introduces a topic (such as “working with missing data”), and discusses how pandas approaches the problem, with many examples throughout.

Users brand-new to pandas should start with 10min.

For a high level summary of the pandas fundamentals, see [Intro to data structures](#) and [Essential basic functionality](#).

Further information on any specific method can be obtained in the [API reference](#). {{ header }}

2.1 10 minutes to pandas

This is a short introduction to pandas, geared mainly for new users. You can see more complex recipes in the [Cookbook](#).

Customarily, we import as follows:

```
In [1]: import numpy as np
```

```
In [2]: import pandas as pd
```

2.1.1 Object creation

See the [Intro to data structures section](#).

Creating a Series by passing a list of values, letting pandas create a default integer index:

```
In [3]: s = pd.Series([1, 3, 5, np.nan, 6, 8])
```

```
In [4]: s
```

```
Out[4]:
```

```
0    1.0
1    3.0
2    5.0
3    NaN
4    6.0
5    8.0
dtype: float64
```

Creating a DataFrame by passing a NumPy array, with a datetime index and labeled columns:

```
In [5]: dates = pd.date_range("20130101", periods=6)

In [6]: dates
Out[6]:
DatetimeIndex(['2013-01-01', '2013-01-02', '2013-01-03', '2013-01-04',
               '2013-01-05', '2013-01-06'],
              dtype='datetime64[ns]', freq='D')

In [7]: df = pd.DataFrame(np.random.randn(6, 4), index=dates, columns=list("ABCD"))

In [8]: df
Out[8]:
          A         B         C         D
2013-01-01 -1.325591 -0.336537  0.401489  0.752909
2013-01-02 -0.942121 -0.758401 -0.052704  0.282167
2013-01-03 -0.733393 -0.335276 -2.004442  0.363065
2013-01-04  0.770212 -1.936564 -0.065106 -1.720420
2013-01-05 -0.128739  0.040554  0.514148  1.588288
2013-01-06 -0.486114  0.557386 -0.476266  1.107157
```

Creating a DataFrame by passing a dictionary of objects that can be converted into a series-like structure:

```
In [9]: df2 = pd.DataFrame(
...:     {
...:         "A": 1.0,
...:         "B": pd.Timestamp("20130102"),
...:         "C": pd.Series(1, index=list(range(4)), dtype="float32"),
...:         "D": np.array([3] * 4, dtype="int32"),
...:         "E": pd.Categorical(["test", "train", "test", "train"]),
...:         "F": "foo",
...:     }
...: )

In [10]: df2
Out[10]:
          A         B    C    D      E    F
0  1.0 2013-01-02  1.0  3  test  foo
1  1.0 2013-01-02  1.0  3  train  foo
2  1.0 2013-01-02  1.0  3  test  foo
3  1.0 2013-01-02  1.0  3  train  foo
```

The columns of the resulting DataFrame have different *dtypes*:

```
In [11]: df2.dtypes
Out[11]:
A           float64
B    datetime64[ns]
C           float32
D           int32
E        category
F            object
dtype: object
```

If you're using IPython, tab completion for column names (as well as public attributes) is automatically enabled. Here's a subset of the attributes that will be completed:

```
In [12]: df2.<TAB> # noqa: E225, E999
df2.A          df2.bool
df2.abs        df2.boxplot
df2.add         df2.C
df2.add_prefix df2.clip
df2.add_suffix df2.columns
df2.align       df2.copy
df2.all         df2.count
df2.any         df2.combine
df2.append     df2.D
df2.apply       df2.describe
df2.applymap   df2.diff
df2.B          df2.duplicated
```

As you can see, the columns A, B, C, and D are automatically tab completed. E and F are there as well; the rest of the attributes have been truncated for brevity.

2.1.2 Viewing data

See the [Basics section](#).

Here is how to view the top and bottom rows of the frame:

```
In [13]: df.head()
Out[13]:
           A         B         C         D
2013-01-01 -1.325591 -0.336537  0.401489  0.752909
2013-01-02 -0.942121 -0.758401 -0.052704  0.282167
2013-01-03 -0.733393 -0.335276 -2.004442  0.363065
2013-01-04  0.770212 -1.936564 -0.065106 -1.720420
2013-01-05 -0.128739  0.040554  0.514148  1.588288

In [14]: df.tail(3)
Out[14]:
           A         B         C         D
2013-01-04  0.770212 -1.936564 -0.065106 -1.720420
2013-01-05 -0.128739  0.040554  0.514148  1.588288
2013-01-06 -0.486114  0.557386 -0.476266  1.107157
```

Display the index, columns:

```
In [15]: df.index
Out[15]:
DatetimeIndex(['2013-01-01', '2013-01-02', '2013-01-03', '2013-01-04',
               '2013-01-05', '2013-01-06'],
              dtype='datetime64[ns]', freq='D')

In [16]: df.columns
Out[16]: Index(['A', 'B', 'C', 'D'], dtype='object')
```

`DataFrame.to_numpy()` gives a NumPy representation of the underlying data. Note that this can be an expensive

operation when your DataFrame has columns with different data types, which comes down to a fundamental difference between pandas and NumPy: **NumPy arrays have one dtype for the entire array, while pandas DataFrames have one dtype per column.** When you call DataFrame.to_numpy(), pandas will find the NumPy dtype that can hold *all* of the dtypes in the DataFrame. This may end up being object, which requires casting every value to a Python object.

For df, our DataFrame of all floating-point values, DataFrame.to_numpy() is fast and doesn't require copying data:

```
In [17]: df.to_numpy()
Out[17]:
array([[-1.32559115, -0.33653728,  0.40148882,  0.75290939],
       [-0.94212136, -0.75840071, -0.05270426,  0.2821667 ],
       [-0.73339346, -0.33527577, -2.00444171,  0.36306547],
       [ 0.77021181, -1.93656374, -0.06510639, -1.72042006],
       [-0.12873947,  0.04055377,  0.51414829,  1.58828791],
       [-0.48611421,  0.55738613, -0.47626626,  1.10715709]])
```

For df2, the DataFrame with multiple dtypes, DataFrame.to_numpy() is relatively expensive:

```
In [18]: df2.to_numpy()
Out[18]:
array([[1.0, Timestamp('2013-01-02 00:00:00'), 1.0, 3, 'test', 'foo'],
       [1.0, Timestamp('2013-01-02 00:00:00'), 1.0, 3, 'train', 'foo'],
       [1.0, Timestamp('2013-01-02 00:00:00'), 1.0, 3, 'test', 'foo'],
       [1.0, Timestamp('2013-01-02 00:00:00'), 1.0, 3, 'train', 'foo']],
      dtype=object)
```

Note: DataFrame.to_numpy() does *not* include the index or column labels in the output.

describe() shows a quick statistic summary of your data:

```
In [19]: df.describe()
Out[19]:
          A            B            C            D
count  6.000000  6.000000  6.000000  6.000000
mean  -0.474291 -0.461473 -0.280480  0.395528
std   0.731990  0.846841  0.917078  1.144374
min  -1.325591 -1.936564 -2.004442 -1.720420
25%  -0.889939 -0.652935 -0.373476  0.302391
50%  -0.609754 -0.335907 -0.058905  0.557987
75%  -0.218083 -0.053404  0.287941  1.018595
max   0.770212  0.557386  0.514148  1.588288
```

Transposing your data:

```
In [20]: df.T
Out[20]:
           2013-01-01  2013-01-02  2013-01-03  2013-01-04  2013-01-05  2013-01-06
A  -1.325591  -0.942121  -0.733393  0.770212  -0.128739  -0.486114
B  -0.336537  -0.758401  -0.335276  -1.936564  0.040554  0.557386
C  0.401489  -0.052704  -2.004442  -0.065106  0.514148  -0.476266
D  0.752909  0.282167  0.363065  -1.720420  1.588288  1.107157
```

Sorting by an axis:

```
In [21]: df.sort_index(axis=1, ascending=False)
Out[21]:
          D         C         B         A
2013-01-01  0.752909  0.401489 -0.336537 -1.325591
2013-01-02  0.282167 -0.052704 -0.758401 -0.942121
2013-01-03  0.363065 -2.004442 -0.335276 -0.733393
2013-01-04 -1.720420 -0.065106 -1.936564  0.770212
2013-01-05  1.588288  0.514148  0.040554 -0.128739
2013-01-06  1.107157 -0.476266  0.557386 -0.486114
```

Sorting by values:

```
In [22]: df.sort_values(by="B")
Out[22]:
          A         B         C         D
2013-01-04  0.770212 -1.936564 -0.065106 -1.720420
2013-01-02 -0.942121 -0.758401 -0.052704  0.282167
2013-01-01 -1.325591 -0.336537  0.401489  0.752909
2013-01-03 -0.733393 -0.335276 -2.004442  0.363065
2013-01-05 -0.128739  0.040554  0.514148  1.588288
2013-01-06 -0.486114  0.557386 -0.476266  1.107157
```

2.1.3 Selection

Note: While standard Python / NumPy expressions for selecting and setting are intuitive and come in handy for interactive work, for production code, we recommend the optimized pandas data access methods, `.at`, `.iat`, `.loc` and `.iloc`.

See the indexing documentation [Indexing and Selecting Data](#) and [MultiIndex / Advanced Indexing](#).

Getting

Selecting a single column, which yields a `Series`, equivalent to `df.A`:

```
In [23]: df["A"]
Out[23]:
2013-01-01    -1.325591
2013-01-02    -0.942121
2013-01-03    -0.733393
2013-01-04     0.770212
2013-01-05    -0.128739
2013-01-06    -0.486114
Freq: D, Name: A, dtype: float64
```

Selecting via `[]`, which slices the rows:

```
In [24]: df[0:3]
Out[24]:
          A         B         C         D
2013-01-01 -1.325591 -0.336537  0.401489  0.752909
```

(continues on next page)

(continued from previous page)

```
2013-01-02 -0.942121 -0.758401 -0.052704  0.282167
2013-01-03 -0.733393 -0.335276 -2.004442  0.363065
```

In [25]: df["20130102":"20130104"]

Out[25]:

	A	B	C	D
2013-01-02	-0.942121	-0.758401	-0.052704	0.282167
2013-01-03	-0.733393	-0.335276	-2.004442	0.363065
2013-01-04	0.770212	-1.936564	-0.065106	-1.720420

Selection by label

See more in *Selection by Label*.

For getting a cross section using a label:

In [26]: df.loc[dates[0]]

Out[26]:

A	-1.325591
B	-0.336537
C	0.401489
D	0.752909
Name:	2013-01-01 00:00:00, dtype: float64

Selecting on a multi-axis by label:

In [27]: df.loc[:, ["A", "B"]]

Out[27]:

	A	B
2013-01-01	-1.325591	-0.336537
2013-01-02	-0.942121	-0.758401
2013-01-03	-0.733393	-0.335276
2013-01-04	0.770212	-1.936564
2013-01-05	-0.128739	0.040554
2013-01-06	-0.486114	0.557386

Showing label slicing, both endpoints are *included*:

In [28]: df.loc["20130102":"20130104", ["A", "B"]]

Out[28]:

	A	B
2013-01-02	-0.942121	-0.758401
2013-01-03	-0.733393	-0.335276
2013-01-04	0.770212	-1.936564

Reduction in the dimensions of the returned object:

In [29]: df.loc["20130102", ["A", "B"]]

Out[29]:

A	-0.942121
B	-0.758401
Name:	2013-01-02 00:00:00, dtype: float64

For getting a scalar value:

```
In [30]: df.loc[dates[0], "A"]
Out[30]: -1.32559115465652
```

For getting fast access to a scalar (equivalent to the prior method):

```
In [31]: df.at[dates[0], "A"]
Out[31]: -1.32559115465652
```

Selection by position

See more in [Selection by Position](#).

Select via the position of the passed integers:

```
In [32]: df.iloc[3]
Out[32]:
A    0.770212
B   -1.936564
C   -0.065106
D   -1.720420
Name: 2013-01-04 00:00:00, dtype: float64
```

By integer slices, acting similar to NumPy/Python:

```
In [33]: df.iloc[3:5, 0:2]
Out[33]:
          A      B
2013-01-04  0.770212 -1.936564
2013-01-05 -0.128739  0.040554
```

By lists of integer position locations, similar to the NumPy/Python style:

```
In [34]: df.iloc[[1, 2, 4], [0, 2]]
Out[34]:
          A      C
2013-01-02 -0.942121 -0.052704
2013-01-03 -0.733393 -2.004442
2013-01-05 -0.128739  0.514148
```

For slicing rows explicitly:

```
In [35]: df.iloc[1:3, :]
Out[35]:
          A      B      C      D
2013-01-02 -0.942121 -0.758401 -0.052704  0.282167
2013-01-03 -0.733393 -0.335276 -2.004442  0.363065
```

For slicing columns explicitly:

```
In [36]: df.iloc[:, 1:3]
Out[36]:
          B      C
```

(continues on next page)

(continued from previous page)

2013-01-01	-0.336537	0.401489
2013-01-02	-0.758401	-0.052704
2013-01-03	-0.335276	-2.004442
2013-01-04	-1.936564	-0.065106
2013-01-05	0.040554	0.514148
2013-01-06	0.557386	-0.476266

For getting a value explicitly:

In [37]:	df.iloc[1, 1]
Out[37]:	-0.7584007081724556

For getting fast access to a scalar (equivalent to the prior method):

In [38]:	df.iat[1, 1]
Out[38]:	-0.7584007081724556

Boolean indexing

Using a single column's values to select data:

In [39]:	df[df["A"] > 0]
Out[39]:	A B C D 2013-01-04 0.770212 -1.936564 -0.065106 -1.72042

Selecting values from a DataFrame where a boolean condition is met:

In [40]:	df[df > 0]
Out[40]:	A B C D 2013-01-01 NaN NaN 0.401489 0.752909 2013-01-02 NaN NaN NaN 0.282167 2013-01-03 NaN NaN NaN 0.363065 2013-01-04 0.770212 NaN NaN NaN 2013-01-05 NaN 0.040554 0.514148 1.588288 2013-01-06 NaN 0.557386 NaN 1.107157

Using the `isin()` method for filtering:

In [41]:	df2 = df.copy()
In [42]:	df2["E"] = ["one", "one", "two", "three", "four", "three"]
In [43]:	df2
Out[43]:	A B C D E 2013-01-01 -1.325591 -0.336537 0.401489 0.752909 one 2013-01-02 -0.942121 -0.758401 -0.052704 0.282167 one 2013-01-03 -0.733393 -0.335276 -2.004442 0.363065 two 2013-01-04 0.770212 -1.936564 -0.065106 -1.720420 three 2013-01-05 -0.128739 0.040554 0.514148 1.588288 four

(continues on next page)

(continued from previous page)

```
2013-01-06 -0.486114  0.557386 -0.476266  1.107157  three
```

In [44]: df2[df2["E"].isin(["two", "four"])]

Out[44]:

	A	B	C	D	E
2013-01-03	-0.733393	-0.335276	-2.004442	0.363065	two
2013-01-05	-0.128739	0.040554	0.514148	1.588288	four

Setting

Setting a new column automatically aligns the data by the indexes:

In [45]: s1 = pd.Series([1, 2, 3, 4, 5, 6], index=pd.date_range("20130102", periods=6))

In [46]: s1

Out[46]:

2013-01-02	1
2013-01-03	2
2013-01-04	3
2013-01-05	4
2013-01-06	5
2013-01-07	6

Freq: D, dtype: int64

In [47]: df["F"] = s1

Setting values by label:

In [48]: df.at[dates[0], "A"] = 0

Setting values by position:

In [49]: df.iat[0, 1] = 0

Setting by assigning with a NumPy array:

In [50]: df.loc[:, "D"] = np.array([5] * len(df))

The result of the prior setting operations:

In [51]: df

Out[51]:

	A	B	C	D	F
2013-01-01	0.000000	0.000000	0.401489	5	NaN
2013-01-02	-0.942121	-0.758401	-0.052704	5	1.0
2013-01-03	-0.733393	-0.335276	-2.004442	5	2.0
2013-01-04	0.770212	-1.936564	-0.065106	5	3.0
2013-01-05	-0.128739	0.040554	0.514148	5	4.0
2013-01-06	-0.486114	0.557386	-0.476266	5	5.0

A where operation with setting:

```
In [52]: df2 = df.copy()
```

```
In [53]: df2[df2 > 0] = -df2
```

```
In [54]: df2
```

```
Out[54]:
```

```
A          B          C  D      F  
2013-01-01  0.000000  0.000000 -0.401489 -5  NaN  
2013-01-02 -0.942121 -0.758401 -0.052704 -5 -1.0  
2013-01-03 -0.733393 -0.335276 -2.004442 -5 -2.0  
2013-01-04 -0.770212 -1.936564 -0.065106 -5 -3.0  
2013-01-05 -0.128739 -0.040554 -0.514148 -5 -4.0  
2013-01-06 -0.486114 -0.557386 -0.476266 -5 -5.0
```

2.1.4 Missing data

pandas primarily uses the value `np.nan` to represent missing data. It is by default not included in computations. See the [Missing Data section](#).

Reindexing allows you to change/add/delete the index on a specified axis. This returns a copy of the data:

```
In [55]: df1 = df.reindex(index=dates[0:4], columns=list(df.columns) + ["E"])
```

```
In [56]: df1.loc[dates[0] : dates[1], "E"] = 1
```

```
In [57]: df1
```

```
Out[57]:
```

```
A          B          C  D      F      E  
2013-01-01  0.000000  0.000000  0.401489  5  NaN  1.0  
2013-01-02 -0.942121 -0.758401 -0.052704  5  1.0  1.0  
2013-01-03 -0.733393 -0.335276 -2.004442  5  2.0  NaN  
2013-01-04 -0.770212 -1.936564 -0.065106  5  3.0  NaN
```

To drop any rows that have missing data:

```
In [58]: df1.dropna(how="any")
```

```
Out[58]:
```

```
A          B          C  D      F      E  
2013-01-02 -0.942121 -0.758401 -0.052704  5  1.0  1.0
```

Filling missing data:

```
In [59]: df1.fillna(value=5)
```

```
Out[59]:
```

```
A          B          C  D      F      E  
2013-01-01  0.000000  0.000000  0.401489  5  5.0  1.0  
2013-01-02 -0.942121 -0.758401 -0.052704  5  1.0  1.0  
2013-01-03 -0.733393 -0.335276 -2.004442  5  2.0  5.0  
2013-01-04 -0.770212 -1.936564 -0.065106  5  3.0  5.0
```

To get the boolean mask where values are `nan`:

```
In [60]: pd.isna(df1)
Out[60]:
      A      B      C      D      F      E
2013-01-01  False  False  False  False   True  False
2013-01-02  False  False  False  False  False  False
2013-01-03  False  False  False  False  False   True
2013-01-04  False  False  False  False  False  True
```

2.1.5 Operations

See the [Basic section on Binary Ops.](#)

Stats

Operations in general *exclude* missing data.

Performing a descriptive statistic:

```
In [61]: df.mean()
Out[61]:
A    -0.253359
B    -0.405383
C    -0.280480
D     5.000000
F     3.000000
dtype: float64
```

Same operation on the other axis:

```
In [62]: df.mean(1)
Out[62]:
2013-01-01    1.350372
2013-01-02    0.849355
2013-01-03    0.785378
2013-01-04    1.353708
2013-01-05    1.885193
2013-01-06    1.919001
Freq: D, dtype: float64
```

Operating with objects that have different dimensionality and need alignment. In addition, pandas automatically broadcasts along the specified dimension:

```
In [63]: s = pd.Series([1, 3, 5, np.nan, 6, 8], index=dates).shift(2)

In [64]: s
Out[64]:
2013-01-01    NaN
2013-01-02    NaN
2013-01-03    1.0
2013-01-04    3.0
2013-01-05    5.0
2013-01-06    NaN
```

(continues on next page)

(continued from previous page)

```
Freq: D, dtype: float64
```

```
In [65]: df.sub(s, axis="index")
```

```
Out[65]:
```

	A	B	C	D	F
2013-01-01	NaN	NaN	NaN	NaN	NaN
2013-01-02	NaN	NaN	NaN	NaN	NaN
2013-01-03	-1.733393	-1.335276	-3.004442	4.0	1.0
2013-01-04	-2.229788	-4.936564	-3.065106	2.0	0.0
2013-01-05	-5.128739	-4.959446	-4.485852	0.0	-1.0
2013-01-06	NaN	NaN	NaN	NaN	NaN

Apply

Applying functions to the data:

```
In [66]: df.apply(np.cumsum)
```

```
Out[66]:
```

	A	B	C	D	F
2013-01-01	0.000000	0.000000	0.401489	5	NaN
2013-01-02	-0.942121	-0.758401	0.348785	10	1.0
2013-01-03	-1.675515	-1.093676	-1.655657	15	3.0
2013-01-04	-0.905303	-3.030240	-1.720764	20	6.0
2013-01-05	-1.034042	-2.989686	-1.206615	25	10.0
2013-01-06	-1.520157	-2.432300	-1.682882	30	15.0

```
In [67]: df.apply(lambda x: x.max() - x.min())
```

```
Out[67]:
```

A	1.712333
B	2.493950
C	2.518590
D	0.000000
F	4.000000
dtype: float64	

Histogramming

See more at [Histogramming and Discretization](#).

```
In [68]: s = pd.Series(np.random.randint(0, 7, size=10))
```

```
In [69]: s
```

```
Out[69]:
```

0	2
1	5
2	1
3	1
4	2
5	5
6	4

(continues on next page)

(continued from previous page)

```

7    3
8    1
9    6
dtype: int64

In [70]: s.value_counts()
Out[70]:
1    3
2    2
5    2
4    1
3    1
6    1
dtype: int64

```

String Methods

Series is equipped with a set of string processing methods in the `str` attribute that make it easy to operate on each element of the array, as in the code snippet below. Note that pattern-matching in `str` generally uses regular expressions by default (and in some cases always uses them). See more at [Vectorized String Methods](#).

```

In [71]: s = pd.Series(["A", "B", "C", "Aaba", "Baca", np.nan, "CABA", "dog", "cat"])

In [72]: s.str.lower()
Out[72]:
0      a
1      b
2      c
3     aaba
4     baca
5      NaN
6     cab
7     dog
8     cat
dtype: object

```

2.1.6 Merge

Concat

pandas provides various facilities for easily combining together Series and DataFrame objects with various kinds of set logic for the indexes and relational algebra functionality in the case of join / merge-type operations.

See the [Merging section](#).

Concatenating pandas objects together with `concat()`:

```

In [73]: df = pd.DataFrame(np.random.randn(10, 4))

In [74]: df
Out[74]:

```

(continues on next page)

(continued from previous page)

	0	1	2	3
0	-1.156642	0.448783	-0.103055	0.595429
1	-0.510558	-0.310790	-0.885025	-0.543387
2	-0.088470	-0.205108	-0.216988	1.400121
3	0.965002	0.605406	0.580077	-0.334156
4	1.170972	-0.360568	0.153389	-0.756219
5	0.558189	-0.280232	1.240799	2.428736
6	0.912933	-0.368246	0.463732	-0.495179
7	0.950022	0.228997	1.900632	0.936138
8	-0.132966	-0.405778	0.252775	-1.280320
9	0.912028	-0.367162	0.687391	-0.067812

break it into pieces

In [75]: pieces = [df[:3], df[3:7], df[7:]]**In [76]:** pd.concat(pieces)**Out[76]:**

	0	1	2	3
0	-1.156642	0.448783	-0.103055	0.595429
1	-0.510558	-0.310790	-0.885025	-0.543387
2	-0.088470	-0.205108	-0.216988	1.400121
3	0.965002	0.605406	0.580077	-0.334156
4	1.170972	-0.360568	0.153389	-0.756219
5	0.558189	-0.280232	1.240799	2.428736
6	0.912933	-0.368246	0.463732	-0.495179
7	0.950022	0.228997	1.900632	0.936138
8	-0.132966	-0.405778	0.252775	-1.280320
9	0.912028	-0.367162	0.687391	-0.067812

Note: Adding a column to a DataFrame is relatively fast. However, adding a row requires a copy, and may be expensive. We recommend passing a pre-built list of records to the DataFrame constructor instead of building a DataFrame by iteratively appending records to it.

Join

SQL style merges. See the *Database style joining* section.**In [77]:** left = pd.DataFrame({"key": ["foo", "foo"], "lval": [1, 2]})**In [78]:** right = pd.DataFrame({"key": ["foo", "foo"], "rval": [4, 5]})**In [79]:** left**Out[79]:**

key	lval	
0	foo	1
1	foo	2

In [80]: right**Out[80]:**

(continues on next page)

(continued from previous page)

```

key    rval
0  foo      4
1  foo      5

In [81]: pd.merge(left, right, on="key")
Out[81]:
key    lval    rval
0  foo      1      4
1  foo      1      5
2  foo      2      4
3  foo      2      5

```

Another example that can be given is:

```

In [82]: left = pd.DataFrame({"key": ["foo", "bar"], "lval": [1, 2]})

In [83]: right = pd.DataFrame({"key": ["foo", "bar"], "rval": [4, 5]})

In [84]: left
Out[84]:
key    lval
0  foo      1
1  bar      2

In [85]: right
Out[85]:
key    rval
0  foo      4
1  bar      5

In [86]: pd.merge(left, right, on="key")
Out[86]:
key    lval    rval
0  foo      1      4
1  bar      2      5

```

2.1.7 Grouping

By “group by” we are referring to a process involving one or more of the following steps:

- **Splitting** the data into groups based on some criteria
- **Applying** a function to each group independently
- **Combining** the results into a data structure

See the [Grouping section](#).

```

In [87]: df = pd.DataFrame(
.....    {
.....        "A": ["foo", "bar", "foo", "bar", "foo", "bar", "foo", "foo"],
.....        "B": ["one", "one", "two", "three", "two", "two", "one", "three"],
.....        "C": np.random.randn(8),

```

(continues on next page)

(continued from previous page)

```
....:  
        "D": np.random.randn(8),  
....:  
    }  
....:  
}  
....:
```

In [88]: df

Out[88]:

	A	B	C	D
0	foo	one	-0.656076	2.100764
1	bar	one	-0.420989	-0.552912
2	foo	two	0.186369	0.015360
3	bar	three	1.807672	0.024979
4	foo	two	0.075781	0.262508
5	bar	two	0.756661	-1.347097
6	foo	one	-1.010777	-0.168360
7	foo	three	-1.709692	0.731181

Grouping and then applying the `sum()` function to the resulting groups:

In [89]: df.groupby("A").sum()

Out[89]:

	C	D
A		
bar	2.143344	-1.875030
foo	-3.114396	2.941453

Grouping by multiple columns forms a hierarchical index, and again we can apply the `sum()` function:

In [90]: df.groupby(["A", "B"]).sum()

Out[90]:

	A	B	C	D
bar	one	-0.420989	-0.552912	
	three	1.807672	0.024979	
	two	0.756661	-1.347097	
foo	one	-1.666853	1.932404	
	three	-1.709692	0.731181	
	two	0.262149	0.277868	

2.1.8 Reshaping

See the sections on [Hierarchical Indexing](#) and [Reshaping](#).

Stack

```
In [91]: tuples = list(
...:     zip(
...:         *[[
...:             ["bar", "bar", "baz", "baz", "foo", "foo", "qux", "qux"],
...:             ["one", "two", "one", "two", "one", "two", "one", "two"],
...:         ]])
...:     )
...: )

In [92]: index = pd.MultiIndex.from_tuples(tuples, names=["first", "second"])

In [93]: df = pd.DataFrame(np.random.randn(8, 2), index=index, columns=["A", "B"])

In [94]: df2 = df[:4]

In [95]: df2
Out[95]:
          A        B
first second
bar   one    1.622853 -0.232267
      two    0.686548 -1.534020
baz   one    0.925424  1.387692
      two   -1.247546  1.146858
```

The `stack()` method “compresses” a level in the DataFrame’s columns:

```
In [96]: stacked = df2.stack()

In [97]: stacked
Out[97]:
          first  second
bar   one      A    1.622853
                  B   -0.232267
              two      A    0.686548
                  B   -1.534020
baz   one      A    0.925424
                  B    1.387692
              two      A   -1.247546
                  B    1.146858
dtype: float64
```

With a “stacked” DataFrame or Series (having a MultiIndex as the index), the inverse operation of `stack()` is `unstack()`, which by default unstacks the **last level**:

```
In [98]: stacked.unstack()
Out[98]:
```

(continues on next page)

(continued from previous page)

```
A      B
first second
bar   one    1.622853 -0.232267
      two     0.686548 -1.534020
baz   one    0.925424  1.387692
      two    -1.247546  1.146858
```

In [99]: stacked.unstack(1)**Out[99]:**

```
second      one      two
first
bar   A  1.622853  0.686548
      B -0.232267 -1.534020
baz   A  0.925424 -1.247546
      B  1.387692  1.146858
```

In [100]: stacked.unstack(0)**Out[100]:**

```
first      bar      baz
second
one   A  1.622853  0.925424
      B -0.232267  1.387692
two   A  0.686548 -1.247546
      B -1.534020  1.146858
```

Pivot tables

See the section on [Pivot Tables](#).

```
In [101]: df = pd.DataFrame(
...:     {
...:         "A": ["one", "one", "two", "three"] * 3,
...:         "B": ["A", "B", "C"] * 4,
...:         "C": ["foo", "foo", "foo", "bar", "bar", "bar"] * 2,
...:         "D": np.random.randn(12),
...:         "E": np.random.randn(12),
...:     }
...: )
...:
```

In [102]: df

```
Out[102]:
       A  B      C      D      E
0    one  A  foo  0.571303 -0.283694
1    one  B  foo  0.597649 -0.344110
2    two  C  foo -0.348892  0.993136
3  three  A  bar -1.088158 -0.649614
4    one  B  bar  2.032043 -0.625472
5    one  C  bar -0.983588 -1.754765
6    two  A  foo  0.796674 -0.954840
7  three  B  foo -0.663216  1.149934
```

(continues on next page)

(continued from previous page)

```
8      one  C  foo -1.258631 -0.027185
9      one  A  bar -0.216001  0.963286
10     two  B  bar  0.078620  0.584818
11    three  C  bar  0.869189  1.591697
```

We can produce pivot tables from this data very easily:

```
In [103]: pd.pivot_table(df, values="D", index=["A", "B"], columns=["C"])
```

```
Out[103]:
```

		bar	foo
A	B		
one	A	-0.216001	0.571303
	B	2.032043	0.597649
	C	-0.983588	-1.258631
three	A	-1.088158	NaN
	B	NaN	-0.663216
	C	0.869189	NaN
two	A	NaN	0.796674
	B	0.078620	NaN
	C	NaN	-0.348892

2.1.9 Time series

pandas has simple, powerful, and efficient functionality for performing resampling operations during frequency conversion (e.g., converting secondly data into 5-minute data). This is extremely common in, but not limited to, financial applications. See the [Time Series section](#).

```
In [104]: rng = pd.date_range("1/1/2012", periods=100, freq="S")
```

```
In [105]: ts = pd.Series(np.random.randint(0, 500, len(rng)), index=rng)
```

```
In [106]: ts.resample("5Min").sum()
```

```
Out[106]:
```

2012-01-01	20462
Freq:	5T, dtype: int64

Time zone representation:

```
In [107]: rng = pd.date_range("3/6/2012 00:00", periods=5, freq="D")
```

```
In [108]: ts = pd.Series(np.random.randn(len(rng)), rng)
```

```
In [109]: ts
```

```
Out[109]:
```

2012-03-06	-1.674564
2012-03-07	0.750881
2012-03-08	0.475429
2012-03-09	0.671150
2012-03-10	-2.616932
Freq:	D, dtype: float64

(continues on next page)

(continued from previous page)

```
In [110]: ts_utc = ts.tz_localize("UTC")
```

```
In [111]: ts_utc
```

```
Out[111]:
```

```
2012-03-06 00:00:00+00:00    -1.674564  
2012-03-07 00:00:00+00:00     0.750881  
2012-03-08 00:00:00+00:00     0.475429  
2012-03-09 00:00:00+00:00     0.671150  
2012-03-10 00:00:00+00:00    -2.616932  
Freq: D, dtype: float64
```

Converting to another time zone:

```
In [112]: ts_utc.tz_convert("US/Eastern")
```

```
Out[112]:
```

```
2012-03-05 19:00:00-05:00    -1.674564  
2012-03-06 19:00:00-05:00     0.750881  
2012-03-07 19:00:00-05:00     0.475429  
2012-03-08 19:00:00-05:00     0.671150  
2012-03-09 19:00:00-05:00    -2.616932  
Freq: D, dtype: float64
```

Converting between time span representations:

```
In [113]: rng = pd.date_range("1/1/2012", periods=5, freq="M")
```

```
In [114]: ts = pd.Series(np.random.randn(len(rng)), index=rng)
```

```
In [115]: ts
```

```
Out[115]:
```

```
2012-01-31    -0.246723  
2012-02-29     0.714166  
2012-03-31     1.903492  
2012-04-30    -0.890850  
2012-05-31    -1.220504  
Freq: M, dtype: float64
```

```
In [116]: ps = ts.to_period()
```

```
In [117]: ps
```

```
Out[117]:
```

```
2012-01    -0.246723  
2012-02     0.714166  
2012-03     1.903492  
2012-04    -0.890850  
2012-05    -1.220504  
Freq: M, dtype: float64
```

```
In [118]: ps.to_timestamp()
```

```
Out[118]:
```

```
2012-01-01    -0.246723  
2012-02-01     0.714166
```

(continues on next page)

(continued from previous page)

```
2012-03-01    1.903492
2012-04-01   -0.890850
2012-05-01   -1.220504
Freq: MS, dtype: float64
```

Converting between period and timestamp enables some convenient arithmetic functions to be used. In the following example, we convert a quarterly frequency with year ending in November to 9am of the end of the month following the quarter end:

```
In [119]: prng = pd.period_range("1990Q1", "2000Q4", freq="Q-NOV")
In [120]: ts = pd.Series(np.random.randn(len(prng)), prng)
In [121]: ts.index = (prng.asfreq("M", "e") + 1).asfreq("H", "s") + 9
In [122]: ts.head()
Out[122]:
1990-03-01 09:00    1.374209
1990-06-01 09:00    0.701162
1990-09-01 09:00    0.734917
1990-12-01 09:00   -1.715392
1991-03-01 09:00   -0.216692
Freq: H, dtype: float64
```

2.1.10 Categoricals

pandas can include categorical data in a `DataFrame`. For full docs, see the [categorical introduction](#) and the [API documentation](#).

```
In [123]: df = pd.DataFrame(
.....:     {"id": [1, 2, 3, 4, 5, 6], "raw_grade": ["a", "b", "b", "a", "a", "e"]}
.....: )
.....:
```

Converting the raw grades to a categorical data type:

```
In [124]: df["grade"] = df["raw_grade"].astype("category")
In [125]: df["grade"]
Out[125]:
0    a
1    b
2    b
3    a
4    a
5    e
Name: grade, dtype: category
Categories (3, object): ['a', 'b', 'e']
```

Rename the categories to more meaningful names (assigning to `Series.cat.categories()` is in place!):

```
In [126]: df["grade"].cat.categories = ["very good", "good", "very bad"]
```

Reorder the categories and simultaneously add the missing categories (methods under Series.cat() return a new Series by default):

```
In [127]: df["grade"] = df["grade"].cat.set_categories(  
.....:     ["very bad", "bad", "medium", "good", "very good"]  
.....: )  
.....:
```

```
In [128]: df["grade"]
```

```
Out[128]:
```

```
0    very good  
1        good  
2        good  
3    very good  
4    very good  
5      very bad  
Name: grade, dtype: category  
Categories (5, object): ['very bad', 'bad', 'medium', 'good', 'very good']
```

Sorting is per order in the categories, not lexical order:

```
In [129]: df.sort_values(by="grade")
```

```
Out[129]:
```

```
   id raw_grade      grade  
5   6          e  very bad  
1   2          b      good  
2   3          b      good  
0   1          a  very good  
3   4          a  very good  
4   5          a  very good
```

Grouping by a categorical column also shows empty categories:

```
In [130]: df.groupby("grade").size()
```

```
Out[130]:
```

```
grade  
very bad      1  
bad           0  
medium         0  
good           2  
very good     3  
dtype: int64
```

2.1.11 Plotting

See the [Plotting](#) docs.

We use the standard convention for referencing the matplotlib API:

```
In [131]: import matplotlib.pyplot as plt
```

```
In [132]: plt.close("all")
```

The `close()` method is used to `close` a figure window:

```
In [133]: ts = pd.Series(np.random.randn(1000), index=pd.date_range("1/1/2000", periods=1000))
```

```
In [134]: ts = ts.cumsum()
```

```
In [135]: ts.plot();
```

If running under Jupyter Notebook, the plot will appear on `plot()`. Otherwise use `matplotlib.pyplot.show` to show it or `matplotlib.pyplot.savefig` to write it to a file.

```
In [136]: plt.show();
```

On a DataFrame, the `plot()` method is a convenience to plot all of the columns with labels:

```
In [137]: df = pd.DataFrame(  
.....:     np.random.randn(1000, 4), index=ts.index, columns=["A", "B", "C", "D"]  
.....:  
.....:  
In [138]: df = df.cumsum()  
  
In [139]: plt.figure();  
  
In [140]: df.plot();  
  
In [141]: plt.legend(loc='best');
```

2.1.12 Getting data in/out

CSV

Writing to a csv file:

```
In [142]: df.to_csv("foo.csv")
```

Reading from a csv file:

```
In [143]: pd.read_csv("foo.csv")
```

Out[143]:

	Unnamed: 0	A	B	C	D
0	2000-01-01	-0.044747	-0.830584	0.518126	0.117110
1	2000-01-02	-0.931010	-0.188137	0.590739	-0.065270

[1000 rows x 5 columns]

HDF5

Reading and writing to *HDFStores*.

Writing to a HDF5 Store:

```
In [144]: df.to_hdf("foo.h5", "df")
```

Reading from a HDF5 Store:

```
In [145]: pd.read_hdf("foo.h5", "df")
```

Out[145]:

	A	B	C	D
2000-01-01	-0.044747	-0.830584	0.518126	0.117110

[1000 rows x 5 columns]

2.1.13 Gotchas

If you are attempting to perform an operation you might see an exception like:

```
>>> if pd.Series([False, True, False]):  
...     print("I was true")  
Traceback  
...  
ValueError: The truth value of an array is ambiguous. Use a.empty, a.any() or a.all().
```

See *Comparisons* for an explanation and what to do.

See *Gotchas* as well.

2.2 Intro to data structures

We'll start with a quick, non-comprehensive overview of the fundamental data structures in pandas to get you started. The fundamental behavior about data types, indexing, and axis labeling / alignment apply across all of the objects. To get started, import NumPy and load pandas into your namespace:

```
In [1]: import numpy as np
```

```
In [2]: import pandas as pd
```

Here is a basic tenet to keep in mind: **data alignment is intrinsic**. The link between labels and data will not be broken unless done so explicitly by you.

We'll give a brief intro to the data structures, then consider all of the broad categories of functionality and methods in separate sections.

2.2.1 Series

`Series` is a one-dimensional labeled array capable of holding any data type (integers, strings, floating point numbers, Python objects, etc.). The axis labels are collectively referred to as the `index`. The basic method to create a Series is to call:

```
>>> s = pd.Series(data, index=index)
```

Here, `data` can be many different things:

- a Python dict
- an ndarray
- a scalar value (like 5)

The passed `index` is a list of axis labels. Thus, this separates into a few cases depending on what `data` is:

From ndarray

If `data` is an ndarray, `index` must be the same length as `data`. If no `index` is passed, one will be created having values `[0, ..., len(data) - 1]`.

```
In [3]: s = pd.Series(np.random.randn(5), index=["a", "b", "c", "d", "e"])
```

```
In [4]: s
```

```
Out[4]:
a    0.469112
b   -0.282863
c   -1.509059
d   -1.135632
e    1.212112
dtype: float64
```

```
In [5]: s.index
```

```
Out[5]: Index(['a', 'b', 'c', 'd', 'e'], dtype='object')
```

```
In [6]: pd.Series(np.random.randn(5))
```

```
Out[6]:
0   -0.173215
1    0.119209
2   -1.044236
3   -0.861849
4   -2.104569
dtype: float64
```

Note: pandas supports non-unique index values. If an operation that does not support duplicate index values is attempted, an exception will be raised at that time. The reason for being lazy is nearly all performance-based (there are many instances in computations, like parts of GroupBy, where the index is not used).

From dict

Series can be instantiated from dicts:

```
In [7]: d = {"b": 1, "a": 0, "c": 2}
```

```
In [8]: pd.Series(d)
```

```
Out[8]:
```

```
b    1  
a    0  
c    2  
dtype: int64
```

Note: When the data is a dict, and an index is not passed, the `Series` index will be ordered by the dict's insertion order, if you're using Python version ≥ 3.6 and pandas version ≥ 0.23 .

If you're using Python < 3.6 or pandas < 0.23 , and an index is not passed, the `Series` index will be the lexically ordered list of dict keys.

In the example above, if you were on a Python version lower than 3.6 or a pandas version lower than 0.23, the `Series` would be ordered by the lexical order of the dict keys (i.e. `['a', 'b', 'c']` rather than `['b', 'a', 'c']`).

If an index is passed, the values in data corresponding to the labels in the index will be pulled out.

```
In [9]: d = {"a": 0.0, "b": 1.0, "c": 2.0}
```

```
In [10]: pd.Series(d)
```

```
Out[10]:
```

```
a    0.0  
b    1.0  
c    2.0  
dtype: float64
```

```
In [11]: pd.Series(d, index=["b", "c", "d", "a"])
```

```
Out[11]:
```

```
b    1.0  
c    2.0  
d    NaN  
a    0.0  
dtype: float64
```

Note: `NaN` (not a number) is the standard missing data marker used in pandas.

From scalar value

If data is a scalar value, an index must be provided. The value will be repeated to match the length of `index`.

```
In [12]: pd.Series(5.0, index=["a", "b", "c", "d", "e"])
```

```
Out[12]:
```

```
a    5.0  
b    5.0  
c    5.0  
d    5.0  
e    5.0  
dtype: float64
```

Series is ndarray-like

`Series` acts very similarly to a `ndarray`, and is a valid argument to most NumPy functions. However, operations such as slicing will also slice the index.

```
In [13]: s[0]
Out[13]: 0.4691122999071863
```

```
In [14]: s[:3]
Out[14]:
```

```
a    0.469112
b   -0.282863
c   -1.509059
dtype: float64
```

```
In [15]: s[s > s.median()]
Out[15]:
```

```
a    0.469112
e   1.212112
dtype: float64
```

```
In [16]: s[[4, 3, 1]]
Out[16]:
```

```
e   1.212112
d   -1.135632
b   -0.282863
dtype: float64
```

```
In [17]: np.exp(s)
Out[17]:
```

```
a    1.598575
b    0.753623
c    0.221118
d    0.321219
e    3.360575
dtype: float64
```

Note: We will address array-based indexing like `s[[4, 3, 1]]` in [section on indexing](#).

Like a NumPy array, a pandas Series has a `dtype`.

```
In [18]: s.dtype
Out[18]: dtype('float64')
```

This is often a NumPy `dtype`. However, pandas and 3rd-party libraries extend NumPy's type system in a few places, in which case the `dtype` would be an [Extension Dtype](#). Some examples within pandas are [Categorical data](#) and [Nullable integer data type](#). See [dtypes](#) for more.

If you need the actual array backing a `Series`, use `Series.array`.

```
In [19]: s.array
Out[19]:
<PandasArray>
```

(continues on next page)

(continued from previous page)

```
[ 0.4691122999071863, -0.2828633443286633, -1.5090585031735124,
 -1.1356323710171934,  1.2121120250208506]
Length: 5, dtype: float64
```

Accessing the array can be useful when you need to do some operation without the index (to disable *automatic alignment*, for example).

`Series.array` will always be an `ExtensionArray`. Briefly, an ExtensionArray is a thin wrapper around one or more *concrete* arrays like a `numpy.ndarray`. pandas knows how to take an ExtensionArray and store it in a Series or a column of a DataFrame. See `dtypes` for more.

While Series is ndarray-like, if you need an *actual* ndarray, then use `Series.to_numpy()`.

```
In [20]: s.to_numpy()
Out[20]: array([ 0.4691, -0.2829, -1.5091, -1.1356,  1.2121])
```

Even if the Series is backed by a `ExtensionArray`, `Series.to_numpy()` will return a NumPy ndarray.

Series is dict-like

A Series is like a fixed-size dict in that you can get and set values by index label:

```
In [21]: s["a"]
Out[21]: 0.4691122999071863

In [22]: s["e"] = 12.0

In [23]: s
Out[23]:
a    0.469112
b   -0.282863
c   -1.509059
d   -1.135632
e    12.000000
dtype: float64

In [24]: "e" in s
Out[24]: True

In [25]: "f" in s
Out[25]: False
```

If a label is not contained, an exception is raised:

```
>>> s["f"]
KeyError: 'f'
```

Using the `get` method, a missing label will return None or specified default:

```
In [26]: s.get("f")
In [27]: s.get("f", np.nan)
Out[27]: nan
```

See also the [section on attribute access](#).

Vectorized operations and label alignment with Series

When working with raw NumPy arrays, looping through value-by-value is usually not necessary. The same is true when working with Series in pandas. Series can also be passed into most NumPy methods expecting an ndarray.

```
In [28]: s + s
```

```
Out[28]:
```

```
a      0.938225
b     -0.565727
c    -3.018117
d    -2.271265
e    24.000000
dtype: float64
```

```
In [29]: s * 2
```

```
Out[29]:
```

```
a      0.938225
b     -0.565727
c    -3.018117
d    -2.271265
e    24.000000
dtype: float64
```

```
In [30]: np.exp(s)
```

```
Out[30]:
```

```
a      1.598575
b      0.753623
c      0.221118
d      0.321219
e    162754.791419
dtype: float64
```

A key difference between Series and ndarray is that operations between Series automatically align the data based on label. Thus, you can write computations without giving consideration to whether the Series involved have the same labels.

```
In [31]: s[1:] + s[:-1]
```

```
Out[31]:
```

```
a        NaN
b     -0.565727
c    -3.018117
d    -2.271265
e        NaN
dtype: float64
```

The result of an operation between unaligned Series will have the **union** of the indexes involved. If a label is not found in one Series or the other, the result will be marked as missing NaN. Being able to write code without doing any explicit data alignment grants immense freedom and flexibility in interactive data analysis and research. The integrated data alignment features of the pandas data structures set pandas apart from the majority of related tools for working with labeled data.

Note: In general, we chose to make the default result of operations between differently indexed objects yield the **union** of the indexes in order to avoid loss of information. Having an index label, though the data is missing, is typically important information as part of a computation. You of course have the option of dropping labels with missing data via the **dropna** function.

Name attribute

Series can also have a name attribute:

```
In [32]: s = pd.Series(np.random.randn(5), name="something")
```

```
In [33]: s
```

```
Out[33]:
```

```
0    -0.494929  
1     1.071804  
2     0.721555  
3    -0.706771  
4    -1.039575  
Name: something, dtype: float64
```

```
In [34]: s.name
```

```
Out[34]: 'something'
```

The Series name will be assigned automatically in many cases, in particular when taking 1D slices of DataFrame as you will see below.

You can rename a Series with the `pandas.Series.rename()` method.

```
In [35]: s2 = s.rename("different")
```

```
In [36]: s2.name
```

```
Out[36]: 'different'
```

Note that `s` and `s2` refer to different objects.

2.2.2 DataFrame

DataFrame is a 2-dimensional labeled data structure with columns of potentially different types. You can think of it like a spreadsheet or SQL table, or a dict of Series objects. It is generally the most commonly used pandas object. Like Series, DataFrame accepts many different kinds of input:

- Dict of 1D ndarrays, lists, dicts, or Series
- 2-D numpy.ndarray
- Structured or record ndarray
- A Series
- Another DataFrame

Along with the data, you can optionally pass **index** (row labels) and **columns** (column labels) arguments. If you pass an index and / or columns, you are guaranteeing the index and / or columns of the resulting DataFrame. Thus, a dict of Series plus a specific index will discard all data not matching up to the passed index.

If axis labels are not passed, they will be constructed from the input data based on common sense rules.

Note: When the data is a dict, and `columns` is not specified, the `DataFrame` columns will be ordered by the dict's insertion order, if you are using Python version ≥ 3.6 and pandas ≥ 0.23 .

If you are using Python < 3.6 or pandas < 0.23 , and `columns` is not specified, the `DataFrame` columns will be the lexically ordered list of dict keys.

From dict of Series or dicts

The resulting `index` will be the **union** of the indexes of the various Series. If there are any nested dicts, these will first be converted to Series. If no columns are passed, the columns will be the ordered list of dict keys.

```
In [37]: d = {
    ....:     "one": pd.Series([1.0, 2.0, 3.0], index=["a", "b", "c"]),
    ....:     "two": pd.Series([1.0, 2.0, 3.0, 4.0], index=["a", "b", "c", "d"]),
    ....: }
    ....:

In [38]: df = pd.DataFrame(d)

In [39]: df
Out[39]:
   one  two
a  1.0  1.0
b  2.0  2.0
c  3.0  3.0
d  NaN  4.0

In [40]: pd.DataFrame(d, index=["d", "b", "a"])
Out[40]:
   one  two
d  NaN  4.0
b  2.0  2.0
a  1.0  1.0

In [41]: pd.DataFrame(d, index=["d", "b", "a"], columns=["two", "three"])
Out[41]:
   two  three
d  4.0    NaN
b  2.0    NaN
a  1.0    NaN
```

The row and column labels can be accessed respectively by accessing the `index` and `columns` attributes:

Note: When a particular set of columns is passed along with a dict of data, the passed columns override the keys in the dict.

```
In [42]: df.index
Out[42]: Index(['a', 'b', 'c', 'd'], dtype='object')
```

(continues on next page)

(continued from previous page)

```
In [43]: df.columns  
Out[43]: Index(['one', 'two'], dtype='object')
```

From dict of ndarrays / lists

The ndarrays must all be the same length. If an index is passed, it must clearly also be the same length as the arrays. If no index is passed, the result will be `range(n)`, where `n` is the array length.

```
In [44]: d = {"one": [1.0, 2.0, 3.0, 4.0], "two": [4.0, 3.0, 2.0, 1.0]}
```

```
In [45]: pd.DataFrame(d)  
Out[45]:  
      one   two  
0    1.0   4.0  
1    2.0   3.0  
2    3.0   2.0  
3    4.0   1.0
```

```
In [46]: pd.DataFrame(d, index=["a", "b", "c", "d"])
```

```
Out[46]:  
      one   two  
a    1.0   4.0  
b    2.0   3.0  
c    3.0   2.0  
d    4.0   1.0
```

From structured or record array

This case is handled identically to a dict of arrays.

```
In [47]: data = np.zeros((2,), dtype=[("A", "i4"), ("B", "f4"), ("C", "a10")])
```

```
In [48]: data[:] = [(1, 2.0, "Hello"), (2, 3.0, "World")]
```

```
In [49]: pd.DataFrame(data)  
Out[49]:  
      A      B      C  
0    1    2.0  b'Hello'  
1    2    3.0  b'World'
```

```
In [50]: pd.DataFrame(data, index=["first", "second"])
```

```
Out[50]:  
      A      B      C  
first  1    2.0  b'Hello'  
second 2    3.0  b'World'
```

```
In [51]: pd.DataFrame(data, columns=["C", "A", "B"])
```

```
Out[51]:  
      C      A      B
```

(continues on next page)

(continued from previous page)

```
0 b'Hello' 1 2.0
1 b'World' 2 3.0
```

Note: DataFrame is not intended to work exactly like a 2-dimensional NumPy ndarray.

From a list of dicts

```
In [52]: data2 = [{"a": 1, "b": 2}, {"a": 5, "b": 10, "c": 20}]
```

```
In [53]: pd.DataFrame(data2)
```

```
Out[53]:
```

	a	b	c
0	1	2	NaN
1	5	10	20.0

```
In [54]: pd.DataFrame(data2, index=["first", "second"])
```

```
Out[54]:
```

	a	b	c
first	1	2	NaN
second	5	10	20.0

```
In [55]: pd.DataFrame(data2, columns=["a", "b"])
```

```
Out[55]:
```

	a	b
0	1	2
1	5	10

From a dict of tuples

You can automatically create a MultiIndexed frame by passing a tuples dictionary.

```
In [56]: pd.DataFrame(
    ....:     {
    ....:         ("a", "b"): {("A", "B"): 1, ("A", "C"): 2},
    ....:         ("a", "a"): {("A", "C"): 3, ("A", "B"): 4},
    ....:         ("a", "c"): {("A", "B"): 5, ("A", "C"): 6},
    ....:         ("b", "a"): {("A", "C"): 7, ("A", "B"): 8},
    ....:         ("b", "b"): {("A", "D"): 9, ("A", "B"): 10},
    ....:     }
    ....:
)
```

```
Out[56]:
```

	a		b		
	b	a	c	a	b
A	1.0	4.0	5.0	8.0	10.0
C	2.0	3.0	6.0	7.0	NaN
D	NaN	NaN	NaN	NaN	9.0

From a Series

The result will be a DataFrame with the same index as the input Series, and with one column whose name is the original name of the Series (only if no other column name provided).

From a list of namedtuples

The field names of the first namedtuple in the list determine the columns of the DataFrame. The remaining namedtuples (or tuples) are simply unpacked and their values are fed into the rows of the DataFrame. If any of those tuples is shorter than the first namedtuple then the later columns in the corresponding row are marked as missing values. If any are longer than the first namedtuple, a ValueError is raised.

```
In [57]: from collections import namedtuple  
  
In [58]: Point = namedtuple("Point", "x y")  
  
In [59]: pd.DataFrame([Point(0, 0), Point(0, 3), (2, 3)])  
Out[59]:  
      x    y  
0    0    0  
1    0    3  
2    2    3  
  
In [60]: Point3D = namedtuple("Point3D", "x y z")  
  
In [61]: pd.DataFrame([Point3D(0, 0, 0), Point3D(0, 3, 5), Point(2, 3)])  
Out[61]:  
      x    y    z  
0    0    0  0.0  
1    0    3  5.0  
2    2    3   NaN
```

From a list of dataclasses

New in version 1.1.0.

Data Classes as introduced in [PEP557](#), can be passed into the DataFrame constructor. Passing a list of dataclasses is equivalent to passing a list of dictionaries.

Please be aware, that all values in the list should be dataclasses, mixing types in the list would result in a TypeError.

```
In [62]: from dataclasses import make_dataclass  
  
In [63]: Point = make_dataclass("Point", [("x", int), ("y", int)])  
  
In [64]: pd.DataFrame([Point(0, 0), Point(0, 3), Point(2, 3)])  
Out[64]:  
      x    y  
0    0    0  
1    0    3  
2    2    3
```

Missing data

Much more will be said on this topic in the [Missing data](#) section. To construct a DataFrame with missing data, we use `np.nan` to represent missing values. Alternatively, you may pass a `numpy.MaskedArray` as the data argument to the DataFrame constructor, and its masked entries will be considered missing.

Alternate constructors

DataFrame.from_dict

`DataFrame.from_dict` takes a dict of dicts or a dict of array-like sequences and returns a DataFrame. It operates like the DataFrame constructor except for the `orient` parameter which is 'columns' by default, but which can be set to 'index' in order to use the dict keys as row labels.

```
In [65]: pd.DataFrame.from_dict(dict([("A", [1, 2, 3]), ("B", [4, 5, 6])]))
Out[65]:
   A   B
0  1  4
1  2  5
2  3  6
```

If you pass `orient='index'`, the keys will be the row labels. In this case, you can also pass the desired column names:

```
In [66]: pd.DataFrame.from_dict(
    ....:     dict([("A", [1, 2, 3]), ("B", [4, 5, 6])]),
    ....:     orient="index",
    ....:     columns=["one", "two", "three"],
    ....: )
....:
Out[66]:
   one   two   three
A    1    2    3
B    4    5    6
```

DataFrame.from_records

`DataFrame.from_records` takes a list of tuples or an ndarray with structured dtype. It works analogously to the normal DataFrame constructor, except that the resulting DataFrame index may be a specific field of the structured dtype. For example:

```
In [67]: data
Out[67]:
array([(1, 2., b'Hello'), (2, 3., b'World')],
      dtype=[('A', '<i4'), ('B', '<f4'), ('C', 'S10')])

In [68]: pd.DataFrame.from_records(data, index="C")
Out[68]:
          A      B
C
b'Hello'  1  2.0
b'World'  2  3.0
```

Column selection, addition, deletion

You can treat a DataFrame semantically like a dict of like-indexed Series objects. Getting, setting, and deleting columns works with the same syntax as the analogous dict operations:

```
In [69]: df["one"]
Out[69]:
a    1.0
b    2.0
c    3.0
d    NaN
Name: one, dtype: float64

In [70]: df["three"] = df["one"] * df["two"]

In [71]: df["flag"] = df["one"] > 2

In [72]: df
Out[72]:
   one  two  three  flag
a  1.0  1.0    1.0  False
b  2.0  2.0    4.0  False
c  3.0  3.0    9.0   True
d  NaN  4.0    NaN  False
```

Columns can be deleted or popped like with a dict:

```
In [73]: del df["two"]

In [74]: three = df.pop("three")

In [75]: df
Out[75]:
   one  flag
a  1.0  False
b  2.0  False
c  3.0   True
d  NaN  False
```

When inserting a scalar value, it will naturally be propagated to fill the column:

```
In [76]: df["foo"] = "bar"

In [77]: df
Out[77]:
   one  flag  foo
a  1.0  False  bar
b  2.0  False  bar
c  3.0   True  bar
d  NaN  False  bar
```

When inserting a Series that does not have the same index as the DataFrame, it will be conformed to the DataFrame's index:

```
In [78]: df["one_trunc"] = df["one"][:2]
```

```
In [79]: df
```

```
Out[79]:
```

	one	flag	foo	one_trunc
a	1.0	False	bar	1.0
b	2.0	False	bar	2.0
c	3.0	True	bar	NaN
d	NaN	False	bar	NaN

You can insert raw ndarrays but their length must match the length of the DataFrame's index.

By default, columns get inserted at the end. The `insert` function is available to insert at a particular location in the columns:

```
In [80]: df.insert(1, "bar", df["one"])
```

```
In [81]: df
```

```
Out[81]:
```

	one	bar	flag	foo	one_trunc
a	1.0	1.0	False	bar	1.0
b	2.0	2.0	False	bar	2.0
c	3.0	3.0	True	bar	NaN
d	NaN	NaN	False	bar	NaN

Assigning new columns in method chains

Inspired by `dplyr`'s `mutate` verb, DataFrame has an `assign()` method that allows you to easily create new columns that are potentially derived from existing columns.

```
In [82]: iris = pd.read_csv("data/iris.data")
```

```
In [83]: iris.head()
```

```
Out[83]:
```

	SepalLength	SepalWidth	PetalLength	PetalWidth	Name
0	5.1	3.5	1.4	0.2	Iris-setosa
1	4.9	3.0	1.4	0.2	Iris-setosa
2	4.7	3.2	1.3	0.2	Iris-setosa
3	4.6	3.1	1.5	0.2	Iris-setosa
4	5.0	3.6	1.4	0.2	Iris-setosa

```
In [84]: iris.assign(sepal_ratio=iris["SepalWidth"] / iris["SepalLength"]).head()
```

```
Out[84]:
```

	SepalLength	SepalWidth	PetalLength	PetalWidth	Name	sepal_ratio
0	5.1	3.5	1.4	0.2	Iris-setosa	0.686275
1	4.9	3.0	1.4	0.2	Iris-setosa	0.612245
2	4.7	3.2	1.3	0.2	Iris-setosa	0.680851
3	4.6	3.1	1.5	0.2	Iris-setosa	0.673913
4	5.0	3.6	1.4	0.2	Iris-setosa	0.720000

In the example above, we inserted a precomputed value. We can also pass in a function of one argument to be evaluated on the DataFrame being assigned to.

```
In [85]: iris.assign(sepal_ratio=lambda x: (x["SepalWidth"] / x["SepalLength"])).head()
```

```
Out[85]:
```

	SepalLength	SepalWidth	PetalLength	PetalWidth	Name	sepal_ratio
0	5.1	3.5	1.4	0.2	Iris-setosa	0.686275
1	4.9	3.0	1.4	0.2	Iris-setosa	0.612245
2	4.7	3.2	1.3	0.2	Iris-setosa	0.680851
3	4.6	3.1	1.5	0.2	Iris-setosa	0.673913
4	5.0	3.6	1.4	0.2	Iris-setosa	0.720000

assign always returns a copy of the data, leaving the original DataFrame untouched.

Passing a callable, as opposed to an actual value to be inserted, is useful when you don't have a reference to the DataFrame at hand. This is common when using assign in a chain of operations. For example, we can limit the DataFrame to just those observations with a Sepal Length greater than 5, calculate the ratio, and plot:

```
In [86]: (
....:     iris.query("SepalLength > 5")
....:     .assign(
....:         SepalRatio=lambda x: x.SepalWidth / x.SepalLength,
....:         PetalRatio=lambda x: x.PetalWidth / x.PetalLength,
....:     )
....:     .plot(kind="scatter", x="SepalRatio", y="PetalRatio")
....: )
```

```
Out[86]: <AxesSubplot:xlabel='SepalRatio', ylabel='PetalRatio'>
```

Since a function is passed in, the function is computed on the DataFrame being assigned to. Importantly, this is the DataFrame that's been filtered to those rows with sepal length greater than 5. The filtering happens first, and then the ratio calculations. This is an example where we didn't have a reference to the *filtered* DataFrame available.

The function signature for `assign` is simply `**kwargs`. The keys are the column names for the new fields, and the values are either a value to be inserted (for example, a Series or NumPy array), or a function of one argument to be called on the DataFrame. A *copy* of the original DataFrame is returned, with the new values inserted.

Starting with Python 3.6 the order of `**kwargs` is preserved. This allows for *dependent* assignment, where an expression later in `**kwargs` can refer to a column created earlier in the same `assign()`.

```
In [87]: dfa = pd.DataFrame({'A': [1, 2, 3], "B": [4, 5, 6]})
```

```
In [88]: dfa.assign(C=lambda x: x["A"] + x["B"], D=lambda x: x["A"] + x["C"])
```

```
Out[88]:
```

	A	B	C	D
0	1	4	5	6
1	2	5	7	9
2	3	6	9	12

In the second expression, `x['C']` will refer to the newly created column, that's equal to `dfa['A'] + dfa['B']`.

Indexing / selection

The basics of indexing are as follows:

Operation	Syntax	Result
Select column	<code>df[col]</code>	Series
Select row by label	<code>df.loc[label]</code>	Series
Select row by integer location	<code>df.iloc[loc]</code>	Series
Slice rows	<code>df[5:10]</code>	DataFrame
Select rows by boolean vector	<code>df[bool_vec]</code>	DataFrame

Row selection, for example, returns a Series whose index is the columns of the DataFrame:

```
In [89]: df.loc["b"]
```

```
Out[89]:
```

```
one      2.0
bar      2.0
flag    False
foo     bar
one_trunc  2.0
Name: b, dtype: object
```

```
In [90]: df.iloc[2]
```

```
Out[90]:
```

```
one      3.0
bar      3.0
flag    True
foo     bar
one_trunc  NaN
Name: c, dtype: object
```

For a more exhaustive treatment of sophisticated label-based indexing and slicing, see the [section on indexing](#). We will address the fundamentals of reindexing / conforming to new sets of labels in the [section on reindexing](#).

Data alignment and arithmetic

Data alignment between DataFrame objects automatically align on **both the columns and the index (row labels)**. Again, the resulting object will have the union of the column and row labels.

```
In [91]: df = pd.DataFrame(np.random.randn(10, 4), columns=["A", "B", "C", "D"])
```

```
In [92]: df2 = pd.DataFrame(np.random.randn(7, 3), columns=["A", "B", "C"])
```

```
In [93]: df + df2
```

```
Out[93]:
```

	A	B	C	D
0	0.045691	-0.014138	1.380871	NaN
1	-0.955398	-1.501007	0.037181	NaN
2	-0.662690	1.534833	-0.859691	NaN
3	-2.452949	1.237274	-0.133712	NaN
4	1.414490	1.951676	-2.320422	NaN
5	-0.494922	-1.649727	-1.084601	NaN

(continues on next page)

(continued from previous page)

```
6 -1.047551 -0.748572 -0.805479 NaN
7      NaN      NaN      NaN  NaN
8      NaN      NaN      NaN  NaN
9      NaN      NaN      NaN  NaN
```

When doing an operation between DataFrame and Series, the default behavior is to align the Series **index** on the DataFrame **columns**, thus **broadcasting** row-wise. For example:

```
In [94]: df - df.iloc[0]
Out[94]:
   A         B         C         D
0  0.000000  0.000000  0.000000  0.000000
1 -1.359261 -0.248717 -0.453372 -1.754659
2  0.253128  0.829678  0.010026 -1.991234
3 -1.311128  0.054325 -1.724913 -1.620544
4  0.573025  1.500742 -0.676070  1.367331
5 -1.741248  0.781993 -1.241620 -2.053136
6 -1.240774 -0.869551 -0.153282  0.000430
7 -0.743894  0.411013 -0.929563 -0.282386
8 -1.194921  1.320690  0.238224 -1.482644
9  2.293786  1.856228  0.773289 -1.446531
```

For explicit control over the matching and broadcasting behavior, see the section on [flexible binary operations](#).

Operations with scalars are just as you would expect:

```
In [95]: df * 5 + 2
Out[95]:
   A         B         C         D
0  3.359299 -0.124862  4.835102  3.381160
1 -3.437003 -1.368449  2.568242 -5.392133
2  4.624938  4.023526  4.885230 -6.575010
3 -3.196342  0.146766 -3.789461 -4.721559
4  6.224426  7.378849  1.454750 10.217815
5 -5.346940  3.785103 -1.373001 -6.884519
6 -2.844569 -4.472618  4.068691  3.383309
7 -0.360173  1.930201  0.187285  1.969232
8 -2.615303  6.478587  6.026220 -4.032059
9 14.828230  9.156280  8.701544 -3.851494
```

```
In [96]: 1 / df
Out[96]:
   A         B         C         D
0  3.678365 -2.353094  1.763605  3.620145
1 -0.919624 -1.484363  8.799067 -0.676395
2  1.904807  2.470934  1.732964 -0.583090
3 -0.962215 -2.697986 -0.863638 -0.743875
4  1.183593  0.929567 -9.170108  0.608434
5 -0.680555  2.800959 -1.482360 -0.562777

7 -2.118489 -71.634509 -2.758294 -162.507295
8 -1.083352  1.116424  1.241860 -0.828904
9  0.389765  0.698687  0.746097 -0.854483
```

(continues on next page)

(continued from previous page)

```
In [97]: df ** 4
Out[97]:
      A          B          C          D
0  0.005462  3.261689e-02  0.103370  5.822320e-03
1  1.398165  2.059869e-01  0.000167  4.777482e+00
2  0.075962  2.682596e-02  0.110877  8.650845e+00
3  1.166571  1.887302e-02  1.797515  3.265879e+00
4  0.509555  1.339298e+00  0.000141  7.297019e+00
5  4.661717  1.624699e-02  0.207103  9.969092e+00
6  0.881334  2.808277e+00  0.029302  5.858632e-03
7  0.049647  3.797614e-08  0.017276  1.433866e-09
8  0.725974  6.437005e-01  0.420446  2.118275e+00
9  43.329821  4.196326e+00  3.227153  1.875802e+00
```

Boolean operators work as well:

```
In [98]: df1 = pd.DataFrame({"a": [1, 0, 1], "b": [0, 1, 1]}, dtype=bool)
```

```
In [99]: df2 = pd.DataFrame({"a": [0, 1, 1], "b": [1, 1, 0]}, dtype=bool)
```

```
In [100]: df1 & df2
```

```
Out[100]:
      a      b
0  False  False
1  False  True
2  True  False
```

```
In [101]: df1 | df2
```

```
Out[101]:
      a      b
0  True  True
1  True  True
2  True  True
```

```
In [102]: df1 ^ df2
```

```
Out[102]:
      a      b
0  True  True
1  True  False
2  False  True
```

```
In [103]: -df1
```

```
Out[103]:
      a      b
0  False  True
1  True  False
2  False  False
```

Transposing

To transpose, access the `T` attribute (also the `transpose` function), similar to an ndarray:

```
# only show the first 5 rows
In [104]: df[:5].T
Out[104]:
          0         1         2         3         4
A  0.271860 -1.087401  0.524988 -1.039268  0.844885
B -0.424972 -0.673690  0.404705 -0.370647  1.075770
C  0.567020  0.113648  0.577046 -1.157892 -0.109050
D  0.276232 -1.478427 -1.715002 -1.344312  1.643563
```

DataFrame interoperability with NumPy functions

Elementwise NumPy ufuncs (log, exp, sqrt, ...) and various other NumPy functions can be used with no issues on Series and DataFrame, assuming the data within are numeric:

```
In [105]: np.exp(df)
Out[105]:
          A         B         C         D
0  1.312403  0.653788  1.763006  1.318154
1  0.337092  0.509824  1.120358  0.227996
2  1.690438  1.498861  1.780770  0.179963
3  0.353713  0.690288  0.314148  0.260719
4  2.327710  2.932249  0.896686  5.173571
5  0.230066  1.429065  0.509360  0.169161
6  0.379495  0.274028  1.512461  1.318720
7  0.623732  0.986137  0.695904  0.993865
8  0.397301  2.449092  2.237242  0.299269
9 13.009059  4.183951  3.820223  0.310274
```

```
In [106]: np.asarray(df)
Out[106]:
array([[ 0.2719, -0.425 ,  0.567 ,  0.2762],
       [-1.0874, -0.6737,  0.1136, -1.4784],
       [ 0.525 ,  0.4047,  0.577 , -1.715 ],
       [-1.0393, -0.3706, -1.1579, -1.3443],
       [ 0.8449,  1.0758, -0.109 ,  1.6436],
       [-1.4694,  0.357 , -0.6746, -1.7769],
       [-0.9689, -1.2945,  0.4137,  0.2767],
       [-0.472 , -0.014 , -0.3625, -0.0062],
       [-0.9231,  0.8957,  0.8052, -1.2064],
       [ 2.5656,  1.4313,  1.3403, -1.1703]])
```

DataFrame is not intended to be a drop-in replacement for ndarray as its indexing semantics and data model are quite different in places from an n-dimensional array.

`Series` implements `__array_ufunc__`, which allows it to work with NumPy's universal functions.

The ufunc is applied to the underlying array in a Series.

```
In [107]: ser = pd.Series([1, 2, 3, 4])
```

(continues on next page)

(continued from previous page)

In [108]: np.exp(ser)**Out[108]:**

```
0    2.718282
1    7.389056
2   20.085537
3   54.598150
dtype: float64
```

Changed in version 0.25.0: When multiple *Series* are passed to a ufunc, they are aligned before performing the operation.

Like other parts of the library, pandas will automatically align labeled inputs as part of a ufunc with multiple inputs. For example, using `numpy.remainder()` on two *Series* with differently ordered labels will align before the operation.

In [109]: ser1 = pd.Series([1, 2, 3], index=["a", "b", "c"])**In [110]:** ser2 = pd.Series([1, 3, 5], index=["b", "a", "c"])**In [111]:** ser1**Out[111]:**

```
a    1
b    2
c    3
dtype: int64
```

In [112]: ser2**Out[112]:**

```
b    1
a    3
c    5
dtype: int64
```

In [113]: np.remainder(ser1, ser2)**Out[113]:**

```
a    1
b    0
c    3
dtype: int64
```

As usual, the union of the two indices is taken, and non-overlapping values are filled with missing values.

In [114]: ser3 = pd.Series([2, 4, 6], index=["b", "c", "d"])**In [115]:** ser3**Out[115]:**

```
b    2
c    4
d    6
dtype: int64
```

In [116]: np.remainder(ser1, ser3)**Out[116]:**

```
a    NaN
```

(continues on next page)

(continued from previous page)

```
b    0.0
c    3.0
d    NaN
dtype: float64
```

When a binary ufunc is applied to a `Series` and `Index`, the Series implementation takes precedence and a Series is returned.

```
In [117]: ser = pd.Series([1, 2, 3])

In [118]: idx = pd.Index([4, 5, 6])

In [119]: np.maximum(ser, idx)
Out[119]:
0    4
1    5
2    6
dtype: int64
```

NumPy ufuncs are safe to apply to `Series` backed by non-ndarray arrays, for example `arrays.SparseArray` (see *Sparse calculation*). If possible, the ufunc is applied without converting the underlying data to an ndarray.

Console display

Very large DataFrames will be truncated to display them in the console. You can also get a summary using `info()`. (Here I am reading a CSV version of the `baseball` dataset from the `plyr` R package):

```
In [120]: baseball = pd.read_csv("data/baseball.csv")

In [121]: print(baseball)
      id   player  year  stint team lg  g  ab  r   h  X2b  X3b  hr  rbi  sb
      cs   bb   so   ibb  hbp   sh   sf  gidp
0  88641  womacto01  2006      2  CHN  NL  19  50  6  14  1   0   1  2.0  1.0  1.
0   4   4.0  0.0  0.0  3.0  0.0  0.0
1  88643  schilcu01  2006      1  BOS  AL  31  2   0   1   0   0   0  0.0  0.0  0.
0   0   1.0  0.0  0.0  0.0  0.0  0.0
...
98 89533  aloumo01  2007      1  NYN  NL  87  328  51  112  19   1  13  49.0  3.0  0.
0   27  30.0  5.0  2.0  0.0  3.0  13.0
99 89534  alomasa02  2007      1  NYN  NL   8  22   1   3   1   0   0  0.0  0.0  0.
0   0   3.0  0.0  0.0  0.0  0.0  0.0
[100 rows x 23 columns]
```

```
In [122]: baseball.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 100 entries, 0 to 99
Data columns (total 23 columns):
 #   Column  Non-Null Count  Dtype  
---  -- 
 0   id      100 non-null   int64

dtypes: float64(9), int64(11), object(3)
memory usage: 18.1+ KB

```

However, using `to_string` will return a string representation of the DataFrame in tabular form, though it won't always fit the console width:

```
In [123]: print(baseball.iloc[-20:, :12].to_string())
      id    player  year  stint  team  lg    g  ab    r    h   X2b   X3b

```

Wide DataFrames will be printed across multiple rows by default:

```
In [124]: pd.DataFrame(np.random.randn(3, 12))
Out[124]:
          0         1         2         3         4         5         6         7
0 -1.226825  0.769804 -1.281247 -0.727707 -0.121306 -0.097883  0.695775  0.341734  0.
   ↵959726 -1.110336 -0.619976  0.149748
1 -0.732339  0.687738  0.176444  0.403310 -0.154951  0.301624 -2.179861 -1.369849 -0.
   ↵954208  1.462696 -1.743161 -0.826591
2 -0.345352  1.314232  0.690579  0.995761  2.396780  0.014871  3.357427 -0.317441 -1.
   ↵236269  0.896171 -0.487602 -0.082240
```

You can change how much to print on a single row by setting the `display.width` option:

```
In [125]: pd.set_option("display.width", 40) # default is 80
In [126]: pd.DataFrame(np.random.randn(3, 12))
Out[126]:
          0         1         2         3         4         5         6         7
0 -2.182937  0.380396  0.084844  0.432390  1.519970 -0.493662  0.600178  0.274230  0.
   ↵132885 -0.023688  2.410179  1.450520
1  0.206053 -0.251905 -2.213588  1.063327  1.266143  0.299368 -0.863838  0.408204 -1.
   ↵048089 -0.025747 -0.988387  0.094055
2  1.262731  1.289997  0.082423 -0.055758  0.536580 -0.489682  0.369374 -0.034571 -2.
   ↵484478 -0.281461  0.030711  0.109121
```

You can adjust the max width of the individual columns by setting `display.max_colwidth`

```
In [127]: datafile = {
    ....:     "filename": ["filename_01", "filename_02"],
    ....:     "path": [
    ....:         "media/user_name/storage/folder_01/filename_01",
    ....:         "media/user_name/storage/folder_02/filename_02",
    ....:     ],
    ....: }
    ....:

In [128]: pd.set_option("display.max_colwidth", 30)
In [129]: pd.DataFrame(datafile)
Out[129]:
      filename                  path
0  filename_01  media/user_name/storage/fo...
1  filename_02  media/user_name/storage/fo...

In [130]: pd.set_option("display.max_colwidth", 100)
In [131]: pd.DataFrame(datafile)
Out[131]:
      filename                  path
0  filename_01  media/user_name/storage/folder_01/filename_01
1  filename_02  media/user_name/storage/folder_02/filename_02
```

You can also disable this feature via the `expand_frame_repr` option. This will print the table in one block.

DataFrame column attribute access and IPython completion

If a DataFrame column label is a valid Python variable name, the column can be accessed like an attribute:

```
In [132]: df = pd.DataFrame({"foo1": np.random.randn(5), "foo2": np.random.randn(5)})
```

```
In [133]: df
```

```
Out[133]:
```

```
    foo1      foo2
0  1.126203  0.781836
1 -0.977349 -1.071357
2  1.474071  0.441153
3 -0.064034  2.353925
4 -1.282782  0.583787
```

```
In [134]: df.foo1
```

```
Out[134]:
```

```
0      1.126203
1     -0.977349
2      1.474071
3     -0.064034
4     -1.282782
Name: foo1, dtype: float64
```

The columns are also connected to the IPython completion mechanism so they can be tab-completed:

```
In [5]: df.foo<TAB> # noqa: E225, E999
df.foo1  df.foo2
```

2.3 Essential basic functionality

Here we discuss a lot of the essential functionality common to the pandas data structures. To begin, let's create some example objects like we did in the *10 minutes to pandas* section:

```
In [1]: index = pd.date_range("1/1/2000", periods=8)
```

```
In [2]: s = pd.Series(np.random.randn(5), index=["a", "b", "c", "d", "e"])
```

```
In [3]: df = pd.DataFrame(np.random.randn(8, 3), index=index, columns=["A", "B", "C"])
```

2.3.1 Head and tail

To view a small sample of a Series or DataFrame object, use the `head()` and `tail()` methods. The default number of elements to display is five, but you may pass a custom number.

```
In [4]: long_series = pd.Series(np.random.randn(1000))
```

```
In [5]: long_series.head()
```

```
Out[5]:
```

```
0     -1.157892
```

(continues on next page)

(continued from previous page)

```
1   -1.344312
2    0.844885
3    1.075770
4   -0.109050
dtype: float64
```

In [6]: long_series.tail(3)

Out[6]:

```
997  -0.289388
998  -1.020544
999   0.589993
dtype: float64
```

2.3.2 Attributes and underlying data

pandas objects have a number of attributes enabling you to access the metadata

- **shape:** gives the axis dimensions of the object, consistent with ndarray
- **Axis labels**
 - **Series:** *index* (only axis)
 - **DataFrame:** *index* (rows) and *columns*

Note, **these attributes can be safely assigned to!**

In [7]: df[:2]

Out[7]:

	A	B	C
2000-01-01	-0.173215	0.119209	-1.044236
2000-01-02	-0.861849	-2.104569	-0.494929

In [8]: df.columns = [x.lower() for x in df.columns]

In [9]: df

Out[9]:

	a	b	c
2000-01-01	-0.173215	0.119209	-1.044236
2000-01-02	-0.861849	-2.104569	-0.494929
2000-01-03	1.071804	0.721555	-0.706771
2000-01-04	-1.039575	0.271860	-0.424972
2000-01-05	0.567020	0.276232	-1.087401
2000-01-06	-0.673690	0.113648	-1.478427
2000-01-07	0.524988	0.404705	0.577046
2000-01-08	-1.715002	-1.039268	-0.370647

pandas objects (*Index*, *Series*, *DataFrame*) can be thought of as containers for arrays, which hold the actual data and do the actual computation. For many types, the underlying array is a `numpy.ndarray`. However, pandas and 3rd party libraries may *extend* NumPy's type system to add support for custom arrays (see *dtypes*).

To get the actual data inside a *Index* or *Series*, use the `.array` property

```
In [10]: s.array
Out[10]:
<PandasArray>
[ 0.4691122999071863, -0.2828633443286633, -1.5090585031735124,
 -1.1356323710171934,  1.2121120250208506]
Length: 5, dtype: float64

In [11]: s.index.array
Out[11]:
<PandasArray>
['a', 'b', 'c', 'd', 'e']
Length: 5, dtype: object
```

`array` will always be an `ExtensionArray`. The exact details of what an `ExtensionArray` is and why pandas uses them are a bit beyond the scope of this introduction. See [dtypes](#) for more.

If you know you need a NumPy array, use `to_numpy()` or `numpy.asarray()`.

```
In [12]: s.to_numpy()
Out[12]: array([ 0.4691, -0.2829, -1.5091, -1.1356,  1.2121])

In [13]: np.asarray(s)
Out[13]: array([ 0.4691, -0.2829, -1.5091, -1.1356,  1.2121])
```

When the Series or Index is backed by an `ExtensionArray`, `to_numpy()` may involve copying data and coercing values. See [dtypes](#) for more.

`to_numpy()` gives some control over the `dtype` of the resulting `numpy.ndarray`. For example, consider datetimes with timezones. NumPy doesn't have a `dtype` to represent timezone-aware datetimes, so there are two possibly useful representations:

1. An object-dtype `numpy.ndarray` with `Timestamp` objects, each with the correct `tz`
2. A `datetime64[ns]`-dtype `numpy.ndarray`, where the values have been converted to UTC and the timezone discarded

Timezones may be preserved with `dtype=object`

```
In [14]: ser = pd.Series(pd.date_range("2000", periods=2, tz="CET"))

In [15]: ser.to_numpy(dtype=object)
Out[15]:
array([Timestamp('2000-01-01 00:00:00+0100', tz='CET'),
       Timestamp('2000-01-02 00:00:00+0100', tz='CET')], dtype=object)
```

Or thrown away with `dtype='datetime64[ns]'`

```
In [16]: ser.to_numpy(dtype="datetime64[ns]")
Out[16]:
array(['1999-12-31T23:00:00.000000000', '2000-01-01T23:00:00.000000000'],
      dtype='datetime64[ns]')
```

Getting the “raw data” inside a `DataFrame` is possibly a bit more complex. When your `DataFrame` only has a single data type for all the columns, `DataFrame.to_numpy()` will return the underlying data:

```
In [17]: df.to_numpy()
Out[17]:
array([[-0.1732,  0.1192, -1.0442],
       [-0.8618, -2.1046, -0.4949],
       [ 1.0718,  0.7216, -0.7068],
       [-1.0396,  0.2719, -0.425 ],
       [ 0.567 ,  0.2762, -1.0874],
       [-0.6737,  0.1136, -1.4784],
       [ 0.525 ,  0.4047,  0.577 ],
       [-1.715 , -1.0393, -0.3706]])
```

If a DataFrame contains homogeneously-typed data, the ndarray can actually be modified in-place, and the changes will be reflected in the data structure. For heterogeneous data (e.g. some of the DataFrame's columns are not all the same dtype), this will not be the case. The values attribute itself, unlike the axis labels, cannot be assigned to.

Note: When working with heterogeneous data, the dtype of the resulting ndarray will be chosen to accommodate all of the data involved. For example, if strings are involved, the result will be of object dtype. If there are only floats and integers, the resulting array will be of float dtype.

In the past, pandas recommended `Series.values` or `DataFrame.values` for extracting the data from a Series or DataFrame. You'll still find references to these in old code bases and online. Going forward, we recommend avoiding `.values` and using `.array` or `.to_numpy()`. `.values` has the following drawbacks:

1. When your Series contains an *extension type*, it's unclear whether `Series.values` returns a NumPy array or the extension array. `Series.array` will always return an `ExtensionArray`, and will never copy data. `Series.to_numpy()` will always return a NumPy array, potentially at the cost of copying / coercing values.
2. When your DataFrame contains a mixture of data types, `DataFrame.values` may involve copying data and coercing values to a common dtype, a relatively expensive operation. `DataFrame.to_numpy()`, being a method, makes it clearer that the returned NumPy array may not be a view on the same data in the DataFrame.

2.3.3 Accelerated operations

pandas has support for accelerating certain types of binary numerical and boolean operations using the `numexpr` library and the `bottleneck` libraries.

These libraries are especially useful when dealing with large data sets, and provide large speedups. `numexpr` uses smart chunking, caching, and multiple cores. `bottleneck` is a set of specialized cython routines that are especially fast when dealing with arrays that have nans.

Here is a sample (using 100 column x 100,000 row DataFrames):

Operation	0.11.0 (ms)	Prior Version (ms)	Ratio to Prior
<code>df1 > df2</code>	13.32	125.35	0.1063
<code>df1 * df2</code>	21.71	36.63	0.5928
<code>df1 + df2</code>	22.04	36.50	0.6039

You are highly encouraged to install both libraries. See the section *Recommended Dependencies* for more installation info.

These are both enabled to be used by default, you can control this by setting the options:

```
pd.set_option("compute.use_bottleneck", False)
pd.set_option("compute.use_numexpr", False)
```

2.3.4 Flexible binary operations

With binary operations between pandas data structures, there are two key points of interest:

- Broadcasting behavior between higher- (e.g. DataFrame) and lower-dimensional (e.g. Series) objects.
- Missing data in computations.

We will demonstrate how to manage these issues independently, though they can be handled simultaneously.

Matching / broadcasting behavior

DataFrame has the methods `add()`, `sub()`, `mul()`, `div()` and related functions `radd()`, `rsub()`, ... for carrying out binary operations. For broadcasting behavior, Series input is of primary interest. Using these functions, you can use to either match on the `index` or `columns` via the `axis` keyword:

```
In [18]: df = pd.DataFrame(
    ....:
    ....:     {
    ....:         "one": pd.Series(np.random.randn(3), index=["a", "b", "c"]),
    ....:         "two": pd.Series(np.random.randn(4), index=["a", "b", "c", "d"]),
    ....:         "three": pd.Series(np.random.randn(3), index=["b", "c", "d"]),
    ....:     }
    ....:
....:
```

In [19]: df
Out[19]:

	one	two	three
a	1.394981	1.772517	NaN
b	0.343054	1.912123	-0.050390
c	0.695246	1.478369	1.227435
d	NaN	0.279344	-0.613172

In [20]: row = df.iloc[1]

In [21]: column = df["two"]

In [22]: df.sub(row, axis="columns")
Out[22]:

	one	two	three
a	1.051928	-0.139606	NaN
b	0.000000	0.000000	0.000000
c	0.352192	-0.433754	1.277825
d	NaN	-1.632779	-0.562782

In [23]: df.sub(row, axis=1)
Out[23]:

	one	two	three
a	1.051928	-0.139606	NaN

(continues on next page)

(continued from previous page)

```
b  0.000000  0.000000  0.000000
c  0.352192 -0.433754  1.277825
d      NaN -1.632779 -0.562782
```

In [24]: df.sub(column, axis="index")

Out[24]:

	one	two	three
a	-0.377535	0.0	NaN
b	-1.569069	0.0	-1.962513
c	-0.783123	0.0	-0.250933
d	NaN	0.0	-0.892516

In [25]: df.sub(column, axis=0)

Out[25]:

	one	two	three
a	-0.377535	0.0	NaN
b	-1.569069	0.0	-1.962513
c	-0.783123	0.0	-0.250933
d	NaN	0.0	-0.892516

Furthermore you can align a level of a MultiIndexed DataFrame with a Series.

In [26]: dfmi = df.copy()

In [27]: dfmi.index = pd.MultiIndex.from_tuples(
....: [(1, "a"), (1, "b"), (1, "c"), (2, "a")], names=["first", "second"]
....:)
....:

In [28]: dfmi.sub(column, axis=0, level="second")

Out[28]:

	one	two	three
first second			
1 a	-0.377535	0.000000	NaN
b	-1.569069	0.000000	-1.962513
c	-0.783123	0.000000	-0.250933
2 a	NaN	-1.493173	-2.385688

Series and Index also support the `divmod()` builtin. This function takes the floor division and modulo operation at the same time returning a two-tuple of the same type as the left hand side. For example:

In [29]: s = pd.Series(np.arange(10))

In [30]: s

Out[30]:

0	0
1	1
2	2
3	3
4	4
5	5
6	6

(continues on next page)

(continued from previous page)

```
7    7  
8    8  
9    9  
dtype: int64
```

```
In [31]: div, rem = divmod(s, 3)
```

```
In [32]: div
```

```
Out[32]:
```

```
0    0  
1    0  
2    0  
3    1  
4    1  
5    1  
6    2  
7    2  
8    2  
9    3  
dtype: int64
```

```
In [33]: rem
```

```
Out[33]:
```

```
0    0  
1    1  
2    2  
3    0  
4    1  
5    2  
6    0  
7    1  
8    2  
9    0  
dtype: int64
```

```
In [34]: idx = pd.Index(np.arange(10))
```

```
In [35]: idx
```

```
Out[35]: Int64Index([0, 1, 2, 3, 4, 5, 6, 7, 8, 9], dtype='int64')
```

```
In [36]: div, rem = divmod(idx, 3)
```

```
In [37]: div
```

```
Out[37]: Int64Index([0, 0, 0, 1, 1, 1, 2, 2, 2, 3], dtype='int64')
```

```
In [38]: rem
```

```
Out[38]: Int64Index([0, 1, 2, 0, 1, 2, 0, 1, 2, 0], dtype='int64')
```

We can also do elementwise `divmod()`:

```
In [39]: div, rem = divmod(s, [2, 2, 3, 3, 4, 4, 5, 5, 6, 6])
```

(continues on next page)

(continued from previous page)

In [40]: div**Out[40]:**

```
0    0
1    0
2    0
3    1
4    1
5    1
6    1
7    1
8    1
9    1
dtype: int64
```

In [41]: rem**Out[41]:**

```
0    0
1    1
2    2
3    0
4    0
5    1
6    1
7    2
8    2
9    3
dtype: int64
```

Missing data / operations with fill values

In Series and DataFrame, the arithmetic functions have the option of inputting a *fill_value*, namely a value to substitute when at most one of the values at a location are missing. For example, when adding two DataFrame objects, you may wish to treat NaN as 0 unless both DataFrames are missing that value, in which case the result will be NaN (you can later replace NaN with some other value using `fillna` if you wish).

In [42]: df**Out[42]:**

	one	two	three
a	1.394981	1.772517	NaN
b	0.343054	1.912123	-0.050390
c	0.695246	1.478369	1.227435
d	NaN	0.279344	-0.613172

In [43]: df2**Out[43]:**

	one	two	three
a	1.394981	1.772517	1.000000
b	0.343054	1.912123	-0.050390
c	0.695246	1.478369	1.227435
d	NaN	0.279344	-0.613172

(continues on next page)

(continued from previous page)

In [44]: df + df2**Out[44]:**

```
one      two      three
a  2.789963  3.545034      NaN
b  0.686107  3.824246 -0.100780
c  1.390491  2.956737  2.454870
d      NaN  0.558688 -1.226343
```

In [45]: df.add(df2, fill_value=0)**Out[45]:**

```
one      two      three
a  2.789963  3.545034  1.000000
b  0.686107  3.824246 -0.100780
c  1.390491  2.956737  2.454870
d      NaN  0.558688 -1.226343
```

Flexible comparisons

Series and DataFrame have the binary comparison methods `eq`, `ne`, `lt`, `gt`, `le`, and `ge` whose behavior is analogous to the binary arithmetic operations described above:

In [46]: df.gt(df2)**Out[46]:**

```
one      two      three
a  False  False  False
b  False  False  False
c  False  False  False
d  False  False  False
```

In [47]: df2.ne(df)**Out[47]:**

```
one      two      three
a  False  False   True
b  False  False  False
c  False  False  False
d   True  False  False
```

These operations produce a pandas object of the same type as the left-hand-side input that is of dtype `bool`. These boolean objects can be used in indexing operations, see the section on [Boolean indexing](#).

Boolean reductions

You can apply the reductions: `empty`, `any()`, `all()`, and `bool()` to provide a way to summarize a boolean result.

In [48]: (df > 0).all()**Out[48]:**

```
one      False
two      True
three    False
dtype: bool
```

(continues on next page)

(continued from previous page)

In [49]: `(df > 0).any()`**Out[49]:**

```
one      True
two      True
three    True
dtype: bool
```

You can reduce to a final boolean value.

In [50]: `(df > 0).any().any()`**Out[50]:** True

You can test if a pandas object is empty, via the `empty` property.

In [51]: `df.empty`**Out[51]:** False**In [52]:** `pd.DataFrame(columns=list("ABC")).empty`**Out[52]:** True

To evaluate single-element pandas objects in a boolean context, use the method `bool()`:

In [53]: `pd.Series([True]).bool()`**Out[53]:** True**In [54]:** `pd.Series([False]).bool()`**Out[54]:** False**In [55]:** `pd.DataFrame([[True]]).bool()`**Out[55]:** True**In [56]:** `pd.DataFrame([[False]]).bool()`**Out[56]:** False

Warning: You might be tempted to do the following:

```
>>> if df:
...     pass
```

Or

```
>>> df and df2
```

These will both raise errors, as you are trying to compare multiple values.:

```
ValueError: The truth value of an array is ambiguous. Use a.empty, a.any() or a.all().
```

See [gotchas](#) for a more detailed discussion.

Comparing if objects are equivalent

Often you may find that there is more than one way to compute the same result. As a simple example, consider `df + df` and `df * 2`. To test that these two computations produce the same result, given the tools shown above, you might imagine using `(df + df == df * 2).all()`. But in fact, this expression is False:

```
In [57]: df + df == df * 2
```

```
Out[57]:
```

```
one    two    three
a    True   True   False
b    True   True    True
c    True   True    True
d   False  True    True
```

```
In [58]: (df + df == df * 2).all()
```

```
Out[58]:
```

```
one      False
two      True
three    False
dtype: bool
```

Notice that the boolean DataFrame `df + df == df * 2` contains some False values! This is because NaNs do not compare as equals:

```
In [59]: np.nan == np.nan
```

```
Out[59]: False
```

So, NDFrames (such as Series and DataFrames) have an `equals()` method for testing equality, with NaNs in corresponding locations treated as equal.

```
In [60]: (df + df).equals(df * 2)
```

```
Out[60]: True
```

Note that the Series or DataFrame index needs to be in the same order for equality to be True:

```
In [61]: df1 = pd.DataFrame({"col": ["foo", 0, np.nan]})
```

```
In [62]: df2 = pd.DataFrame({"col": [np.nan, 0, "foo"]}, index=[2, 1, 0])
```

```
In [63]: df1.equals(df2)
```

```
Out[63]: False
```

```
In [64]: df1.equals(df2.sort_index())
```

```
Out[64]: True
```

Comparing array-like objects

You can conveniently perform element-wise comparisons when comparing a pandas data structure with a scalar value:

```
In [65]: pd.Series(["foo", "bar", "baz"]) == "foo"
```

```
Out[65]:
```

```
0    True
1   False
2   False
dtype: bool
```

```
In [66]: pd.Index(["foo", "bar", "baz"]) == "foo"
```

```
Out[66]: array([ True, False, False])
```

pandas also handles element-wise comparisons between different array-like objects of the same length:

```
In [67]: pd.Series(["foo", "bar", "baz"]) == pd.Index(["foo", "bar", "qux"])
```

```
Out[67]:
```

```
0    True
1    True
2   False
dtype: bool
```

```
In [68]: pd.Series(["foo", "bar", "baz"]) == np.array(["foo", "bar", "qux"])
```

```
Out[68]:
```

```
0    True
1    True
2   False
dtype: bool
```

Trying to compare Index or Series objects of different lengths will raise a ValueError:

```
In [55]: pd.Series(['foo', 'bar', 'baz']) == pd.Series(['foo', 'bar'])
```

```
ValueError: Series lengths must match to compare
```

```
In [56]: pd.Series(['foo', 'bar', 'baz']) == pd.Series(['foo'])
```

```
ValueError: Series lengths must match to compare
```

Note that this is different from the NumPy behavior where a comparison can be broadcast:

```
In [69]: np.array([1, 2, 3]) == np.array([2])
```

```
Out[69]: array([False,  True, False])
```

or it can return False if broadcasting can not be done:

```
In [70]: np.array([1, 2, 3]) == np.array([1, 2])
```

```
Out[70]: False
```

Combining overlapping data sets

A problem occasionally arising is the combination of two similar data sets where values in one are preferred over the other. An example would be two data series representing a particular economic indicator where one is considered to be of “higher quality”. However, the lower quality series might extend further back in history or have more complete data coverage. As such, we would like to combine two DataFrame objects where missing values in one DataFrame are conditionally filled with like-labeled values from the other DataFrame. The function implementing this operation is `combine_first()`, which we illustrate:

```
In [71]: df1 = pd.DataFrame(  
....:     {"A": [1.0, np.nan, 3.0, 5.0, np.nan], "B": [np.nan, 2.0, 3.0, np.nan, 6.0]}  
....:  
....:  
In [72]: df2 = pd.DataFrame(  
....:     {  
....:         "A": [5.0, 2.0, 4.0, np.nan, 3.0, 7.0],  
....:         "B": [np.nan, np.nan, 3.0, 4.0, 6.0, 8.0],  
....:     }  
....:  
....:  
In [73]: df1  
Out[73]:  
      A    B  
0  1.0  NaN  
1  NaN  2.0  
2  3.0  3.0  
3  5.0  NaN  
4  NaN  6.0  
  
In [74]: df2  
Out[74]:  
      A    B  
0  5.0  NaN  
1  2.0  NaN  
2  4.0  3.0  
3  NaN  4.0  
4  3.0  6.0  
5  7.0  8.0  
  
In [75]: df1.combine_first(df2)  
Out[75]:  
      A    B  
0  1.0  NaN  
1  2.0  2.0  
2  3.0  3.0  
3  5.0  4.0  
4  3.0  6.0  
5  7.0  8.0
```

General DataFrame combine

The `combine_first()` method above calls the more general `DataFrame.combine()`. This method takes another DataFrame and a combiner function, aligns the input DataFrame and then passes the combiner function pairs of Series (i.e., columns whose names are the same).

So, for instance, to reproduce `combine_first()` as above:

```
In [76]: def combiner(x, y):
....:     return np.where(pd.isna(x), y, x)
....:
```

```
In [77]: df1.combine(df2, combiner)
```

```
Out[77]:
```

	A	B
0	1.0	NaN
1	2.0	2.0
2	3.0	3.0
3	5.0	4.0
4	3.0	6.0
5	7.0	8.0

2.3.5 Descriptive statistics

There exists a large number of methods for computing descriptive statistics and other related operations on `Series`, `DataFrame`. Most of these are aggregations (hence producing a lower-dimensional result) like `sum()`, `mean()`, and `quantile()`, but some of them, like `cumsum()` and `cumprod()`, produce an object of the same size. Generally speaking, these methods take an `axis` argument, just like `ndarray.{sum, std, ...}`, but the axis can be specified by name or integer:

- **Series**: no axis argument needed
- **DataFrame**: “index” (axis=0, default), “columns” (axis=1)

For example:

```
In [78]: df
Out[78]:
```

	one	two	three
a	1.394981	1.772517	NaN
b	0.343054	1.912123	-0.050390
c	0.695246	1.478369	1.227435
d	NaN	0.279344	-0.613172

```
In [79]: df.mean(0)
```

```
Out[79]:
```

	one	two	three
one	0.811094		
two		1.360588	
three		0.187958	
dtype: float64			

```
In [80]: df.mean(1)
```

```
Out[80]:
```

	a
a	1.583749

(continues on next page)

(continued from previous page)

```
b    0.734929
c    1.133683
d   -0.166914
dtype: float64
```

All such methods have a `skipna` option signaling whether to exclude missing data (True by default):

In [81]: `df.sum(0, skipna=False)`

Out[81]:

```
one      NaN
two     5.442353
three    NaN
dtype: float64
```

In [82]: `df.sum(axis=1, skipna=True)`

Out[82]:

```
a    3.167498
b    2.204786
c    3.401050
d   -0.333828
dtype: float64
```

Combined with the broadcasting / arithmetic behavior, one can describe various statistical procedures, like standardization (rendering data zero mean and standard deviation of 1), very concisely:

In [83]: `ts_stand = (df - df.mean()) / df.std()`

In [84]: `ts_stand.std()`

Out[84]:

```
one    1.0
two    1.0
three  1.0
dtype: float64
```

In [85]: `xs_stand = df.sub(df.mean(1), axis=0).div(df.std(1), axis=0)`

In [86]: `xs_stand.std(1)`

Out[86]:

```
a    1.0
b    1.0
c    1.0
d    1.0
dtype: float64
```

Note that methods like `cumsum()` and `cumprod()` preserve the location of `NaN` values. This is somewhat different from `expanding()` and `rolling()` since `NaN` behavior is furthermore dictated by a `min_periods` parameter.

In [87]: `df.cumsum()`

Out[87]:

	one	two	three
a	1.394981	1.772517	NaN
b	1.738035	3.684640	-0.050390

(continues on next page)

(continued from previous page)

c	2.433281	5.163008	1.177045
d		NaN	5.442353 0.563873

Here is a quick reference summary table of common functions. Each also takes an optional `level` parameter which applies only if the object has a *hierarchical index*.

Function	Description
<code>count</code>	Number of non-NA observations
<code>sum</code>	Sum of values
<code>mean</code>	Mean of values
<code>mad</code>	Mean absolute deviation
<code>median</code>	Arithmetic median of values
<code>min</code>	Minimum
<code>max</code>	Maximum
<code>mode</code>	Mode
<code>abs</code>	Absolute Value
<code>prod</code>	Product of values
<code>std</code>	Bessel-corrected sample standard deviation
<code>var</code>	Unbiased variance
<code>sem</code>	Standard error of the mean
<code>skew</code>	Sample skewness (3rd moment)
<code>kurt</code>	Sample kurtosis (4th moment)
<code>quantile</code>	Sample quantile (value at %)
<code>cumsum</code>	Cumulative sum
<code>cumprod</code>	Cumulative product
<code>cummax</code>	Cumulative maximum
<code>cummin</code>	Cumulative minimum

Note that by chance some NumPy methods, like `mean`, `std`, and `sum`, will exclude NAs on Series input by default:

```
In [88]: np.mean(df["one"])
Out[88]: 0.8110935116651192
```

```
In [89]: np.mean(df["one"].to_numpy())
Out[89]: nan
```

`Series.nunique()` will return the number of unique non-NA values in a Series:

```
In [90]: series = pd.Series(np.random.randn(500))

In [91]: series[20:500] = np.nan

In [92]: series[10:20] = 5

In [93]: series.nunique()
Out[93]: 11
```

Summarizing data: describe

There is a convenient `describe()` function which computes a variety of summary statistics about a Series or the columns of a DataFrame (excluding NAs of course):

```
In [94]: series = pd.Series(np.random.randn(1000))
```

```
In [95]: series[::2] = np.nan
```

```
In [96]: series.describe()
```

```
Out[96]:
```

```
count    500.000000
mean     -0.021292
std      1.015906
min     -2.683763
25%     -0.699070
50%     -0.069718
75%      0.714483
max      3.160915
dtype: float64
```

```
In [97]: frame = pd.DataFrame(np.random.randn(1000, 5), columns=["a", "b", "c", "d", "e"])
          ↵ ])
```

```
In [98]: frame.iloc[::2] = np.nan
```

```
In [99]: frame.describe()
```

```
Out[99]:
```

	a	b	c	d	e
count	500.000000	500.000000	500.000000	500.000000	500.000000
mean	0.033387	0.030045	-0.043719	-0.051686	0.005979
std	1.017152	0.978743	1.025270	1.015988	1.006695
min	-3.000951	-2.637901	-3.303099	-3.159200	-3.188821
25%	-0.647623	-0.576449	-0.712369	-0.691338	-0.691115
50%	0.047578	-0.021499	-0.023888	-0.032652	-0.025363
75%	0.729907	0.775880	0.618896	0.670047	0.649748
max	2.740139	2.752332	3.004229	2.728702	3.240991

You can select specific percentiles to include in the output:

```
In [100]: series.describe(percentiles=[0.05, 0.25, 0.75, 0.95])
```

```
Out[100]:
```

```
count    500.000000
mean     -0.021292
std      1.015906
min     -2.683763
5%      -1.645423
25%     -0.699070
50%     -0.069718
75%      0.714483
95%      1.711409
max      3.160915
dtype: float64
```

By default, the median is always included.

For a non-numerical Series object, `describe()` will give a simple summary of the number of unique values and most frequently occurring values:

```
In [101]: s = pd.Series(["a", "a", "b", "b", "a", "a", np.nan, "c", "d", "a"])
```

```
In [102]: s.describe()
```

```
Out[102]:
```

count	9
unique	4
top	a
freq	5
dtype:	object

Note that on a mixed-type DataFrame object, `describe()` will restrict the summary to include only numerical columns or, if none are, only categorical columns:

```
In [103]: frame = pd.DataFrame({"a": ["Yes", "Yes", "No", "No"], "b": range(4)})
```

```
In [104]: frame.describe()
```

```
Out[104]:
```

	b
count	4.000000
mean	1.500000
std	1.290994
min	0.000000
25%	0.750000
50%	1.500000
75%	2.250000
max	3.000000

This behavior can be controlled by providing a list of types as `include/exclude` arguments. The special value `all` can also be used:

```
In [105]: frame.describe(include=["object"])
```

```
Out[105]:
```

	a
count	4
unique	2
top	Yes
freq	2

```
In [106]: frame.describe(include=["number"])
```

```
Out[106]:
```

	b
count	4.000000
mean	1.500000
std	1.290994
min	0.000000
25%	0.750000
50%	1.500000
75%	2.250000
max	3.000000

(continues on next page)

(continued from previous page)

```
In [107]: frame.describe(include="all")
Out[107]:
      a          b
count    4  4.000000
unique   2      NaN
top     Yes      NaN
freq     2      NaN
mean    NaN  1.500000
std     NaN  1.290994
min    NaN  0.000000
25%    NaN  0.750000
50%    NaN  1.500000
75%    NaN  2.250000
max    NaN  3.000000
```

That feature relies on `select_dtypes`. Refer to there for details about accepted inputs.

Index of min/max values

The `idxmin()` and `idxmax()` functions on Series and DataFrame compute the index labels with the minimum and maximum corresponding values:

```
In [108]: s1 = pd.Series(np.random.randn(5))

In [109]: s1
Out[109]:
0    1.118076
1   -0.352051
2   -1.242883
3   -1.277155
4   -0.641184
dtype: float64

In [110]: s1.idxmin(), s1.idxmax()
Out[110]: (3, 0)

In [111]: df1 = pd.DataFrame(np.random.randn(5, 3), columns=["A", "B", "C"])

In [112]: df1
Out[112]:
      A          B          C
0 -0.327863 -0.946180 -0.137570
1 -0.186235 -0.257213 -0.486567
2 -0.507027 -0.871259 -0.111110
3  2.000339 -2.430505  0.089759
4 -0.321434 -0.033695  0.096271

In [113]: df1.idxmin(axis=0)
Out[113]:
A    2
```

(continues on next page)

(continued from previous page)

```
B    3
C    1
dtype: int64

In [114]: df1.idxmax(axis=1)
Out[114]:
0    C
1    A
2    C
3    A
4    C
dtype: object
```

When there are multiple rows (or columns) matching the minimum or maximum value, `idxmin()` and `idxmax()` return the first matching index:

```
In [115]: df3 = pd.DataFrame([2, 1, 1, 3, np.nan], columns=["A"], index=list("edcba"))

In [116]: df3
Out[116]:
      A
e  2.0
d  1.0
c  1.0
b  3.0
a  NaN

In [117]: df3["A"].idxmin()
Out[117]: 'd'
```

Note: `idxmin` and `idxmax` are called `argmin` and `argmax` in NumPy.

Value counts (histogramming) / mode

The `value_counts()` Series method and top-level function computes a histogram of a 1D array of values. It can also be used as a function on regular arrays:

```
In [118]: data = np.random.randint(0, 7, size=50)

In [119]: data
Out[119]:
array([6, 6, 2, 3, 5, 3, 2, 5, 4, 5, 4, 3, 4, 5, 5, 0, 2, 0, 4, 2, 0,
       3, 2, 5, 6, 5, 3, 4, 6, 4, 3, 5, 6, 4, 3, 6, 2, 6, 6, 2, 3, 4, 2, 1,
       6, 2, 6, 1, 5, 4])

In [120]: s = pd.Series(data)

In [121]: s.value_counts()
Out[121]:
6    10
```

(continues on next page)

(continued from previous page)

```
2    10
4     9
3     8
5     8
0     3
1     2
dtype: int64

In [122]: pd.value_counts(data)
Out[122]:
6    10
2    10
4     9
3     8
5     8
0     3
1     2
dtype: int64
```

New in version 1.1.0.

The `value_counts()` method can be used to count combinations across multiple columns. By default all columns are used but a subset can be selected using the `subset` argument.

```
In [123]: data = {"a": [1, 2, 3, 4], "b": ["x", "x", "y", "y"]}
In [124]: frame = pd.DataFrame(data)

In [125]: frame.value_counts()
Out[125]:
a   b
1   x    1
2   x    1
3   y    1
4   y    1
dtype: int64
```

Similarly, you can get the most frequently occurring value(s), i.e. the mode, of the values in a Series or DataFrame:

```
In [126]: s5 = pd.Series([1, 1, 3, 3, 5, 5, 7, 7, 7])
In [127]: s5.mode()
Out[127]:
0    3
1    7
dtype: int64

In [128]: df5 = pd.DataFrame(
.....:     {
.....:         "A": np.random.randint(0, 7, size=50),
.....:         "B": np.random.randint(-10, 15, size=50),
.....:     }
.....: )
```

(continues on next page)

(continued from previous page)

```
....:

In [129]: df5.mode()
Out[129]:
   A    B
0  1.0 -9
1  NaN  10
2  NaN  13
```

Discretization and quantiling

Continuous values can be discretized using the `cut()` (bins based on values) and `qcut()` (bins based on sample quantiles) functions:

```
In [130]: arr = np.random.randn(20)

In [131]: factor = pd.cut(arr, 4)

In [132]: factor
Out[132]:
[(-0.251, 0.464], (-0.968, -0.251], (0.464, 1.179], (-0.251, 0.464], (-0.968, -0.251], ...
..., (-0.251, 0.464], (-0.968, -0.251], (-0.968, -0.251], (-0.968, -0.251], (-0.968, -0.
-251]]
Length: 20
Categories (4, interval[float64, right]): [(-0.968, -0.251] < (-0.251, 0.464] < (0.464, ...
1.179] <
                    (1.179, 1.893]]

In [133]: factor = pd.cut(arr, [-5, -1, 0, 1, 5])

In [134]: factor
Out[134]:
[(0, 1], (-1, 0], (0, 1], (0, 1], (-1, 0], ..., (-1, 0], (-1, 0], (-1, 0], (-1, 0], (-1, 0]
Length: 20
Categories (4, interval[int64, right]): [(-5, -1] < (-1, 0] < (0, 1] < (1, 5)]
```

`qcut()` computes sample quantiles. For example, we could slice up some normally distributed data into equal-size quartiles like so:

```
In [135]: arr = np.random.randn(30)

In [136]: factor = pd.qcut(arr, [0, 0.25, 0.5, 0.75, 1])

In [137]: factor
Out[137]:
[(0.569, 1.184], (-2.278, -0.301], (-2.278, -0.301], (0.569, 1.184], (0.569, 1.184], ...
..., (-0.301, 0.569], (1.184, 2.346], (1.184, 2.346], (-0.301, 0.569], (-2.278, -0.301])
Length: 30
Categories (4, interval[float64, right]): [(-2.278, -0.301] < (-0.301, 0.569] < (0.569, ...
1.184] <
```

(continues on next page)

(continued from previous page)

(1.184, 2.346])

In [138]: pd.value_counts(factor)**Out[138]:**

```
(-2.278, -0.301]      8  
(1.184, 2.346]       8  
(-0.301, 0.569]      7  
(0.569, 1.184]       7  
dtype: int64
```

We can also pass infinite values to define the bins:

In [139]: arr = np.random.randn(20)**In [140]:** factor = pd.cut(arr, [-np.inf, 0, np.inf])**In [141]:** factor**Out[141]:**

```
[(-inf, 0.0], (0.0, inf], (0.0, inf], (-inf, 0.0], (-inf, 0.0], ..., (-inf, 0.0], (-inf, 0.0],  
(-inf, 0.0], (-inf, 0.0], (0.0, inf], (0.0, inf])  
Length: 20  
Categories (2, interval[float64, right]): [(-inf, 0.0] < (0.0, inf]]
```

2.3.6 Function application

To apply your own or another library's functions to pandas objects, you should be aware of the three methods below. The appropriate method to use depends on whether your function expects to operate on an entire DataFrame or Series, row- or column-wise, or elementwise.

1. *Tablewise Function Application: pipe()*
2. *Row or Column-wise Function Application: apply()*
3. *Aggregation API: agg() and transform()*
4. *Applying Elementwise Functions: applymap()*

Tablewise function application

DataFrames and Series can be passed into functions. However, if the function needs to be called in a chain, consider using the `pipe()` method.

First some setup:

```
In [142]: def extract_city_name(df):  
.....:     """  
.....:     Chicago, IL -> Chicago for city_name column  
.....:  
.....:     df["city_name"] = df["city_and_code"].str.split(",")  
.....:     .str.get(0)  
.....:  
.....:
```

```
In [143]: def add_country_name(df, country_name=None):
```

(continues on next page)

(continued from previous page)

```

.....
Chicago -> Chicago-US for city_name column
.....
col = "city_name"
df["city_and_country"] = df[col] + country_name
return df
.....

```

In [144]: `df_p = pd.DataFrame({"city_and_code": ["Chicago, IL"]})`

`extract_city_name` and `add_country_name` are functions taking and returning DataFrames.

Now compare the following:

In [145]: `add_country_name(extract_city_name(df_p), country_name="US")`

Out[145]:

	city_and_code	city_name	city_and_country
0	Chicago, IL	Chicago	ChicagoUS

Is equivalent to:

In [146]: `df_p.pipe(extract_city_name).pipe(add_country_name, country_name="US")`

Out[146]:

	city_and_code	city_name	city_and_country
0	Chicago, IL	Chicago	ChicagoUS

pandas encourages the second style, which is known as method chaining. `pipe` makes it easy to use your own or another library's functions in method chains, alongside pandas' methods.

In the example above, the functions `extract_city_name` and `add_country_name` each expected a DataFrame as the first positional argument. What if the function you wish to apply takes its data as, say, the second argument? In this case, provide `pipe` with a tuple of (`callable`, `data_keyword`). `.pipe` will route the DataFrame to the argument specified in the tuple.

For example, we can fit a regression using statsmodels. Their API expects a formula first and a DataFrame as the second argument, `data`. We pass in the function, keyword pair (`sm.ols`, 'data') to pipe:

In [147]: `import statsmodels.formula.api as sm`

In [148]: `bb = pd.read_csv("data/baseball.csv", index_col="id")`

In [149]: (

```

.....
bb.query("h > 0")
.....
.assign(ln_h=lambda df: np.log(df.h))
.....
.pipe((sm.ols, "data"), "hr ~ ln_h + year + g + C(lg)")
.....
.fit()
.....
.summary()
.....
.....

```

Out[149]:

```
<class 'statsmodels.iolib.summary.Summary'>
.....
```

OLS Regression Results

<hr/>						

Notes:

- [1] Standard Errors assume that the covariance matrix of the errors **is** correctly specified.
- [2] The condition number **is** large, 1.49e+07. This might indicate that there are strong multicollinearity **or** other numerical problems.
-

The pipe method is inspired by unix pipes and more recently `dplyr` and `magrittr`, which have introduced the popular `(%>%)` (read pipe) operator for `R`. The implementation of pipe here is quite clean and feels right at home in Python. We encourage you to view the source code of `pipe()`.

Row or column-wise function application

Arbitrary functions can be applied along the axes of a DataFrame using the `apply()` method, which, like the descriptive statistics methods, takes an optional `axis` argument:

In [150]: `df.apply(np.mean)`**Out[150]:**

```
one      0.811094
two     1.360588
three    0.187958
dtype: float64
```

In [151]: `df.apply(np.mean, axis=1)`**Out[151]:**

```
a      1.583749
b      0.734929
```

(continues on next page)

(continued from previous page)

```
c    1.133683
d   -0.166914
dtype: float64

In [152]: df.apply(lambda x: x.max() - x.min())
Out[152]:
one      1.051928
two      1.632779
three     1.840607
dtype: float64

In [153]: df.apply(np.cumsum)
Out[153]:
   one      two      three
a  1.394981  1.772517      NaN
b  1.738035  3.684640 -0.050390
c  2.433281  5.163008  1.177045
d      NaN  5.442353  0.563873

In [154]: df.apply(np.exp)
Out[154]:
   one      two      three
a  4.034899  5.885648      NaN
b  1.409244  6.767440  0.950858
c  2.004201  4.385785  3.412466
d      NaN  1.322262  0.541630
```

The `apply()` method will also dispatch on a string method name.

```
In [155]: df.apply("mean")
Out[155]:
one      0.811094
two      1.360588
three     0.187958
dtype: float64

In [156]: df.apply("mean", axis=1)
Out[156]:
a      1.583749
b      0.734929
c      1.133683
d     -0.166914
dtype: float64
```

The return type of the function passed to `apply()` affects the type of the final output from `DataFrame.apply` for the default behaviour:

- If the applied function returns a `Series`, the final output is a `DataFrame`. The columns match the index of the `Series` returned by the applied function.
- If the applied function returns any other type, the final output is a `Series`.

This default behaviour can be overridden using the `result_type`, which accepts three options: `reduce`, `broadcast`, and `expand`. These will determine how list-likes return values expand (or not) to a `DataFrame`.

`apply()` combined with some cleverness can be used to answer many questions about a data set. For example, suppose we wanted to extract the date where the maximum value for each column occurred:

```
In [157]: tsdf = pd.DataFrame(
.....:     np.random.randn(1000, 3),
.....:     columns=["A", "B", "C"],
.....:     index=pd.date_range("1/1/2000", periods=1000),
.....: )
.....:

In [158]: tsdf.apply(lambda x: x.idxmax())
Out[158]:
A    2000-08-06
B    2001-01-18
C    2001-07-18
dtype: datetime64[ns]
```

You may also pass additional arguments and keyword arguments to the `apply()` method. For instance, consider the following function you would like to apply:

```
def subtract_and_divide(x, sub, divide=1):
    return (x - sub) / divide
```

You may then apply this function as follows:

```
df.apply(subtract_and_divide, args=(5,), divide=3)
```

Another useful feature is the ability to pass Series methods to carry out some Series operation on each column or row:

```
In [159]: tsdf
Out[159]:
          A         B         C
2000-01-01 -0.158131 -0.232466  0.321604
2000-01-02 -1.810340 -3.105758  0.433834
2000-01-03 -1.209847 -1.156793 -0.136794
2000-01-04      NaN      NaN      NaN
2000-01-05      NaN      NaN      NaN
2000-01-06      NaN      NaN      NaN
2000-01-07      NaN      NaN      NaN
2000-01-08 -0.653602  0.178875  1.008298
2000-01-09  1.007996  0.462824  0.254472
2000-01-10  0.307473  0.600337  1.643950
```

```
In [160]: tsdf.apply(pd.Series.interpolate)
Out[160]:
          A         B         C
2000-01-01 -0.158131 -0.232466  0.321604
2000-01-02 -1.810340 -3.105758  0.433834
2000-01-03 -1.209847 -1.156793 -0.136794
2000-01-04 -1.098598 -0.889659  0.092225
2000-01-05 -0.987349 -0.622526  0.321243
2000-01-06 -0.876100 -0.355392  0.550262
2000-01-07 -0.764851 -0.088259  0.779280
2000-01-08 -0.653602  0.178875  1.008298
```

(continues on next page)

(continued from previous page)

2000-01-09	1.007996	0.462824	0.254472
2000-01-10	0.307473	0.600337	1.643950

Finally, `apply()` takes an argument `raw` which is `False` by default, which converts each row or column into a Series before applying the function. When set to `True`, the passed function will instead receive an ndarray object, which has positive performance implications if you do not need the indexing functionality.

Aggregation API

The aggregation API allows one to express possibly multiple aggregation operations in a single concise way. This API is similar across pandas objects, see *groupby API*, the *window API*, and the *resample API*. The entry point for aggregation is `DataFrame.aggregate()`, or the alias `DataFrame.agg()`.

We will use a similar starting frame from above:

```
In [161]: tsdf = pd.DataFrame(
.....:     np.random.randn(10, 3),
.....:     columns=["A", "B", "C"],
.....:     index=pd.date_range("1/1/2000", periods=10),
.....: )
.....:

In [162]: tsdf.iloc[3:7] = np.nan

In [163]: tsdf
Out[163]:
          A           B           C
2000-01-01  1.257606  1.004194  0.167574
2000-01-02 -0.749892  0.288112 -0.757304
2000-01-03 -0.207550 -0.298599  0.116018
2000-01-04      NaN        NaN        NaN
2000-01-05      NaN        NaN        NaN
2000-01-06      NaN        NaN        NaN
2000-01-07      NaN        NaN        NaN
2000-01-08  0.814347 -0.257623  0.869226
2000-01-09 -0.250663 -1.206601  0.896839
2000-01-10  2.169758 -1.333363  0.283157
```

Using a single function is equivalent to `apply()`. You can also pass named methods as strings. These will return a Series of the aggregated output:

```
In [164]: tsdf.agg(np.sum)
```

```
Out[164]:
```

A	3.033606
B	-1.803879
C	1.575510
	dtype: float64

```
In [165]: tsdf.agg("sum")
```

```
Out[165]:
```

A	3.033606
B	-1.803879

(continues on next page)

(continued from previous page)

```
C    1.575510
dtype: float64

# these are equivalent to a ``.sum()`` because we are aggregating
# on a single function
In [166]: tsdf.sum()
Out[166]:
A    3.033606
B   -1.803879
C    1.575510
dtype: float64
```

Single aggregations on a Series this will return a scalar value:

```
In [167]: tsdf["A"].agg("sum")
Out[167]: 3.033606102414146
```

Aggregating with multiple functions

You can pass multiple aggregation arguments as a list. The results of each of the passed functions will be a row in the resulting DataFrame. These are naturally named from the aggregation function.

```
In [168]: tsdf.agg(["sum"])
Out[168]:
          A          B          C
sum  3.033606 -1.803879  1.57551
```

Multiple functions yield multiple rows:

```
In [169]: tsdf.agg(["sum", "mean"])
Out[169]:
          A          B          C
sum  3.033606 -1.803879  1.575510
mean  0.505601 -0.300647  0.262585
```

On a Series, multiple functions return a Series, indexed by the function names:

```
In [170]: tsdf["A"].agg(["sum", "mean"])
Out[170]:
sum    3.033606
mean   0.505601
Name: A, dtype: float64
```

Passing a lambda function will yield a <lambda> named row:

```
In [171]: tsdf["A"].agg(["sum", lambda x: x.mean()])
Out[171]:
sum    3.033606
<lambda>  0.505601
Name: A, dtype: float64
```

Passing a named function will yield that name for the row:

```
In [172]: def mymean(x):
.....:     return x.mean()
.....:

In [173]: tsdf["A"].agg(["sum", mymean])
Out[173]:
sum      3.033606
mymean   0.505601
Name: A, dtype: float64
```

Aggregating with a dict

Passing a dictionary of column names to a scalar or a list of scalars, to `DataFrame.agg` allows you to customize which functions are applied to which columns. Note that the results are not in any particular order, you can use an `OrderedDict` instead to guarantee ordering.

```
In [174]: tsdf.agg({"A": "mean", "B": "sum"})
Out[174]:
A    0.505601
B   -1.803879
dtype: float64
```

Passing a list-like will generate a `DataFrame` output. You will get a matrix-like output of all of the aggregators. The output will consist of all unique functions. Those that are not noted for a particular column will be `NaN`:

```
In [175]: tsdf.agg({"A": ["mean", "min"], "B": "sum"})
Out[175]:
          A          B
mean  0.505601      NaN
min  -0.749892      NaN
sum       NaN -1.803879
```

Mixed dtypes

Deprecated since version 1.4.0: Attempting to determine which columns cannot be aggregated and silently dropping them from the results is deprecated and will be removed in a future version. If any portion of the columns or operations provided fail, the call to `.agg` will raise.

When presented with mixed dtypes that cannot aggregate, `.agg` will only take the valid aggregations. This is similar to how `.groupby.agg` works.

```
In [176]: mdf = pd.DataFrame(
.....:     {
.....:         "A": [1, 2, 3],
.....:         "B": [1.0, 2.0, 3.0],
.....:         "C": ["foo", "bar", "baz"],
.....:         "D": pd.date_range("20130101", periods=3),
.....:     }
.....: )
```

(continues on next page)

(continued from previous page)

In [177]: mdf.dtypes**Out[177]:**

A	int64
B	float64
C	object
D	datetime64[ns]
dtype:	object

In [178]: mdf.agg(["min", "sum"])**Out[178]:**

	A	B	C	D
min	1	1.0	bar	2013-01-01
sum	6	6.0	foobarbaz	NaT

Custom describe

With .agg() it is possible to easily create a custom describe function, similar to the built in [describe function](#).

In [179]: `from functools import partial`**In [180]:** `q_25 = partial(pd.Series.quantile, q=0.25)`**In [181]:** `q_25.__name__ = "25%"`**In [182]:** `q_75 = partial(pd.Series.quantile, q=0.75)`**In [183]:** `q_75.__name__ = "75%"`**In [184]:** `tsdf.agg(["count", "mean", "std", "min", q_25, "median", q_75, "max"])`**Out[184]:**

	A	B	C
count	6.000000	6.000000	6.000000
mean	0.505601	-0.300647	0.262585
std	1.103362	0.887508	0.606860
min	-0.749892	-1.333363	-0.757304
25%	-0.239885	-0.979600	0.128907
median	0.303398	-0.278111	0.225365
75%	1.146791	0.151678	0.722709
max	2.169758	1.004194	0.896839

Transform API

The [transform\(\)](#) method returns an object that is indexed the same (same size) as the original. This API allows you to provide *multiple* operations at the same time rather than one-by-one. Its API is quite similar to the .agg API.

We create a frame similar to the one used in the above sections.

In [185]: `tsdf = pd.DataFrame(`
`.....: np.random.randn(10, 3),`
`.....: columns=["A", "B", "C"],`

(continues on next page)

(continued from previous page)

```
.....:     index=pd.date_range("1/1/2000", periods=10),
.....: )
.....:
```

In [186]: tsdf.iloc[3:7] = np.nan

In [187]: tsdf

Out[187]:

	A	B	C
2000-01-01	-0.428759	-0.864890	-0.675341
2000-01-02	-0.168731	1.338144	-1.279321

2000-01-09	0.157795	1.791197
2000-01-10	0.030876	1.371900

Applying elementwise functions

Since not all functions can be vectorized (accept NumPy arrays and return another array or value), the methods `applymap()` on DataFrame and analogously `map()` on Series accept any Python function taking a single value and returning a single value. For example:

```
In [197]: df4
```

Out[197]:

	one	two	three
a	1.394981	1.772517	NaN
b	0.343054	1.912123	-0.050390
c	0.695246	1.478369	1.227435
d	NaN	0.279344	-0.613172

```
In [198]: def f(x):
....:     return len(str(x))
....:
```

```
In [199]: df4["one"].map(f)
```

Out[199]:

a	18
b	19
c	18
d	3

Name: one, dtype: int64

```
In [200]: df4.applymap(f)
```

Out[200]:

	one	two	three
a	18	17	3
b	19	18	20

(continues on next page)

(continued from previous page)

c	18	18	16
d	3	19	19

`Series.map()` has an additional feature; it can be used to easily “link” or “map” values defined by a secondary series. This is closely related to *merging/joining functionality*:

```
In [201]: s = pd.Series(
.....:     ["six", "seven", "six", "seven", "six"], index=["a", "b", "c", "d", "e"]
.....: )
.....:

In [202]: t = pd.Series({"six": 6.0, "seven": 7.0})

In [203]: s
Out[203]:
a      six
b    seven
c      six
d    seven
e      six
dtype: object

In [204]: s.map(t)
Out[204]:
a    6.0
b    7.0
c    6.0
d    7.0
e    6.0
dtype: float64
```

2.3.7 Reindexing and altering labels

`reindex()` is the fundamental data alignment method in pandas. It is used to implement nearly all other features relying on label-alignment functionality. To *reindex* means to conform the data to match a given set of labels along a particular axis. This accomplishes several things:

- Reorders the existing data to match a new set of labels
- Inserts missing value (NA) markers in label locations where no data for that label existed
- If specified, `fill` data for missing labels using logic (highly relevant to working with time series data)

Here is a simple example:

```
In [205]: s = pd.Series(np.random.randn(5), index=["a", "b", "c", "d", "e"])

In [206]: s
Out[206]:
a    1.695148
b    1.328614
c    1.234686
d   -0.385845
```

(continues on next page)

(continued from previous page)

```
e    -1.326508
dtype: float64
```

In [207]: s.reindex(["e", "b", "f", "d"])

Out[207]:

```
e    -1.326508
b    1.328614
f      NaN
d   -0.385845
dtype: float64
```

Here, the f label was not contained in the Series and hence appears as NaN in the result.

With a DataFrame, you can simultaneously reindex the index and columns:

In [208]: df

Out[208]:

	one	two	three
a	1.394981	1.772517	NaN
b	0.343054	1.912123	-0.050390
c	0.695246	1.478369	1.227435
d	NaN	0.279344	-0.613172

In [209]: df.reindex(index=["c", "f", "b"], columns=["three", "two", "one"])

Out[209]:

	three	two	one
c	1.227435	1.478369	0.695246
f	NaN	NaN	NaN
b	-0.050390	1.912123	0.343054

You may also use `reindex` with an `axis` keyword:

In [210]: df.reindex(["c", "f", "b"], axis="index")

Out[210]:

	one	two	three
c	0.695246	1.478369	1.227435
f	NaN	NaN	NaN
b	0.343054	1.912123	-0.050390

Note that the Index objects containing the actual axis labels can be **shared** between objects. So if we have a Series and a DataFrame, the following can be done:

In [211]: rs = s.reindex(df.index)

In [212]: rs

Out[212]:

```
a    1.695148
b    1.328614
c    1.234686
d   -0.385845
dtype: float64
```

In [213]: rs.index **is** df.index

(continues on next page)

(continued from previous page)

Out[213]: True

This means that the reindexed Series's index is the same Python object as the DataFrame's index.

`DataFrame.reindex()` also supports an “axis-style” calling convention, where you specify a single `labels` argument and the `axis` it applies to.

In [214]: `df.reindex(["c", "f", "b"], axis="index")`**Out[214]:**

	one	two	three
c	0.695246	1.478369	1.227435
f	NaN	NaN	NaN
b	0.343054	1.912123	-0.050390

In [215]: `df.reindex(["three", "two", "one"], axis="columns")`**Out[215]:**

	three	two	one
a	NaN	1.772517	1.394981
b	-0.050390	1.912123	0.343054
c	1.227435	1.478369	0.695246
d	-0.613172	0.279344	NaN

See also:

[MultiIndex / Advanced Indexing](#) is an even more concise way of doing reindexing.

Note: When writing performance-sensitive code, there is a good reason to spend some time becoming a reindexing ninja: **many operations are faster on pre-aligned data**. Adding two unaligned DataFrames internally triggers a reindexing step. For exploratory analysis you will hardly notice the difference (because `reindex` has been heavily optimized), but when CPU cycles matter sprinkling a few explicit `reindex` calls here and there can have an impact.

Reindexing to align with another object

You may wish to take an object and reindex its axes to be labeled the same as another object. While the syntax for this is straightforward albeit verbose, it is a common enough operation that the `reindex_like()` method is available to make this simpler:

In [216]: `df2`**Out[216]:**

	one	two
a	1.394981	1.772517
b	0.343054	1.912123
c	0.695246	1.478369

In [217]: `df3`**Out[217]:**

	one	two
a	0.583888	0.051514
b	-0.468040	0.191120
c	-0.115848	-0.242634

(continues on next page)

(continued from previous page)

In [218]: df.reindex_like(df2)**Out[218]:**

```
one      two
a  1.394981  1.772517
b  0.343054  1.912123
c  0.695246  1.478369
```

Aligning objects with each other with align

The `align()` method is the fastest way to simultaneously align two objects. It supports a `join` argument (related to *joining and merging*):

- `join='outer'`: take the union of the indexes (default)
- `join='left'`: use the calling object's index
- `join='right'`: use the passed object's index
- `join='inner'`: intersect the indexes

It returns a tuple with both of the reindexed Series:

In [219]: s = pd.Series(np.random.randn(5), index=["a", "b", "c", "d", "e"])**In [220]:** s1 = s[:4]**In [221]:** s2 = s[1:]**In [222]:** s1.align(s2)**Out[222]:**

```
(a    -0.186646
 b    -1.692424
 c    -0.303893
 d    -1.425662
 e        NaN
dtype: float64,
a        NaN
b    -1.692424
c    -0.303893
d    -1.425662
e    1.114285
dtype: float64)
```

In [223]: s1.align(s2, join="inner")**Out[223]:**

```
(b    -1.692424
 c    -0.303893
 d    -1.425662
dtype: float64,
b    -1.692424
c    -0.303893
d    -1.425662
dtype: float64)
```

(continues on next page)

(continued from previous page)

```
In [224]: s1.align(s2, join="left")
Out[224]:
(a   -0.186646
 b   -1.692424
 c   -0.303893
 d   -1.425662
dtype: float64,
a      NaN
b   -1.692424
c   -0.303893
d   -1.425662
dtype: float64)
```

For DataFrames, the join method will be applied to both the index and the columns by default:

```
In [225]: df.align(df2, join="inner")
Out[225]:
(   one      two
 a  1.394981  1.772517
 b  0.343054  1.912123
 c  0.695246  1.478369,
   one      two
 a  1.394981  1.772517
 b  0.343054  1.912123
 c  0.695246  1.478369)
```

You can also pass an `axis` option to only align on the specified axis:

```
In [226]: df.align(df2, join="inner", axis=0)
Out[226]:
(   one      two      three
 a  1.394981  1.772517      NaN
 b  0.343054  1.912123 -0.050390
 c  0.695246  1.478369  1.227435,
   one      two
 a  1.394981  1.772517
 b  0.343054  1.912123
 c  0.695246  1.478369)
```

If you pass a Series to `DataFrame.align()`, you can choose to align both objects either on the DataFrame's index or columns using the `axis` argument:

```
In [227]: df.align(df2.iloc[0], axis=1)
Out[227]:
(   one      three      two
 a  1.394981      NaN  1.772517
 b  0.343054 -0.050390  1.912123
 c  0.695246  1.227435  1.478369
 d      NaN -0.613172  0.279344,
one      1.394981
three     NaN
```

(continues on next page)

(continued from previous page)

```
two      1.772517
Name: a, dtype: float64
```

Filling while reindexing

`reindex()` takes an optional parameter `method` which is a filling method chosen from the following table:

Method	Action
pad / ffill	Fill values forward
bfill / backfill	Fill values backward
nearest	Fill from the nearest index value

We illustrate these fill methods on a simple Series:

```
In [228]: rng = pd.date_range("1/3/2000", periods=8)
```

```
In [229]: ts = pd.Series(np.random.randn(8), index=rng)
```

```
In [230]: ts2 = ts[[0, 3, 6]]
```

```
In [231]: ts
```

```
Out[231]:
```

```

2000-01-09    0.733639
2000-01-10    0.733639
Freq: D, dtype: float64
```

These methods require that the indexes are **ordered** increasing or decreasing.

Note that the same result could have been achieved using `fillna` (except for `method='nearest'`) or `interpolate`:

```
In [237]: ts2.reindex(ts.index).fillna(method="ffill")
```

```
Out[237]:
```

```
2000-01-03    0.183051
2000-01-04    0.183051
2000-01-05    0.183051
2000-01-06    2.395489
2000-01-07    2.395489
2000-01-08    2.395489
2000-01-09    0.733639
2000-01-10    0.733639
Freq: D, dtype: float64
```

`reindex()` will raise a `ValueError` if the index is not monotonically increasing or decreasing. `fillna()` and `interpolate()` will not perform any checks on the order of the index.

Limits on filling while reindexing

The `limit` and `tolerance` arguments provide additional control over filling while reindexing. `Limit` specifies the maximum count of consecutive matches:

```
In [238]: ts2.reindex(ts.index, method="ffill", limit=1)
Out[238]:
2000-01-03    0.183051
2000-01-04    0.183051
2000-01-05      NaN
2000-01-06    2.395489
2000-01-07    2.395489
2000-01-08      NaN
2000-01-09    0.733639
2000-01-10    0.733639
Freq: D, dtype: float64
```

In contrast, `tolerance` specifies the maximum distance between the index and indexer values:

```
In [239]: ts2.reindex(ts.index, method="ffill", tolerance="1 day")
Out[239]:
2000-01-03    0.183051
2000-01-04    0.183051
2000-01-05      NaN
2000-01-06    2.395489
2000-01-07    2.395489
2000-01-08      NaN
2000-01-09    0.733639
2000-01-10    0.733639
Freq: D, dtype: float64
```

Notice that when used on a `DatetimeIndex`, `TimedeltaIndex` or `PeriodIndex`, `tolerance` will be coerced into a `Timedelta` if possible. This allows you to specify tolerance with appropriate strings.

Dropping labels from an axis

A method closely related to `reindex` is the `drop()` function. It removes a set of labels from an axis:

```
In [240]: df
Out[240]:
   one      two      three
a  1.394981  1.772517      NaN
b  0.343054  1.912123 -0.050390
c  0.695246  1.478369  1.227435
d      NaN  0.279344 -0.613172
```

```
In [241]: df.drop(["a", "d"], axis=0)
```

```
Out[241]:
   one      two      three
b  0.343054  1.912123 -0.050390
c  0.695246  1.478369  1.227435
```

(continues on next page)

(continued from previous page)

```
b  0.343054  1.912123 -0.050390
c  0.695246  1.478369  1.227435
```

In [242]: df.drop(["one"], axis=1)

Out[242]:

	two	three
a	1.772517	NaN
b	1.912123	-0.050390
c	1.478369	1.227435
d	0.279344	-0.613172

Note that the following also works, but is a bit less obvious / clean:

In [243]: df.reindex(df.index.difference(["a", "d"]))

Out[243]:

	one	two	three
b	0.343054	1.912123	-0.050390
c	0.695246	1.478369	1.227435

Renaming / mapping labels

The `rename()` method allows you to relabel an axis based on some mapping (a dict or Series) or an arbitrary function.

In [244]: s

Out[244]:

a	-0.186646
b	-1.692424
c	-0.303893
d	-1.425662
e	1.114285
	dtype: float64

In [245]: s.rename(str.upper)

Out[245]:

A	-0.186646
B	-1.692424
C	-0.303893
D	-1.425662
E	1.114285
	dtype: float64

If you pass a function, it must return a value when called with any of the labels (and must produce a set of unique values). A dict or Series can also be used:

In [246]: df.rename(
: columns={"one": "foo", "two": "bar"},
: index={"a": "apple", "b": "banana", "d": "durian"},
::
:)

Out[246]:

	foo	bar	three
--	-----	-----	-------

(continues on next page)

(continued from previous page)

apple	1.394981	1.772517	NaN
banana	0.343054	1.912123	-0.050390
c	0.695246	1.478369	1.227435
durian	NaN	0.279344	-0.613172

If the mapping doesn't include a column/index label, it isn't renamed. Note that extra labels in the mapping don't throw an error.

`DataFrame.rename()` also supports an “axis-style” calling convention, where you specify a single `mapper` and the `axis` to apply that mapping to.

```
In [247]: df.rename({"one": "foo", "two": "bar"}, axis="columns")
```

```
Out[247]:
```

	foo	bar	three
a	1.394981	1.772517	NaN
b	0.343054	1.912123	-0.050390
c	0.695246	1.478369	1.227435
d	NaN	0.279344	-0.613172

```
In [248]: df.rename({"a": "apple", "b": "banana", "d": "durian"}, axis="index")
```

```
Out[248]:
```

	one	two	three
apple	1.394981	1.772517	NaN
banana	0.343054	1.912123	-0.050390
c	0.695246	1.478369	1.227435
durian	NaN	0.279344	-0.613172

The `rename()` method also provides an `inplace` named parameter that is by default `False` and copies the underlying data. Pass `inplace=True` to rename the data in place.

Finally, `rename()` also accepts a scalar or list-like for altering the `Series.name` attribute.

```
In [249]: s.rename("scalar-name")
```

```
Out[249]:
```

a	-0.186646
b	-1.692424
c	-0.303893
d	-1.425662
e	1.114285

Name: scalar-name, dtype: float64

The methods `DataFrame.rename_axis()` and `Series.rename_axis()` allow specific names of a `MultiIndex` to be changed (as opposed to the labels).

```
In [250]: df = pd.DataFrame(
.....:     {"x": [1, 2, 3, 4, 5, 6], "y": [10, 20, 30, 40, 50, 60]},
.....:     index=pd.MultiIndex.from_product(
.....:         [["a", "b", "c"], [1, 2]], names=["let", "num"])
.....:     ),
.....: )
.....:
```

```
In [251]: df
```

```
Out[251]:
```

(continues on next page)

(continued from previous page)

```

        x   y
let num
a   1   10
    2   20
b   1   30
    2   40
c   1   50
    2   60

```

In [252]: df.rename_axis(index={"let": "abc"})

Out[252]:

```

        x   y
abc num
a   1   10
    2   20
b   1   30
    2   40
c   1   50
    2   60

```

In [253]: df.rename_axis(index=str.upper)

Out[253]:

```

        x   y
LET NUM
a   1   10
    2   20
b   1   30
    2   40
c   1   50
    2   60

```

2.3.8 Iteration

The behavior of basic iteration over pandas objects depends on the type. When iterating over a Series, it is regarded as array-like, and basic iteration produces the values. DataFrames follow the dict-like convention of iterating over the “keys” of the objects.

In short, basic iteration (`for i in object`) produces:

- **Series:** values
- **DataFrame:** column labels

Thus, for example, iterating over a DataFrame gives you the column names:

```

In [254]: df = pd.DataFrame(
.....:     {"col1": np.random.randn(3), "col2": np.random.randn(3)}, index=["a", "b",
→"c"]
.....: )
.....:

In [255]: for col in df:
.....:     print(col)

```

(continues on next page)

(continued from previous page)

```
.....:  
col1  
col2
```

pandas objects also have the dict-like `items()` method to iterate over the (key, value) pairs.

To iterate over the rows of a DataFrame, you can use the following methods:

- `iterrows()`: Iterate over the rows of a DataFrame as (index, Series) pairs. This converts the rows to Series objects, which can change the dtypes and has some performance implications.
- `itertuples()`: Iterate over the rows of a DataFrame as namedtuples of the values. This is a lot faster than `iterrows()`, and is in most cases preferable to use to iterate over the values of a DataFrame.

Warning: Iterating through pandas objects is generally **slow**. In many cases, iterating manually over the rows is not needed and can be avoided with one of the following approaches:

- Look for a *vectorized* solution: many operations can be performed using built-in methods or NumPy functions, (boolean) indexing, ...
- When you have a function that cannot work on the full DataFrame/Series at once, it is better to use `apply()` instead of iterating over the values. See the docs on [function application](#).
- If you need to do iterative manipulations on the values but performance is important, consider writing the inner loop with cython or numba. See the [enhancing performance](#) section for some examples of this approach.

Warning: You should **never modify** something you are iterating over. This is not guaranteed to work in all cases. Depending on the data types, the iterator returns a copy and not a view, and writing to it will have no effect!

For example, in the following case setting the value has no effect:

```
In [256]: df = pd.DataFrame({"a": [1, 2, 3], "b": ["a", "b", "c"]})  
  
In [257]: for index, row in df.iterrows():  
.....:     row["a"] = 10  
.....:  
  
In [258]: df  
Out[258]:  
   a  b  
0  1  a  
1  2  b  
2  3  c
```

items

Consistent with the dict-like interface, `items()` iterates through key-value pairs:

- **Series**: (index, scalar value) pairs
- **DataFrame**: (column, Series) pairs

For example:

```
In [259]: for label, ser in df.items():
    ....:     print(label)
    ....:     print(ser)
    ....:

a
0    1
1    2
2    3
Name: a, dtype: int64
b
0    a
1    b
2    c
Name: b, dtype: object
```

iterrows

`iterrows()` allows you to iterate through the rows of a DataFrame as Series objects. It returns an iterator yielding each index value along with a Series containing the data in each row:

```
In [260]: for row_index, row in df.iterrows():
    ....:     print(row_index, row, sep="\n")
    ....:

0
a    1
b    a
Name: 0, dtype: object
1
a    2
b    b
Name: 1, dtype: object
2
a    3
b    c
Name: 2, dtype: object
```

Note: Because `iterrows()` returns a Series for each row, it does **not** preserve dtypes across the rows (dtypes are preserved across columns for DataFrames). For example,

```
In [261]: df_orig = pd.DataFrame([[1, 1.5]], columns=["int", "float"])
```

```
In [262]: df_orig.dtypes
Out[262]:
```

(continues on next page)

(continued from previous page)

```
int      int64
float    float64
dtype: object

In [263]: row = next(df_orig.iterrows())[1]

In [264]: row
Out[264]:
int      1.0
float    1.5
Name: 0, dtype: float64
```

All values in `row`, returned as a Series, are now upcasted to floats, also the original integer value in column `x`:

```
In [265]: row["int"].dtype
Out[265]: dtype('float64')

In [266]: df_orig["int"].dtype
Out[266]: dtype('int64')
```

To preserve dtypes while iterating over the rows, it is better to use `iterntuples()` which returns namedtuples of the values and which is generally much faster than `iterrows()`.

For instance, a contrived way to transpose the DataFrame would be:

```
In [267]: df2 = pd.DataFrame({"x": [1, 2, 3], "y": [4, 5, 6]})

In [268]: print(df2)
   x  y
0  1  4
1  2  5
2  3  6

In [269]: print(df2.T)
   0  1  2
x  1  2  3
y  4  5  6

In [270]: df2_t = pd.DataFrame({idx: values for idx, values in df2.iterrows()})

In [271]: print(df2_t)
   0  1  2
x  1  2  3
y  4  5  6
```

itertuples

The `itertuples()` method will return an iterator yielding a namedtuple for each row in the DataFrame. The first element of the tuple will be the row's corresponding index value, while the remaining values are the row values.

For instance:

```
In [272]: for row in df.itertuples():
    ....:     print(row)
    ....:
Pandas(Index=0, a=1, b='a')
Pandas(Index=1, a=2, b='b')
Pandas(Index=2, a=3, b='c')
```

This method does not convert the row to a Series object; it merely returns the values inside a namedtuple. Therefore, `itertuples()` preserves the data type of the values and is generally faster as `iterrows()`.

Note: The column names will be renamed to positional names if they are invalid Python identifiers, repeated, or start with an underscore. With a large number of columns (>255), regular tuples are returned.

2.3.9 .dt accessor

Series has an accessor to succinctly return datetime like properties for the *values* of the Series, if it is a datetime/period like Series. This will return a Series, indexed like the existing Series.

```
# datetime
In [273]: s = pd.Series(pd.date_range("20130101 09:10:12", periods=4))

In [274]: s
Out[274]:
0    2013-01-01 09:10:12
1    2013-01-02 09:10:12
2    2013-01-03 09:10:12
3    2013-01-04 09:10:12
dtype: datetime64[ns]

In [275]: s.dt.hour
Out[275]:
0    9
1    9
2    9
3    9
dtype: int64

In [276]: s.dt.second
Out[276]:
0    12
1    12
2    12
3    12
dtype: int64
```

(continues on next page)

(continued from previous page)

In [277]: s.dt.day**Out[277]:**

```
0    1  
1    2  
2    3  
3    4  
dtype: int64
```

This enables nice expressions like this:

In [278]: s[s.dt.day == 2]**Out[278]:**

```
1    2013-01-02 09:10:12  
dtype: datetime64[ns]
```

You can easily produce tz aware transformations:

In [279]: stz = s.dt.tz_localize("US/Eastern")**In [280]:** stz**Out[280]:**

```
0    2013-01-01 09:10:12-05:00  
1    2013-01-02 09:10:12-05:00  
2    2013-01-03 09:10:12-05:00  
3    2013-01-04 09:10:12-05:00  
dtype: datetime64[ns, US/Eastern]
```

In [281]: stz.dt.tz**Out[281]:** <DstTzInfo 'US/Eastern' LMT-1 day, 19:04:00 STD>

You can also chain these types of operations:

In [282]: s.dt.tz_localize("UTC").dt.tz_convert("US/Eastern")**Out[282]:**

```
0    2013-01-01 04:10:12-05:00  
1    2013-01-02 04:10:12-05:00  
2    2013-01-03 04:10:12-05:00  
3    2013-01-04 04:10:12-05:00  
dtype: datetime64[ns, US/Eastern]
```

You can also format datetime values as strings with `Series.dt.strftime()` which supports the same format as the standard `strftime()`.

```
# DatetimeIndex
```

In [283]: s = pd.Series(pd.date_range("20130101", periods=4))**In [284]:** s**Out[284]:**

```
0    2013-01-01  
1    2013-01-02  
2    2013-01-03  
3    2013-01-04  
dtype: datetime64[ns]
```

(continues on next page)

(continued from previous page)

In [285]: s.dt.strftime("%Y/%m/%d")**Out[285]:**

```
0    2013/01/01
1    2013/01/02
2    2013/01/03
3    2013/01/04
dtype: object
```

PeriodIndex

In [286]: s = pd.Series(pd.period_range("20130101", periods=4))**In [287]:** s**Out[287]:**

```
0    2013-01-01
1    2013-01-02
2    2013-01-03
3    2013-01-04
dtype: period[D]
```

In [288]: s.dt.strftime("%Y/%m/%d")**Out[288]:**

```
0    2013/01/01
1    2013/01/02
2    2013/01/03
3    2013/01/04
dtype: object
```

The .dt accessor works for period and timedelta dtypes.

period

In [289]: s = pd.Series(pd.period_range("20130101", periods=4, freq="D"))**In [290]:** s**Out[290]:**

```

0     1      0        0       5            0            0            0
1     1      0        0       6            0            0            0
2     1      0        0       7            0            0            0
3     1      0        0       8            0            0            0
```

Note: Series.dt will raise a TypeError if you access with a non-datetime-like values.

2.3.10 Vectorized string methods

Series is equipped with a set of string processing methods that make it easy to operate on each element of the array. Perhaps most importantly, these methods exclude missing/NA values automatically. These are accessed via the Series's `str` attribute and generally have names matching the equivalent (scalar) built-in string methods. For example:

```
In [298]: s = pd.Series([
    ....:     ["A", "B", "C", "Aaba", "Baca", np.nan, "CABA", "dog", "cat"],
    ....:     dtype="string"
    ....: )
    ....:

In [299]: s.str.lower()
Out[299]:
0      a
1      b
2      c
3     aaba
4     baca
5    <NA>
6     caba
7     dog
8     cat
dtype: string
```

Powerful pattern-matching methods are provided as well, but note that pattern-matching generally uses [regular expressions](#) by default (and in some cases always uses them).

Note: Prior to pandas 1.0, string methods were only available on `object`-dtype `Series`. pandas 1.0 added the `StringDtype` which is dedicated to strings. See [Text data types](#) for more.

Please see [Vectorized String Methods](#) for a complete description.

2.3.11 Sorting

pandas supports three kinds of sorting: sorting by index labels, sorting by column values, and sorting by a combination of both.

By index

The `Series.sort_index()` and `DataFrame.sort_index()` methods are used to sort a pandas object by its index levels.

```
In [300]: df = pd.DataFrame(
    ....:     {
    ....:         "one": pd.Series(np.random.randn(3), index=["a", "b", "c"]),
    ....:         "two": pd.Series(np.random.randn(4), index=["a", "b", "c", "d"]),
    ....:         "three": pd.Series(np.random.randn(3), index=["b", "c", "d"]),
    ....:     }
    ....: )
```

(continues on next page)

(continued from previous page)

```
In [301]: unsorted_df = df.reindex(  
.....:     index=["a", "d", "c", "b"], columns=["three", "two", "one"]  
.....: )  
.....:  
  
In [302]: unsorted_df  
Out[302]:  
      three      two      one  
a      NaN -1.152244  0.562973  
d -0.252916 -0.109597      NaN  
c  1.273388 -0.167123  0.640382  
b -0.098217  0.009797 -1.299504  
  
# DataFrame  
In [303]: unsorted_df.sort_index()  
Out[303]:  
      three      two      one  
a      NaN -1.152244  0.562973  
b -0.098217  0.009797 -1.299504  
c  1.273388 -0.167123  0.640382  
d -0.252916 -0.109597      NaN  
  
In [304]: unsorted_df.sort_index(ascending=False)  
Out[304]:  
      three      two      one  
d -0.252916 -0.109597      NaN  
c  1.273388 -0.167123  0.640382  
b -0.098217  0.009797 -1.299504  
a      NaN -1.152244  0.562973  
  
In [305]: unsorted_df.sort_index(axis=1)  
Out[305]:  
      one      three      two  
a  0.562973      NaN -1.152244  
d      NaN -0.252916 -0.109597  
c  0.640382  1.273388 -0.167123  
b -1.299504 -0.098217  0.009797  
  
# Series  
In [306]: unsorted_df["three"].sort_index()  
Out[306]:  
a      NaN  
b -0.098217  
c  1.273388  
d -0.252916  
Name: three, dtype: float64
```

New in version 1.1.0.

Sorting by index also supports a `key` parameter that takes a callable function to apply to the index being sorted. For `MultiIndex` objects, the `key` is applied per-level to the levels specified by `level`.

```
In [307]: s1 = pd.DataFrame({"a": ["B", "a", "C"], "b": [1, 2, 3], "c": [2, 3, 4]}).set_
           index(
               ....:     list("ab")
               ....: )
               ....:

In [308]: s1
Out[308]:
      c
a b
B 1 2
a 2 3
C 3 4
```

```
In [309]: s1.sort_index(level="a")
Out[309]:
      c
a b
B 1 2
C 3 4
a 2 3

In [310]: s1.sort_index(level="a", key=lambda idx: idx.str.lower())
Out[310]:
      c
a b
a 2 3
B 1 2
C 3 4
```

For information on key sorting by value, see [value sorting](#).

By values

The `Series.sort_values()` method is used to sort a Series by its values. The `DataFrame.sort_values()` method is used to sort a DataFrame by its column or row values. The optional `by` parameter to `DataFrame.sort_values()` may be used to specify one or more columns to use to determine the sorted order.

```
In [311]: df1 = pd.DataFrame(
           ....:     {"one": [2, 1, 1, 1], "two": [1, 3, 2, 4], "three": [5, 4, 3, 2]}
           ....: )
           ....:

In [312]: df1.sort_values(by="two")
Out[312]:
   one  two  three
0    2    1     5
2    1    2     3
1    1    3     4
3    1    4     2
```

The `by` parameter can take a list of column names, e.g.:

```
In [313]: df1[["one", "two", "three"]].sort_values(by=["one", "two"])
Out[313]:
   one  two  three
2    1    2     3
1    1    3     4
3    1    4     2
0    2    1     5
```

These methods have special treatment of NA values via the `na_position` argument:

```
In [314]: s[2] = np.nan
In [315]: s.sort_values()
Out[315]:
0      A
3    Aaba
1      B
4    Baca
6   CABA
8    cat
7   dog
2  <NA>
5  <NA>
dtype: string

In [316]: s.sort_values(na_position="first")
Out[316]:
2  <NA>
5  <NA>
0      A
3    Aaba
1      B
4    Baca
6   CABA
8    cat
7   dog
dtype: string
```

New in version 1.1.0.

Sorting also supports a `key` parameter that takes a callable function to apply to the values being sorted.

```
In [317]: s1 = pd.Series(["B", "a", "C"])
```

```
In [318]: s1.sort_values()
Out[318]:
0    B
2    C
1    a
dtype: object

In [319]: s1.sort_values(key=lambda x: x.str.lower())
Out[319]:
```

(continues on next page)

(continued from previous page)

```
1    a
0    B
2    C
dtype: object
```

key will be given the `Series` of values and should return a `Series` or array of the same shape with the transformed values. For `DataFrame` objects, the key is applied per column, so the key should still expect a `Series` and return a `Series`, e.g.

```
In [320]: df = pd.DataFrame({"a": ["B", "a", "C"], "b": [1, 2, 3]})
```

```
In [321]: df.sort_values(by="a")
```

```
Out[321]:
```

```
a   b
0   B   1
2   C   3
1   a   2
```

```
In [322]: df.sort_values(by="a", key=lambda col: col.str.lower())
```

```
Out[322]:
```

```
a   b
1   a   2
0   B   1
2   C   3
```

The name or type of each column can be used to apply different functions to different columns.

By indexes and values

Strings passed as the by parameter to `DataFrame.sort_values()` may refer to either columns or index level names.

```
# Build MultiIndex
```

```
In [323]: idx = pd.MultiIndex.from_tuples(
.....:     [("a", 1), ("a", 2), ("a", 2), ("b", 2), ("b", 1), ("b", 1)]
.....: )
.....:
```

```
In [324]: idx.names = ["first", "second"]
```

```
# Build DataFrame
```

```
In [325]: df_multi = pd.DataFrame({"A": np.arange(6, 0, -1)}, index=idx)
```

```
In [326]: df_multi
```

```
Out[326]:
```

		A
first	second	
a	1	6
	2	5
	2	4
b	2	3
	1	2
	1	1

Sort by ‘second’ (index) and ‘A’ (column)

```
In [327]: df_multi.sort_values(by=["second", "A"])
Out[327]:
      A
first second
b      1      1
       1      2
a      1      6
b      2      3
a      2      4
       2      5
```

Note: If a string matches both a column name and an index level name then a warning is issued and the column takes precedence. This will result in an ambiguity error in a future version.

searchsorted

Series has the `searchsorted()` method, which works similarly to `numpy.ndarray.searchsorted()`.

```
In [328]: ser = pd.Series([1, 2, 3])

In [329]: ser.searchsorted([0, 3])
Out[329]: array([0, 2])

In [330]: ser.searchsorted([0, 4])
Out[330]: array([0, 3])

In [331]: ser.searchsorted([1, 3], side="right")
Out[331]: array([1, 3])

In [332]: ser.searchsorted([1, 3], side="left")
Out[332]: array([0, 2])

In [333]: ser = pd.Series([3, 1, 2])

In [334]: ser.searchsorted([0, 3], sorter=np.argsort(ser))
Out[334]: array([0, 2])
```

smallest / largest values

Series has the `nsmallest()` and `nlargest()` methods which return the smallest or largest n values. For a large Series this can be much faster than sorting the entire Series and calling `head(n)` on the result.

```
In [335]: s = pd.Series(np.random.permutation(10))

In [336]: s
Out[336]:
0    2
1    0
```

(continues on next page)

(continued from previous page)

```
2    3
3    7
4    1
5    5
6    9
7    6
8    8
9    4
dtype: int64
```

In [337]: s.sort_values()

Out[337]:

```
1    0
4    1
0    2
2    3
9    4
5    5
7    6
3    7
8    8
6    9
dtype: int64
```

In [338]: s.nsmallest(3)

Out[338]:

```
1    0
4    1
0    2
dtype: int64
```

In [339]: s.nlargest(3)

Out[339]:

```
6    9
8    8
3    7
dtype: int64
```

DataFrame also has the nlargest and nsmallest methods.

```
In [340]: df = pd.DataFrame(
.....:     {
.....:         "a": [-2, -1, 1, 10, 8, 11, -1],
.....:         "b": list("abdceff"),
.....:         "c": [1.0, 2.0, 4.0, 3.2, np.nan, 3.0, 4.0],
.....:     }
.....: )
.....:
```

In [341]: df.nlargest(3, "a")

Out[341]:

```
a  b      c
```

(continues on next page)

(continued from previous page)

```
5  11  f  3.0
3  10  c  3.2
4   8  e  NaN
```

In [342]: df.nlargest(5, ["a", "c"])

Out[342]:

```
      a    b    c
5  11  f  3.0
3  10  c  3.2
4   8  e  NaN
2   1  d  4.0
6  -1  f  4.0
```

In [343]: df.nsmallest(3, "a")

Out[343]:

```
      a    b    c
0  -2  a  1.0
1  -1  b  2.0
6  -1  f  4.0
```

In [344]: df.nsmallest(5, ["a", "c"])

Out[344]:

```
      a    b    c
0  -2  a  1.0
1  -1  b  2.0
6  -1  f  4.0
2   1  d  4.0
4   8  e  NaN
```

Sorting by a MultiIndex column

You must be explicit about sorting when the column is a MultiIndex, and fully specify all levels to by.

In [345]: df1.columns = pd.MultiIndex.from_tuples([
.....: [("a", "one"), ("a", "two"), ("b", "three")]
.....:)
.....:

In [346]: df1.sort_values(by=("a", "two"))

Out[346]:

	a	b	
	one	two	three
0	2	1	5
2	1	2	3
1	1	3	4
3	1	4	2

2.3.12 Copying

The `copy()` method on pandas objects copies the underlying data (though not the axis indexes, since they are immutable) and returns a new object. Note that **it is seldom necessary to copy objects**. For example, there are only a handful of ways to alter a DataFrame *in-place*:

- Inserting, deleting, or modifying a column.
- Assigning to the `index` or `columns` attributes.
- For homogeneous data, directly modifying the values via the `values` attribute or advanced indexing.

To be clear, no pandas method has the side effect of modifying your data; almost every method returns a new object, leaving the original object untouched. If the data is modified, it is because you did so explicitly.

2.3.13 dtypes

For the most part, pandas uses NumPy arrays and dtypes for Series or individual columns of a DataFrame. NumPy provides support for `float`, `int`, `bool`, `timedelta64[ns]` and `datetime64[ns]` (note that NumPy does not support timezone-aware datetimes).

pandas and third-party libraries *extend* NumPy's type system in a few places. This section describes the extensions pandas has made internally. See [Extension types](#) for how to write your own extension that works with pandas. See `ecosystem.extensions` for a list of third-party libraries that have implemented an extension.

The following table lists all of pandas extension types. For methods requiring `dtype` arguments, strings can be specified as indicated. See the respective documentation sections for more on each type.

Kind of Data	Data Type	Scalar	Array	String Aliases
<code>tz-aware date-time</code>	<code>DatetimeTZDtype</code>	<code>Timestamp</code>	<code>arrays.DatetimeArray</code>	' <code>datetime64[ns, <tz>]</code> '
<code>Categorical</code>	<code>CategoricalDtype</code>	<code>None</code>	<code>Categorical</code>	' <code>category</code> '
<code>period (time spans)</code>	<code>PeriodDtype</code>	<code>Period</code>	<code>arrays.PeriodArray</code> ' <code>Period[<freq>]</code> '	' <code>period[<freq>]</code> ', ' <code>Period[<freq>]</code> '
<code>sparse</code>	<code>SparseDtype</code>	(<code>none</code>)	<code>arrays.SparseArray</code>	' <code>Sparse</code> ', ' <code>Sparse[int]</code> ', ' <code>Sparse[float]</code> '
<code>intervals</code>	<code>IntervalDtype</code>	<code>Interval</code>	<code>arrays.IntervalArray</code>	' <code>interval</code> ', ' <code>Interval</code> ', ' <code>Interval[<numpy_dtype>]</code> ', ' <code>Interval[datetime64[ns, <tz>]]</code> ', ' <code>Interval[timedelta64[<freq>]]</code> '
<code>nullable integer</code>	<code>Int64Dtype</code>	(<code>none</code>) ...	<code>arrays.IntegerArray</code>	' <code>Int8</code> ', ' <code>Int16</code> ', ' <code>Int32</code> ', ' <code>Int64</code> ', ' <code>UInt8</code> ', ' <code>UInt16</code> ', ' <code>UInt32</code> ', ' <code>UInt64</code> '
<code>Strings</code>	<code>StringDtype</code>	<code>str</code>	<code>arrays.StringArray</code>	' <code>string</code> '
<code>Boolean (with NA)</code>	<code>BooleanDtype</code>	<code>bool</code>	<code>arrays.BooleanArray</code>	' <code>boolean</code> '

pandas has two ways to store strings.

1. `object` dtype, which can hold any Python object, including strings.
 2. `StringDtype`, which is dedicated to strings.

Generally, we recommend using `StringDtype`. See *Text data types* for more.

Finally, arbitrary objects may be stored using the `object` dtype, but should be avoided to the extent possible (for performance and interoperability with other libraries and methods. See [object conversion](#)).

A convenient `dtypes` attribute for DataFrame returns a Series with the data type of each column.

```
In [347]: dft = pd.DataFrame(  
.....:     {  
.....:         "A": np.random.rand(3),  
.....:         "B": 1,  
.....:         "C": "foo",  
.....:         "D": pd.Timestamp("20010102"),  
.....:         "E": pd.Series([1.0] * 3).astype("float32"),  
.....:         "F": False,  
.....:         "G": pd.Series([1] * 3, dtype="int8"),  
.....:     }  
.....: )
```

```
In [348]: dft
Out[348]:
```

	A	B	C	D	E	F	G
0	0.035962	1	foo	2001-01-02	1.0	False	1
1	0.701379	1	foo	2001-01-02	1.0	False	1
2	0.281885	1	foo	2001-01-02	1.0	False	1

```
In [349]: dft.dtypes
Out[349]:
A           float64
B           int64
C          object
D  datetime64[ns]
E          float32
F           bool
G          int8
dtype: object
```

On a Series object, use the `dtype` attribute.

```
In [350]: dft["A"].dtype  
Out[350]: dtype('float64')
```

If a pandas object contains data with multiple dtypes *in a single column*, the dtype of the column will be chosen to accommodate all of the data types (`object` is the most general).

```
# these ints are coerced to floats
In [351]: pd.Series([1, 2, 3, 4, 5, 6.0])
Out[351]:
0    1.0
```

(continues on next page)

(continued from previous page)

```

1    2.0
2    3.0
3    4.0
4    5.0
5    6.0
dtype: float64

# string data forces an ``object`` dtype
In [352]: pd.Series([1, 2, 3, 6.0, "foo"])
Out[352]:
0      1
1      2
2      3
3    6.0
4    foo
dtype: object

```

The number of columns of each type in a DataFrame can be found by calling `DataFrame.dtypes.value_counts()`.

```

In [353]: dft.dtypes.value_counts()
Out[353]:
float64      1
int64        1
object       1
datetime64[ns] 1
float32      1
bool         1
int8         1
dtype: int64

```

Numeric dtypes will propagate and can coexist in DataFrames. If a dtype is passed (either directly via the `dtype` keyword, a passed `ndarray`, or a passed `Series`), then it will be preserved in DataFrame operations. Furthermore, different numeric dtypes will **NOT** be combined. The following example will give you a taste.

```

In [354]: df1 = pd.DataFrame(np.random.randn(8, 1), columns=["A"], dtype="float32")

In [355]: df1
Out[355]:
          A
0  0.224364
1  1.890546
2  0.182879
3  0.787847
4 -0.188449
5  0.667715
6 -0.011736
7 -0.399073

In [356]: df1.dtypes
Out[356]:
A    float32
dtype: object

```

(continues on next page)

(continued from previous page)

```
In [357]: df2 = pd.DataFrame(  
.....:     {  
.....:         "A": pd.Series(np.random.randn(8), dtype="float16"),  
.....:         "B": pd.Series(np.random.randn(8)),  
.....:         "C": pd.Series(np.array(np.random.randn(8)), dtype="uint8")),  
.....:     }  
.....:  
.....:  
In [358]: df2  
Out[358]:  
          A           B   C  
0  0.823242  0.256090   0  
1  1.607422  1.426469   0  
2 -0.333740 -0.416203  255  
3 -0.063477  1.139976   0  
4 -1.014648 -1.193477   0  
5  0.678711  0.096706   0  
6 -0.040863 -1.956850   1  
7 -0.357422 -0.714337   0  
  
In [359]: df2.dtypes  
Out[359]:  
A    float16  
B    float64  
C    uint8  
dtype: object
```

defaults

By default integer types are `int64` and float types are `float64`, *regardless* of platform (32-bit or 64-bit). The following will all result in `int64` dtypes.

```
In [360]: pd.DataFrame([1, 2], columns=["a"]).dtypes  
Out[360]:  
a    int64  
dtype: object  
  
In [361]: pd.DataFrame({"a": [1, 2]}).dtypes  
Out[361]:  
a    int64  
dtype: object  
  
In [362]: pd.DataFrame({"a": 1}, index=list(range(2))).dtypes  
Out[362]:  
a    int64  
dtype: object
```

Note that Numpy will choose *platform-dependent* types when creating arrays. The following **WILL** result in `int32` on 32-bit platform.

```
In [363]: frame = pd.DataFrame(np.array([1, 2]))
```

upcasting

Types can potentially be *upcasted* when combined with other types, meaning they are promoted from the current type (e.g. int to float).

```
In [364]: df3 = df1.reindex_like(df2).fillna(value=0.0) + df2
```

```
In [365]: df3
```

```
Out[365]:
```

	A	B	C
0	1.047606	0.256090	0.0
1	3.497968	1.426469	0.0
2	-0.150862	-0.416203	255.0
3	0.724370	1.139976	0.0
4	-1.203098	-1.193477	0.0
5	1.346426	0.096706	0.0
6	-0.052599	-1.956850	1.0
7	-0.756495	-0.714337	0.0

```
In [366]: df3.dtypes
```

```
Out[366]:
```

A	float32
B	float64
C	float64
dtype:	object

`DataFrame.to_numpy()` will return the *lower-common-denominator* of the dtypes, meaning the dtype that can accommodate **ALL** of the types in the resulting homogeneous dtypes NumPy array. This can force some *upcasting*.

```
In [367]: df3.to_numpy().dtype
```

```
Out[367]: dtype('float64')
```

astype

You can use the `astype()` method to explicitly convert dtypes from one to another. These will by default return a copy, even if the dtype was unchanged (pass `copy=False` to change this behavior). In addition, they will raise an exception if the astype operation is invalid.

Upcasting is always according to the **NumPy** rules. If two different dtypes are involved in an operation, then the more *general* one will be used as the result of the operation.

```
In [368]: df3
```

```
Out[368]:
```

	A	B	C
0	1.047606	0.256090	0.0
1	3.497968	1.426469	0.0
2	-0.150862	-0.416203	255.0
3	0.724370	1.139976	0.0
4	-1.203098	-1.193477	0.0

(continues on next page)

(continued from previous page)

6 -0.052599 -1.956850    1.0
7 -0.756495 -0.714337    0.0
```

In [369]: df3.dtypes**Out[369]:**

```
A      float32
B      float64
C      float64
dtype: object
```

conversion of dtypes

In [370]: df3.astype("float32").dtypes**Out[370]:**

```
A      float32
B      float32
C      float32
dtype: object
```

Convert a subset of columns to a specified type using `astype()`.**In [371]:** dft = pd.DataFrame({"a": [1, 2, 3], "b": [4, 5, 6], "c": [7, 8, 9]})**In [372]:** dft[["a", "b"]] = dft[["a", "b"]].astype(np.uint8)**In [373]:** dft**Out[373]:**

	a	b	c
0	1	4	7
1	2	5	8
2	3	6	9

In [374]: dft.dtypes**Out[374]:**

```
a      uint8
b      uint8
c      int64
dtype: object
```

Convert certain columns to a specific dtype by passing a dict to `astype()`.**In [375]:** dft1 = pd.DataFrame({"a": [1, 0, 1], "b": [4, 5, 6], "c": [7, 8, 9]})**In [376]:** dft1 = dft1.astype({"a": np.bool_, "c": np.float64})**In [377]:** dft1**Out[377]:**

	a	b	c
0	True	4	7.0
1	False	5	8.0
2	True	6	9.0

(continues on next page)

(continued from previous page)

In [378]: dft1.dtypes**Out[378]:**

```
a      bool
b     int64
c    float64
dtype: object
```

Note: When trying to convert a subset of columns to a specified type using `astype()` and `loc()`, upcasting occurs.

`loc()` tries to fit in what we are assigning to the current dtypes, while `[]` will overwrite them taking the dtype from the right hand side. Therefore the following piece of code produces the unintended result.

In [379]: dft = pd.DataFrame({"a": [1, 2, 3], "b": [4, 5, 6], "c": [7, 8, 9]})**In [380]:** dft.loc[:, ["a", "b"]].astype(np.uint8).dtypes**Out[380]:**

```
a    uint8
b    uint8
dtype: object
```

In [381]: dft.loc[:, ["a", "b"]] = dft.loc[:, ["a", "b"]].astype(np.uint8)**In [382]:** dft.dtypes**Out[382]:**

```
a    int64
b    int64
c    int64
dtype: object
```

object conversion

pandas offers various functions to try to force conversion of types from the `object` dtype to other types. In cases where the data is already of the correct type, but stored in an `object` array, the `DataFrame.infer_objects()` and `Series.infer_objects()` methods can be used to soft convert to the correct type.

In [383]: import datetime

```
In [384]: df = pd.DataFrame(
    ....:     [
    ....:         [1, 2],
    ....:         ["a", "b"],
    ....:         [datetime.datetime(2016, 3, 2), datetime.datetime(2016, 3, 2)],
    ....:     ],
    ....:     [
    ....:     ]
    ....: )
```

In [385]: df = df.T**In [386]:** df

(continues on next page)

(continued from previous page)

Out[386]:

```
0    1        2  
0    1    a 2016-03-02  
1    2    b 2016-03-02
```

In [387]: df.dtypes**Out[387]:**

```
0            object  
1            object  
2    datetime64[ns]  
dtype: object
```

Because the data was transposed the original inference stored all columns as object, which `infer_objects` will correct.

In [388]: df.infer_objects().dtypes**Out[388]:**

```
0        int64  
1        object  
2    datetime64[ns]  
dtype: object
```

The following functions are available for one dimensional object arrays or scalars to perform hard conversion of objects to a specified type:

- `to_numeric()` (conversion to numeric dtypes)

In [389]: m = ["1.1", 2, 3]**In [390]:** pd.to_numeric(m)**Out[390]:** array([1.1, 2., 3.])

- `to_datetime()` (conversion to datetime objects)

In [391]: import datetime**In [392]:** m = ["2016-07-09", datetime.datetime(2016, 3, 2)]**In [393]:** pd.to_datetime(m)**Out[393]:** DatetimeIndex(['2016-07-09', '2016-03-02'], dtype='datetime64[ns]', freq=None)

- `to_timedelta()` (conversion to timedelta objects)

In [394]: m = ["5us", pd.Timedelta("1day")]**In [395]:** pd.to_timedelta(m)**Out[395]:** TimedeltaIndex(['0 days 00:00:00.000005', '1 days 00:00:00'], dtype='timedelta64[ns]', freq=None)

To force a conversion, we can pass in an `errors` argument, which specifies how pandas should deal with elements that cannot be converted to desired dtype or object. By default, `errors='raise'`, meaning that any errors encountered will be raised during the conversion process. However, if `errors='coerce'`, these errors will be ignored and pandas will convert problematic elements to `pd.NaT` (for datetime and timedelta) or `np.nan` (for numeric). This might be

useful if you are reading in data which is mostly of the desired dtype (e.g. numeric, datetime), but occasionally has non-conforming elements intermixed that you want to represent as missing:

```
In [396]: import datetime

In [397]: m = ["apple", datetime.datetime(2016, 3, 2)]

In [398]: pd.to_datetime(m, errors="coerce")
Out[398]: DatetimeIndex(['NaT', '2016-03-02'], dtype='datetime64[ns]', freq=None)

In [399]: m = ["apple", 2, 3]

In [400]: pd.to_numeric(m, errors="coerce")
Out[400]: array([nan, 2., 3.])

In [401]: m = ["apple", pd.Timedelta("1day")]

In [402]: pd.to_timedelta(m, errors="coerce")
Out[402]: TimedeltaIndex(['NaT', '1 days'], dtype='timedelta64[ns]', freq=None)
```

The `errors` parameter has a third option of `errors='ignore'`, which will simply return the passed in data if it encounters any errors with the conversion to a desired data type:

```
In [403]: import datetime

In [404]: m = ["apple", datetime.datetime(2016, 3, 2)]

In [405]: pd.to_datetime(m, errors="ignore")
Out[405]: Index(['apple', 2016-03-02 00:00:00], dtype='object')

In [406]: m = ["apple", 2, 3]

In [407]: pd.to_numeric(m, errors="ignore")
Out[407]: array(['apple', 2, 3], dtype=object)

In [408]: m = ["apple", pd.Timedelta("1day")]

In [409]: pd.to_timedelta(m, errors="ignore")
Out[409]: array(['apple', Timedelta('1 days 00:00:00')], dtype=object)
```

In addition to object conversion, `to_numeric()` provides another argument `downcast`, which gives the option of downcasting the newly (or already) numeric data to a smaller dtype, which can conserve memory:

```
In [410]: m = [1, 2, 3]

In [411]: pd.to_numeric(m, downcast="integer") # smallest signed int dtype
Out[411]: array([1, 2, 3], dtype=int8)

In [412]: pd.to_numeric(m, downcast="signed") # same as 'integer'
Out[412]: array([1, 2, 3], dtype=int8)

In [413]: pd.to_numeric(m, downcast="unsigned") # smallest unsigned int dtype
Out[413]: array([1, 2, 3], dtype=uint8)
```

(continues on next page)

(continued from previous page)

```
In [414]: pd.to_numeric(m, downcast="float") # smallest float dtype
Out[414]: array([1., 2., 3.], dtype=float32)
```

As these methods apply only to one-dimensional arrays, lists or scalars; they cannot be used directly on multi-dimensional objects such as DataFrames. However, with `apply()`, we can “apply” the function over each column efficiently:

```
In [415]: import datetime

In [416]: df = pd.DataFrame([["2016-07-09", datetime.datetime(2016, 3, 2)]] * 2, dtype="O"
   ..)

In [417]: df
Out[417]:
      0           1
0 2016-07-09 2016-03-02 00:00:00
1 2016-07-09 2016-03-02 00:00:00

In [418]: df.apply(pd.to_datetime)
Out[418]:
      0           1
0 2016-07-09 2016-03-02
1 2016-07-09 2016-03-02

In [419]: df = pd.DataFrame([[1.1, 2, 3]] * 2, dtype="O")

In [420]: df
Out[420]:
      0  1  2
0  1.1 2  3
1  1.1 2  3

In [421]: df.apply(pd.to_numeric)
Out[421]:
      0  1  2
0  1.1 2  3
1  1.1 2  3

In [422]: df = pd.DataFrame([["5us", pd.Timedelta("1day")]] * 2, dtype="O")

In [423]: df
Out[423]:
      0           1
0 5us 1 days 00:00:00
1 5us 1 days 00:00:00

In [424]: df.apply(pd.to_timedelta)
Out[424]:
      0           1
0 0 days 00:00:00.000005 1 days
1 0 days 00:00:00.000005 1 days
```

gotchas

Performing selection operations on `integer` type data can easily upcast the data to `floating`. The dtype of the input data will be preserved in cases where `nans` are not introduced. See also [Support for integer NA](#).

```
In [425]: dfi = df3.astype("int32")
```

```
In [426]: dfi["E"] = 1
```

```
In [427]: dfi
```

```
Out[427]:
```

	A	B	C	E

B    float64
C    float64
dtype: object
```

2.3.14 Selecting columns based on dtype

The `select_dtypes()` method implements subsetting of columns based on their `dtype`.

First, let's create a `DataFrame` with a slew of different dtypes:

```
In [438]: df = pd.DataFrame(
    ....:     {
    ....:         "string": list("abc"),
    ....:         "int64": list(range(1, 4)),
    ....:         "uint8": np.arange(3, 6).astype("u1"),
    ....:         "float64": np.arange(4.0, 7.0),
    ....:         "bool1": [True, False, True],
    ....:         "bool2": [False, True, False],
    ....:         "dates": pd.date_range("now", periods=3),
    ....:         "category": pd.Series(list("ABC")).astype("category"),
    ....:     }
    ....: )
```

(continues on next page)

(continued from previous page)

```
In [439]: df["tdeltas"] = df.dates.diff()

In [440]: df["uint64"] = np.arange(3, 6).astype("u8")

In [441]: df["other_dates"] = pd.date_range("20130101", periods=3)

In [442]: df["tz_aware_dates"] = pd.date_range("20130101", periods=3, tz="US/Eastern")

In [443]: df
Out[443]:
   string  int64  uint8  float64  bool1 ... category  tdeltas  uint64  other_dates
0      a      1       3      4.0   True ...          A        NaT      3  2013-01-01 2013-01-
   ↵      01 00:00:00-05:00
1      b      2       4      5.0  False ...          B    1 days      4  2013-01-02 2013-01-
   ↵      02 00:00:00-05:00
2      c      3       5      6.0   True ...          C    1 days      5  2013-01-03 2013-01-
   ↵      03 00:00:00-05:00

[3 rows x 12 columns]
```

And the dtypes:

```
In [444]: df.dtypes
Out[444]:
string                      object
int64                       int64
uint8                        uint8
float64                     float64
bool1                        bool
bool2                        bool
dates                         datetime64[ns]
category                     category
tdeltas                      timedelta64[ns]
uint64                       uint64
other_dates                  datetime64[ns]
tz_aware_dates    datetime64[ns, US/Eastern]
dtype: object
```

`select_dtypes()` has two parameters `include` and `exclude` that allow you to say “give me the columns *with* these dtypes” (`include`) and/or “give the columns *without* these dtypes” (`exclude`).

For example, to select `bool` columns:

```
In [445]: df.select_dtypes(include=[bool])
Out[445]:
   bool1  bool2
0   True  False
1  False   True
2   True  False
```

You can also pass the name of a dtype in the NumPy dtype hierarchy:

```
In [446]: df.select_dtypes(include=["bool"])
Out[446]:
   bool1  bool2
0    True  False
1  False   True
2   True  False
```

`select_dtypes()` also works with generic dtypes as well.

For example, to select all numeric and boolean columns while excluding unsigned integers:

```
In [447]: df.select_dtypes(include=["number", "bool"], exclude=["unsignedinteger"])
Out[447]:
   int64  float64  bool1  bool2  tdeltas
0      1        4.0   True  False     NaT
1      2        5.0  False   True  1 days
2      3        6.0   True  False  1 days
```

To select string columns you must use the `object` dtype:

```
In [448]: df.select_dtypes(include=["object"])
Out[448]:
   string
0      a
1      b
2      c
```

To see all the child dtypes of a generic dtype like `numpy.number` you can define a function that returns a tree of child dtypes:

```
In [449]: def subdtypes(dtype):
....:     subs = dtype.__subclasses__()
....:     if not subs:
....:         return dtype
....:     return [dtype, [subdtypes(dt) for dt in subs]]
```

All NumPy dtypes are subclasses of `numpy.generic`:

```
In [450]: subdtypes(np.generic)
Out[450]:
[numpy.generic,
 [[numpy.number,
  [[numpy.integer,
   [[numpy.signedinteger,
    [numpy.int8,
     numpy.int16,
     numpy.int32,
     numpy.int64,
     numpy.longlong,
     numpy.timedelta64]],
    [numpy.unsignedinteger,
     [numpy.uint8,
      numpy.uint16,
```

(continues on next page)

(continued from previous page)

```

numpy.uint32,
numpy.uint64,
numpy.ulonglong]]], ,
[numpy.inexact,
[[numpy.floating,
[numpy.float16, numpy.float32, numpy.float64, numpy.float128]],
[numpy.complexfloating,
[numpy.complex64, numpy.complex128, numpy.complex256]]]], ,
[numpy.flexible,
[[numpy.character, [numpy.bytes_, numpy.str_]],
[numpy.void, [numpy.record]]]],
numpy.bool_,
numpy.datetime64,
numpy.object_]

```

Note: pandas also defines the types `category`, and `datetime64[ns, tz]`, which are not integrated into the normal NumPy hierarchy and won't show up with the above function.

2.4 IO tools (text, CSV, HDF5, ...)

The pandas I/O API is a set of top level `reader` functions accessed like `pandas.read_csv()` that generally return a pandas object. The corresponding `writer` functions are object methods that are accessed like `DataFrame.to_csv()`. Below is a table containing available `readers` and `writers`.

Format Type	Data Description	Reader	Writer
text	CSV	<code>read_csv</code>	<code>to_csv</code>
text	Fixed-Width Text File	<code>read_fwf</code>	
text	JSON	<code>read_json</code>	<code>to_json</code>
text	HTML	<code>read_html</code>	<code>to_html</code>
text	LaTeX		<code>Styler.to_latex</code>
text	XML	<code>read_xml</code>	<code>to_xml</code>
text	Local clipboard	<code>read_clipboard</code>	<code>to_clipboard</code>
binary	MS Excel	<code>read_excel</code>	<code>to_excel</code>
binary	OpenDocument	<code>read_excel</code>	
binary	HDF5 Format	<code>read_hdf</code>	<code>to_hdf</code>
binary	Feather Format	<code>read_feather</code>	<code>to_feather</code>
binary	Parquet Format	<code>read_parquet</code>	<code>to_parquet</code>
binary	ORC Format	<code>read_orc</code>	
binary	Stata	<code>read_stata</code>	<code>to_stata</code>
binary	SAS	<code>read_sas</code>	
binary	SPSS	<code>read_spss</code>	
binary	Python Pickle Format	<code>read_pickle</code>	<code>to_pickle</code>
SQL	SQL	<code>read_sql</code>	<code>to_sql</code>
SQL	Google BigQuery	<code>read_gbq</code>	<code>to_gbq</code>

[Here](#) is an informal performance comparison for some of these IO methods.

Note: For examples that use the `StringIO` class, make sure you import it with `from io import StringIO` for Python 3.

2.4.1 CSV & text files

The workhorse function for reading text files (a.k.a. flat files) is `read_csv()`. See the *cookbook* for some advanced strategies.

Parsing options

`read_csv()` accepts the following common arguments:

Basic

filepath_or_buffer [various] Either a path to a file (a `str`, `pathlib.Path`, or `py:py._path.local.LocalPath`), URL (including http, ftp, and S3 locations), or any object with a `read()` method (such as an open file or `StringIO`).

sep [str, defaults to ',' for `read_csv()`, '\t' for `read_table()`] Delimiter to use. If `sep` is `None`, the C engine cannot automatically detect the separator, but the Python parsing engine can, meaning the latter will be used and automatically detect the separator by Python's builtin sniffer tool, `csv.Sniffer`. In addition, separators longer than 1 character and different from '`\s+`' will be interpreted as regular expressions and will also force the use of the Python parsing engine. Note that regex delimiters are prone to ignoring quoted data. Regex example: '`\r\t`'.

delimiter [str, default `None`] Alternative argument name for `sep`.

delim_whitespace [boolean, default `False`] Specifies whether or not whitespace (e.g. ' ' or '\t') will be used as the delimiter. Equivalent to setting `sep='\s+'`. If this option is set to `True`, nothing should be passed in for the `delimiter` parameter.

Column and index locations and names

header [int or list of ints, default 'infer'] Row number(s) to use as the column names, and the start of the data. Default behavior is to infer the column names: if no names are passed the behavior is identical to `header=0` and column names are inferred from the first line of the file, if column names are passed explicitly then the behavior is identical to `header=None`. Explicitly pass `header=0` to be able to replace existing names.

The header can be a list of ints that specify row locations for a MultiIndex on the columns e.g. `[0, 1, 3]`. Intervening rows that are not specified will be skipped (e.g. 2 in this example is skipped). Note that this parameter ignores commented lines and empty lines if `skip_blank_lines=True`, so `header=0` denotes the first line of data rather than the first line of the file.

names [array-like, default `None`] List of column names to use. If file contains no header row, then you should explicitly pass `header=None`. Duplicates in this list are not allowed.

index_col [int, str, sequence of int / str, or `False`, optional, default `None`] Column(s) to use as the row labels of the `DataFrame`, either given as string name or column index. If a sequence of int / str is given, a MultiIndex is used.

Note: `index_col=False` can be used to force pandas to *not* use the first column as the index, e.g. when you have a malformed file with delimiters at the end of each line.

The default value of `None` instructs pandas to guess. If the number of fields in the column header row is equal to the number of fields in the body of the data file, then a default index is used. If it is larger, then the first columns are used as index so that the remaining number of fields in the body are equal to the number of fields in the header.

The first row after the header is used to determine the number of columns, which will go into the index. If the subsequent rows contain less columns than the first row, they are filled with `NaN`.

This can be avoided through `usecols`. This ensures that the columns are taken as is and the trailing data are ignored.

usecols [list-like or callable, default `None`] Return a subset of the columns. If list-like, all elements must either be positional (i.e. integer indices into the document columns) or strings that correspond to column names provided either by the user in `names` or inferred from the document header row(s). If `names` are given, the document header row(s) are not taken into account. For example, a valid list-like `usecols` parameter would be `[0, 1, 2]` or `['foo', 'bar', 'baz']`.

Element order is ignored, so `usecols=[0, 1]` is the same as `[1, 0]`. To instantiate a DataFrame from data with element order preserved use `pd.read_csv(data, usecols=['foo', 'bar'])[['foo', 'bar']]` for columns in `['foo', 'bar']` order or `pd.read_csv(data, usecols=['foo', 'bar'])[['bar', 'foo']]` for `['bar', 'foo']` order.

If callable, the callable function will be evaluated against the column names, returning names where the callable function evaluates to True:

```
In [1]: import pandas as pd
In [2]: from io import StringIO
In [3]: data = "col1,col2,col3\na,b,1\na,b,2\nnc,d,3"
In [4]: pd.read_csv(StringIO(data))
Out[4]:
   col1  col2  col3
0     a      b      1
1     a      b      2
2     c      d      3

In [5]: pd.read_csv(StringIO(data), usecols=lambda x: x.upper() in ["COL1", "COL3"])
Out[5]:
   col1  col3
0     a      1
1     a      2
2     c      3
```

Using this parameter results in much faster parsing time and lower memory usage when using the `c` engine. The Python engine loads the data first before deciding which columns to drop.

squeeze [boolean, default `False`] If the parsed data only contains one column then return a `Series`.

Deprecated since version 1.4.0: Append `.squeeze("columns")` to the call to `{func_name}` to squeeze the data.

prefix [str, default `None`] Prefix to add to column numbers when no header, e.g. 'X' for X0, X1, ...

Deprecated since version 1.4.0: Use a list comprehension on the DataFrame's columns after calling `read_csv`.

```
In [6]: data = "col1,col2,col3\na,b,1"
In [7]: df = pd.read_csv(StringIO(data))
In [8]: df.columns = [f"pre_{col}" for col in df.columns]
In [9]: df
Out[9]:
   pre_col1  pre_col2  pre_col3
0          a         b         1
```

mangle_dupe_cols [boolean, default True] Duplicate columns will be specified as ‘X’, ‘X.1’… ‘X.N’, rather than ‘X’…‘X’. Passing in False will cause data to be overwritten if there are duplicate names in the columns.

General parsing configuration

dtype [Type name or dict of column -> type, default None] Data type for data or columns. E.g. {'a': np.float64, 'b': np.int32} (unsupported with engine='python'). Use str or object together with suitable na_values settings to preserve and not interpret dtype.

engine [{'c', 'python', 'pyarrow'}] Parser engine to use. The C and pyarrow engines are faster, while the python engine is currently more feature-complete. Multithreading is currently only supported by the pyarrow engine.

New in version 1.4.0: The “pyarrow” engine was added as an *experimental* engine, and some features are unsupported, or may not work correctly, with this engine.

converters [dict, default None] Dict of functions for converting values in certain columns. Keys can either be integers or column labels.

true_values [list, default None] Values to consider as True.

false_values [list, default None] Values to consider as False.

skipinitialspace [boolean, default False] Skip spaces after delimiter.

skiprows [list-like or integer, default None] Line numbers to skip (0-indexed) or number of lines to skip (int) at the start of the file.

If callable, the callable function will be evaluated against the row indices, returning True if the row should be skipped and False otherwise:

```
In [10]: data = "col1,col2,col3\na,b,1\na,b,2\n\nc,d,3"
In [11]: pd.read_csv(StringIO(data))
Out[11]:
   col1  col2  col3
0     a     b     1
1     a     b     2
2     c     d     3

In [12]: pd.read_csv(StringIO(data), skiprows=lambda x: x % 2 != 0)
Out[12]:
   col1  col2  col3
0     a     b     2
```

skipfooter [int, default 0] Number of lines at bottom of file to skip (unsupported with engine='c').

nrows [int, default None] Number of rows of file to read. Useful for reading pieces of large files.

low_memory [boolean, default True] Internally process the file in chunks, resulting in lower memory use while parsing, but possibly mixed type inference. To ensure no mixed types either set `False`, or specify the type with the `dtype` parameter. Note that the entire file is read into a single `DataFrame` regardless, use the `chunksize` or `iterator` parameter to return the data in chunks. (Only valid with C parser)

memory_map [boolean, default False] If a filepath is provided for `filepath_or_buffer`, map the file object directly onto memory and access the data directly from there. Using this option can improve performance because there is no longer any I/O overhead.

NA and missing data handling

na_values [scalar, str, list-like, or dict, default None] Additional strings to recognize as NA/NaN. If dict passed, specific per-column NA values. See [na values const](#) below for a list of the values interpreted as NaN by default.

keep_default_na [boolean, default True] Whether or not to include the default NaN values when parsing the data. Depending on whether `na_values` is passed in, the behavior is as follows:

- If `keep_default_na` is `True`, and `na_values` are specified, `na_values` is appended to the default NaN values used for parsing.
- If `keep_default_na` is `True`, and `na_values` are not specified, only the default NaN values are used for parsing.
- If `keep_default_na` is `False`, and `na_values` are specified, only the NaN values specified `na_values` are used for parsing.
- If `keep_default_na` is `False`, and `na_values` are not specified, no strings will be parsed as NaN.

Note that if `na_filter` is passed in as `False`, the `keep_default_na` and `na_values` parameters will be ignored.

na_filter [boolean, default True] Detect missing value markers (empty strings and the value of `na_values`). In data without any NAs, passing `na_filter=False` can improve the performance of reading a large file.

verbose [boolean, default False] Indicate number of NA values placed in non-numeric columns.

skip_blank_lines [boolean, default True] If `True`, skip over blank lines rather than interpreting as NaN values.

Datetime handling

parse_dates [boolean or list of ints or names or list of lists or dict, default False.]

- If `True` -> try parsing the index.
- If `[1, 2, 3]` -> try parsing columns 1, 2, 3 each as a separate date column.
- If `[[1, 3]]` -> combine columns 1 and 3 and parse as a single date column.
- If `{'foo': [1, 3]}` -> parse columns 1, 3 as date and call result 'foo'. A fast-path exists for iso8601-formatted dates.

infer_datetime_format [boolean, default False] If `True` and `parse_dates` is enabled for a column, attempt to infer the datetime format to speed up the processing.

keep_date_col [boolean, default False] If `True` and `parse_dates` specifies combining multiple columns then keep the original columns.

date_parser [function, default None] Function to use for converting a sequence of string columns to an array of datetime instances. The default uses `dateutil.parser.parser` to do the conversion. pandas will try to call `date_parser` in three different ways, advancing to the next if an exception occurs: 1) Pass one or more arrays (as defined by `parse_dates`) as arguments; 2) concatenate (row-wise) the string values from the columns defined by `parse_dates` into a single array and pass that; and 3) call `date_parser` once for each row using one or more strings (corresponding to the columns defined by `parse_dates`) as arguments.

dayfirst [boolean, default False] DD/MM format dates, international and European format.

cache_dates [boolean, default True] If True, use a cache of unique, converted dates to apply the datetime conversion. May produce significant speed-up when parsing duplicate date strings, especially ones with timezone offsets.

New in version 0.25.0.

Iteration

iterator [boolean, default False] Return `TextFileReader` object for iteration or getting chunks with `get_chunk()`.

chunksize [int, default None] Return `TextFileReader` object for iteration. See [iterating and chunking](#) below.

Quoting, compression, and file format

compression [{`'infer'`, `'gzip'`, `'bz2'`, `'zip'`, `'xz'`, `'zstd'`, `None`, `dict`}, default `'infer'`] For on-the-fly decompression of on-disk data. If `'infer'`, then use gzip, bz2, zip, xz, or zstandard if `filepath_or_buffer` is path-like ending in `'.gz'`, `'.bz2'`, `'.zip'`, `'.xz'`, `'.zst'`, respectively, and no decompression otherwise. If using `'zip'`, the ZIP file must contain only one data file to be read in. Set to `None` for no decompression. Can also be a dict with key `'method'` set to one of `{'zip', 'gzip', 'bz2', 'zstd'}` and other key-value pairs are forwarded to `zipfile.ZipFile`, `gzip.GzipFile`, `bz2.BZ2File`, or `zstandard.ZstdDecompressor`. As an example, the following could be passed for faster compression and to create a reproducible gzip archive: `compression={'method': 'gzip', 'compresslevel': 1, 'mtime': 1}`.

Changed in version 1.1.0: dict option extended to support `gzip` and `bz2`.

Changed in version 1.2.0: Previous versions forwarded dict entries for `'gzip'` to `gzip.open`.

thousands [str, default `None`] Thousands separator.

decimal [str, default `'.'`] Character to recognize as decimal point. E.g. use `','` for European data.

float_precision [string, default `None`] Specifies which converter the C engine should use for floating-point values. The options are `None` for the ordinary converter, `high` for the high-precision converter, and `round_trip` for the round-trip converter.

lineterminator [str (length 1), default `None`] Character to break file into lines. Only valid with C parser.

quotechar [str (length 1)] The character used to denote the start and end of a quoted item. Quoted items can include the delimiter and it will be ignored.

quoting [int or `csv.QUOTE_*` instance, default `0`] Control field quoting behavior per `csv.QUOTE_*` constants. Use one of `QUOTE_MINIMAL` (0), `QUOTE_ALL` (1), `QUOTE_NONNUMERIC` (2) or `QUOTE_NONE` (3).

doublequote [boolean, default True] When `quotechar` is specified and `quoting` is not `QUOTE_NONE`, indicate whether or not to interpret two consecutive `quotechar` elements **inside** a field as a single `quotechar` element.

escapechar [str (length 1), default `None`] One-character string used to escape delimiter when `quoting` is `QUOTE_NONE`.

comment [str, default `None`] Indicates remainder of line should not be parsed. If found at the beginning of a line, the line will be ignored altogether. This parameter must be a single character. Like empty lines (as long as `skip_blank_lines=True`), fully commented lines are ignored by the parameter `header` but not by `skiprows`.

For example, if `comment='#'`, parsing '#empty\na,b,c\n1,2,3' with `header=0` will result in 'a,b,c' being treated as the header.

encoding [str, default None] Encoding to use for UTF when reading/writing (e.g. 'utf-8'). [List of Python standard encodings](#).

dialect [str or `csv.Dialect` instance, default None] If provided, this parameter will override values (default or not) for the following parameters: `delimiter`, `doublequote`, `escapechar`, `skipinitialspace`, `quotechar`, and `quoting`. If it is necessary to override values, a `ParserWarning` will be issued. See `csv.Dialect` documentation for more details.

Error handling

error_bad_lines [boolean, optional, default None] Lines with too many fields (e.g. a csv line with too many commas) will by default cause an exception to be raised, and no `DataFrame` will be returned. If `False`, then these “bad lines” will dropped from the `DataFrame` that is returned. See [bad lines](#) below.

Deprecated since version 1.3.0: The `on_bad_lines` parameter should be used instead to specify behavior upon encountering a bad line instead.

warn_bad_lines [boolean, optional, default None] If `error_bad_lines` is `False`, and `warn_bad_lines` is `True`, a warning for each “bad line” will be output.

Deprecated since version 1.3.0: The `on_bad_lines` parameter should be used instead to specify behavior upon encountering a bad line instead.

on_bad_lines [(‘error’, ‘warn’, ‘skip’), default ‘error’] Specifies what to do upon encountering a bad line (a line with too many fields). Allowed values are :

- ‘error’, raise an `ParserError` when a bad line is encountered.
- ‘warn’, print a warning when a bad line is encountered and skip that line.
- ‘skip’, skip bad lines without raising or warning when they are encountered.

New in version 1.3.0.

Specifying column data types

You can indicate the data type for the whole `DataFrame` or individual columns:

In [13]: `import numpy as np`

In [14]: `data = "a,b,c,d\n1,2,3,4\n5,6,7,8\n9,10,11"`

In [15]: `print(data)`

```
a,b,c,d
1,2,3,4
5,6,7,8
9,10,11
```

In [16]: `df = pd.read_csv(StringIO(data), dtype=object)`

In [17]: `df`

Out[17]:

	a	b	c	d
0	1	2	3	4

(continues on next page)

(continued from previous page)

```
1 5 6 7 8
2 9 10 11 NaN
```

In [18]: df["a"][0]
Out[18]: '1'

In [19]: df = pd.read_csv(StringIO(data), dtype={"b": object, "c": np.float64, "d": "Int64"})

In [20]: df.dtypes
Out[20]:

a	int64
b	object
c	float64
d	Int64
dtype:	object

Fortunately, pandas offers more than one way to ensure that your column(s) contain only one `dtype`. If you're unfamiliar with these concepts, you can see [here](#) to learn more about dtypes, and [here](#) to learn more about `object` conversion in pandas.

For instance, you can use the `converters` argument of `read_csv()`:

In [21]: data = "col_1\n1\n2\n'A'\n4.22"

In [22]: df = pd.read_csv(StringIO(data), converters={"col_1": str})

In [23]: df
Out[23]:

col_1
0 1
1 2
2 'A'
3 4.22

In [24]: df["col_1"].apply(type).value_counts()
Out[24]:

<class 'str'>	4
Name: col_1, dtype: int64	

Or you can use the `to_numeric()` function to coerce the dtypes after reading in the data,

In [25]: df2 = pd.read_csv(StringIO(data))

In [26]: df2["col_1"] = pd.to_numeric(df2["col_1"], errors="coerce")

In [27]: df2
Out[27]:

col_1
0 1.00
1 2.00
2 NaN
3 4.22

(continues on next page)

(continued from previous page)

```
In [28]: df2["col_1"].apply(type).value_counts()
Out[28]:
<class 'float'>    4
Name: col_1, dtype: int64
```

which will convert all valid parsing to floats, leaving the invalid parsing as NaN.

Ultimately, how you deal with reading in columns containing mixed dtypes depends on your specific needs. In the case above, if you wanted to NaN out the data anomalies, then `to_numeric()` is probably your best option. However, if you wanted for all the data to be coerced, no matter the type, then using the `converters` argument of `read_csv()` would certainly be worth trying.

Note: In some cases, reading in abnormal data with columns containing mixed dtypes will result in an inconsistent dataset. If you rely on pandas to infer the dtypes of your columns, the parsing engine will go and infer the dtypes for different chunks of the data, rather than the whole dataset at once. Consequently, you can end up with column(s) with mixed dtypes. For example,

```
In [29]: col_1 = list(range(500000)) + ["a", "b"] + list(range(500000))

In [30]: df = pd.DataFrame({"col_1": col_1})

In [31]: df.to_csv("foo.csv")

In [32]: mixed_df = pd.read_csv("foo.csv")

In [33]: mixed_df["col_1"].apply(type).value_counts()
Out[33]:
<class 'int'>    737858
<class 'str'>    262144
Name: col_1, dtype: int64

In [34]: mixed_df["col_1"].dtype
Out[34]: dtype('O')
```

will result with `mixed_df` containing an `int` dtype for certain chunks of the column, and `str` for others due to the mixed dtypes from the data that was read in. It is important to note that the overall column will be marked with a dtype of `object`, which is used for columns with mixed dtypes.

Specifying categorical dtype

Categorical columns can be parsed directly by specifying `dtype='category'` or `dtype=CategoricalDtype(categories, ordered)`.

```
In [35]: data = "col1,col2,col3\na,b,1\na,b,2\nnc,d,3"

In [36]: pd.read_csv(StringIO(data))
Out[36]:
   col1  col2  col3
0     a     b     1
1     a     b     2
```

(continues on next page)

(continued from previous page)

```
2    c    d    3
In [37]: pd.read_csv(StringIO(data)).dtypes
Out[37]:
col1    object
col2    object
col3    int64
dtype: object

In [38]: pd.read_csv(StringIO(data), dtype="category").dtypes
Out[38]:
col1    category
col2    category
col3    category
dtype: object
```

Individual columns can be parsed as a `Categorical` using a dict specification:

```
In [39]: pd.read_csv(StringIO(data), dtype={"col1": "category"}).dtypes
Out[39]:
col1    category
col2    object
col3    int64
dtype: object
```

Specifying `dtype='category'` will result in an unordered `Categorical` whose `categories` are the unique values observed in the data. For more control on the categories and order, create a `CategoricalDtype` ahead of time, and pass that for that column's `dtype`.

```
In [40]: from pandas.api.types import CategoricalDtype
In [41]: dtype = CategoricalDtype(["d", "c", "b", "a"], ordered=True)
In [42]: pd.read_csv(StringIO(data), dtype={"col1": dtype}).dtypes
Out[42]:
col1    category
col2    object
col3    int64
dtype: object
```

When using `dtype=CategoricalDtype`, “unexpected” values outside of `dtype.categories` are treated as missing values.

```
In [43]: dtype = CategoricalDtype(["a", "b", "d"]) # No 'c'
In [44]: pd.read_csv(StringIO(data), dtype={"col1": dtype}).col1
Out[44]:
0      a
1      a
2    NaN
Name: col1, dtype: category
Categories (3, object): ['a', 'b', 'd']
```

This matches the behavior of `Categorical.set_categories()`.

Note: With `dtype='category'`, the resulting categories will always be parsed as strings (object dtype). If the categories are numeric they can be converted using the `to_numeric()` function, or as appropriate, another converter such as `to_datetime()`.

When `dtype` is a `CategoricalDtype` with homogeneous `categories` (all numeric, all datetimes, etc.), the conversion is done automatically.

```
In [45]: df = pd.read_csv(StringIO(data), dtype="category")
```

```
In [46]: df.dtypes
```

```
Out[46]:
```

```
col1    category
col2    category
col3    category
dtype: object
```

```
In [47]: df["col3"]
```

```
Out[47]:
```

```
0    1
1    2
2    3
Name: col3, dtype: category
Categories (3, object): ['1', '2', '3']
```

```
In [48]: df["col3"].cat.categories = pd.to_numeric(df["col3"].cat.categories)
```

```
In [49]: df["col3"]
```

```
Out[49]:
```

```
0    1
1    2

```

Naming and using columns

Handling column names

A file may or may not have a header row. pandas assumes the first row should be used as the column names:

```
In [50]: data = "a,b,c\n1,2,3\n4,5,6\n7,8,9"
```

```
In [51]: print(data)
```

```
a,b,c
1,2,3
4,5,6
7,8,9
```

```
In [52]: pd.read_csv(StringIO(data))
```

(continues on next page)

(continued from previous page)

Out[52]:

```
a   b   c  
0   1   2   3  
1   4   5   6  
2   7   8   9
```

By specifying the `names` argument in conjunction with `header` you can indicate other names to use and whether or not to throw away the header row (if any):

In [53]: `print(data)`

```
a,b,c  
1,2,3  
4,5,6  
7,8,9
```

In [54]: `pd.read_csv(StringIO(data), names=["foo", "bar", "baz"], header=0)`**Out[54]:**

```
foo   bar   baz  
0     1     2     3  
1     4     5     6  
2     7     8     9
```

In [55]: `pd.read_csv(StringIO(data), names=["foo", "bar", "baz"], header=None)`**Out[55]:**

```
foo bar baz  
0   a   b   c  
1   1   2   3  
2   4   5   6  
3   7   8   9
```

If the header is in a row other than the first, pass the row number to `header`. This will skip the preceding rows:

In [56]: `data = "skip this skip it\na,b,c\n1,2,3\n4,5,6\n7,8,9"`**In [57]:** `pd.read_csv(StringIO(data), header=1)`**Out[57]:**

```
a   b   c  
0   1   2   3  
1   4   5   6  
2   7   8   9
```

Note: Default behavior is to infer the column names: if no names are passed the behavior is identical to `header=0` and column names are inferred from the first non-blank line of the file, if column names are passed explicitly then the behavior is identical to `header=None`.

Duplicate names parsing

If the file or header contains duplicate names, pandas will by default distinguish between them so as to prevent over-writing data:

```
In [58]: data = "a,b,a\n0,1,2\n3,4,5"
```

```
In [59]: pd.read_csv(StringIO(data))
```

```
Out[59]:
```

	a	b	a.1
0	0	1	2
1	3	4	5

There is no more duplicate data because `mangle_dupe_cols=True` by default, which modifies a series of duplicate columns ‘X’, …, ‘X’ to become ‘X’, ‘X.1’, …, ‘X.N’. If `mangle_dupe_cols=False`, duplicate data can arise:

```
In [2]: data = 'a,b,a\n0,1,2\n3,4,5'
```

```
In [3]: pd.read_csv(StringIO(data), mangle_dupe_cols=False)
```

```
Out[3]:
```

	a	b	a
0	2	1	2
1	5	4	5

To prevent users from encountering this problem with duplicate data, a `ValueError` exception is raised if `mangle_dupe_cols != True`:

```
In [2]: data = 'a,b,a\n0,1,2\n3,4,5'
```

```
In [3]: pd.read_csv(StringIO(data), mangle_dupe_cols=False)
```

```
...
```

```
ValueError: Setting mangle_dupe_cols=False is not supported yet
```

Filtering columns (usecols)

The `usecols` argument allows you to select any subset of the columns in a file, either using the column names, position numbers or a callable:

```
In [60]: data = "a,b,c,d\n1,2,3,foo\n4,5,6,bar\n7,8,9,baz"
```

```
In [61]: pd.read_csv(StringIO(data))
```

```
Out[61]:
```

	a	b	c	d
0	1	2	3	foo
1	4	5	6	bar
2	7	8	9	baz

```
In [62]: pd.read_csv(StringIO(data), usecols=["b", "d"])
```

```
Out[62]:
```

	b	d
0	2	foo
1	5	bar
2	8	baz

(continues on next page)

(continued from previous page)

In [63]: pd.read_csv(StringIO(data), usecols=[0, 2, 3])**Out[63]:**

	a	c	d
0	1	3	foo
1	4	6	bar
2	7	9	baz

In [64]: pd.read_csv(StringIO(data), usecols=lambda x: x.upper() in ["A", "C"])**Out[64]:**

	a	c
0	1	3
1	4	6
2	7	9

The usecols argument can also be used to specify which columns not to use in the final result:

In [65]: pd.read_csv(StringIO(data), usecols=lambda x: x not in ["a", "c"])**Out[65]:**

	b	d
0	2	foo
1	5	bar
2	8	baz

In this case, the callable is specifying that we exclude the “a” and “c” columns from the output.

Comments and empty lines

Ignoring line comments and empty lines

If the comment parameter is specified, then completely commented lines will be ignored. By default, completely blank lines will be ignored as well.

In [66]: data = "\n a,b,c\n \n# commented line\n 1,2,3\n\n 4,5,6"**In [67]:** print(data)

a,b,c

commented line
1,2,3

4,5,6

In [68]: pd.read_csv(StringIO(data), comment="#")**Out[68]:**

	a	b	c
0	1	2	3
1	4	5	6

If skip_blank_lines=False, then read_csv will not ignore blank lines:

```
In [69]: data = "a,b,c\n\n1,2,3\n\n\n4,5,6"

In [70]: pd.read_csv(StringIO(data), skip_blank_lines=False)
Out[70]:
   a    b    c
0  NaN  NaN  NaN
1  1.0  2.0  3.0
2  NaN  NaN  NaN
3  NaN  NaN  NaN
4  4.0  5.0  6.0
```

Warning: The presence of ignored lines might create ambiguities involving line numbers; the parameter `header` uses row numbers (ignoring commented/empty lines), while `skiprows` uses line numbers (including commented/empty lines):

```
In [71]: data = "#comment\na,b,c\nA,B,C\n1,2,3"

In [72]: pd.read_csv(StringIO(data), comment="#", header=1)
Out[72]:
   A    B    C
0  1    2    3

In [73]: data = "A,B,C\n#comment\na,b,c\n1,2,3"

In [74]: pd.read_csv(StringIO(data), comment="#", skiprows=2)
Out[74]:
   a    b    c
0  1    2    3
```

If both `header` and `skiprows` are specified, `header` will be relative to the end of `skiprows`. For example:

```
In [75]: data = (
....:     "# empty\n"
....:     "# second empty line\n"
....:     "# third emptyline\n"
....:     "X,Y,Z\n"
....:     "1,2,3\n"
....:     "A,B,C\n"
....:     "1,2.,4.\n"
....:     "5.,NaN,10.0\n"
....: )
```

```
In [76]: print(data)
# empty
# second empty line
# third emptyline
X,Y,Z
1,2,3
A,B,C
1,2.,4.
```

(continues on next page)

(continued from previous page)

5.,NaN,10.0

In [77]: pd.read_csv(StringIO(data), comment="#", skiprows=4, header=1)**Out[77]:**

	A	B	C
0	1.0	2.0	4.0
1	5.0	NaN	10.0

Comments

Sometimes comments or meta data may be included in a file:

In [78]: print(open("tmp.csv").read())

ID,level,category

Patient1,123000,x # really unpleasant

Patient2,23000,y # wouldn't take his medicine

Patient3,1234018,z # awesome

By default, the parser includes the comments in the output:

In [79]: df = pd.read_csv("tmp.csv")**In [80]:** df**Out[80]:**

	ID	level	category
0	Patient1	123000	x # really unpleasant
1	Patient2	23000	y # wouldn't take his medicine
2	Patient3	1234018	z # awesome

We can suppress the comments using the `comment` keyword:

In [81]: df = pd.read_csv("tmp.csv", comment="#")**In [82]:** df**Out[82]:**

	ID	level	category
0	Patient1	123000	x
1	Patient2	23000	y
2	Patient3	1234018	z

Dealing with Unicode data

The `encoding` argument should be used for encoded unicode data, which will result in byte strings being decoded to unicode in the result:

In [83]: from io import BytesIO**In [84]:** data = b"word,length\n" b"Tr\xc3\xaaumen,7\n" b"Gr\xc3\xbc\xc3\x9fe,5"

(continues on next page)

(continued from previous page)

```
In [85]: data = data.decode("utf8").encode("latin-1")

In [86]: df = pd.read_csv(BytesIO(data), encoding="latin-1")

In [87]: df
Out[87]:
   word  length
0  Träumen      7
1    Grüße      5

In [88]: df["word"][1]
Out[88]: 'Grüße'
```

Some formats which encode all characters as multiple bytes, like UTF-16, won't parse correctly at all without specifying the encoding. Full list of Python standard encodings.

Index columns and trailing delimiters

If a file has one more column of data than the number of column names, the first column will be used as the DataFrame's row names:

```
In [89]: data = "a,b,c\n4,apple,bat,5.7\n8,orange,cow,10"

In [90]: pd.read_csv(StringIO(data))
Out[90]:
     a     b     c
4  apple   bat   5.7
8  orange   cow  10.0
```

```
In [91]: data = "index,a,b,c\n4,apple,bat,5.7\n8,orange,cow,10"

In [92]: pd.read_csv(StringIO(data), index_col=0)
Out[92]:
     a     b     c
index
4      apple   bat   5.7
8      orange   cow  10.0
```

Ordinarily, you can achieve this behavior using the `index_col` option.

There are some exception cases when a file has been prepared with delimiters at the end of each data line, confusing the parser. To explicitly disable the index column inference and discard the last column, pass `index_col=False`:

```
In [93]: data = "a,b,c\n4,apple,bat,\n8,orange,cow,"

In [94]: print(data)
a,b,c
4,apple,bat,
8,orange,cow,

In [95]: pd.read_csv(StringIO(data))
Out[95]:
```

(continues on next page)

(continued from previous page)

```
a    b    c  
4   apple   bat  NaN  
8  orange   cow  NaN  
  
In [96]: pd.read_csv(StringIO(data), index_col=False)  
Out[96]:  
a    b    c  
0  4   apple   bat  
1  8  orange   cow
```

If a subset of data is being parsed using the `usecols` option, the `index_col` specification is based on that subset, not the original data.

```
In [97]: data = "a,b,c\n4,apple,bat,\n8,orange,cow,"  
  
In [98]: print(data)  
a,b,c  
4,apple,bat,  
8,orange,cow,  
  
In [99]: pd.read_csv(StringIO(data), usecols=["b", "c"])  
Out[99]:  
b    c  
4  bat  NaN  
8  cow  NaN  
  
In [100]: pd.read_csv(StringIO(data), usecols=["b", "c"], index_col=0)  
Out[100]:  
b    c  
4  bat  NaN  
8  cow  NaN
```

Date Handling

Specifying date columns

To better facilitate working with datetime data, `read_csv()` uses the keyword arguments `parse_dates` and `date_parser` to allow users to specify a variety of columns and date/time formats to turn the input text data into `datetime` objects.

The simplest case is to just pass in `parse_dates=True`:

```
# Use a column as an index, and parse it as dates.  
In [101]: df = pd.read_csv("foo.csv", index_col=0, parse_dates=True)  
  
In [102]: df  
Out[102]:  
          A  B  C  
date  
2009-01-01  a  1  2  
2009-01-02  b  3  4
```

(continues on next page)

(continued from previous page)

```
2009-01-03  c  4  5

# These are Python datetime objects
In [103]: df.index
Out[103]: DatetimeIndex(['2009-01-01', '2009-01-02', '2009-01-03'], dtype='datetime64[ns]
˓→', name='date', freq=None)
```

It is often the case that we may want to store date and time data separately, or store various date fields separately. the `parse_dates` keyword can be used to specify a combination of columns to parse the dates and/or times from.

You can specify a list of column lists to `parse_dates`, the resulting date columns will be prepended to the output (so as to not affect the existing column order) and the new column names will be the concatenation of the component column names:

```
In [104]: print(open("tmp.csv").read())
KORD,19990127, 19:00:00, 18:56:00, 0.8100
KORD,19990127, 20:00:00, 19:56:00, 0.0100
KORD,19990127, 21:00:00, 20:56:00, -0.5900
KORD,19990127, 21:00:00, 21:18:00, -0.9900
KORD,19990127, 22:00:00, 21:56:00, -0.5900
KORD,19990127, 23:00:00, 22:56:00, -0.5900
```

```
In [105]: df = pd.read_csv("tmp.csv", header=None, parse_dates=[[1, 2], [1, 3]])
```

```
In [106]: df
```

```
Out[106]:
      1_2          1_3      0      4
0 1999-01-27 19:00:00 1999-01-27 18:56:00  KORD  0.81
1 1999-01-27 20:00:00 1999-01-27 19:56:00  KORD  0.01
2 1999-01-27 21:00:00 1999-01-27 20:56:00  KORD -0.59
3 1999-01-27 21:00:00 1999-01-27 21:18:00  KORD -0.99
4 1999-01-27 22:00:00 1999-01-27 21:56:00  KORD -0.59
5 1999-01-27 23:00:00 1999-01-27 22:56:00  KORD -0.59
```

By default the parser removes the component date columns, but you can choose to retain them via the `keep_date_col` keyword:

```
In [107]: df = pd.read_csv(
.....:     "tmp.csv", header=None, parse_dates=[[1, 2], [1, 3]], keep_date_col=True
.....: )
.....:
```

```
In [108]: df
```

```
Out[108]:
      1_2          1_3      0      1      2      3      4
0 1999-01-27 19:00:00 1999-01-27 18:56:00  KORD  19990127  19:00:00  18:56:00  0.81
1 1999-01-27 20:00:00 1999-01-27 19:56:00  KORD  19990127  20:00:00  19:56:00  0.01
2 1999-01-27 21:00:00 1999-01-27 20:56:00  KORD  19990127  21:00:00  20:56:00 -0.59
3 1999-01-27 21:00:00 1999-01-27 21:18:00  KORD  19990127  21:00:00  21:18:00 -0.99
4 1999-01-27 22:00:00 1999-01-27 21:56:00  KORD  19990127  22:00:00  21:56:00 -0.59
5 1999-01-27 23:00:00 1999-01-27 22:56:00  KORD  19990127  23:00:00  22:56:00 -0.59
```

Note that if you wish to combine multiple columns into a single date column, a nested list must be used. In other words, `parse_dates=[1, 2]` indicates that the second and third columns should each be parsed as separate date columns

while `parse_dates=[[1, 2]]` means the two columns should be parsed into a single column.

You can also use a dict to specify custom name columns:

```
In [109]: date_spec = {"nominal": [1, 2], "actual": [1, 3]}
```

```
In [110]: df = pd.read_csv("tmp.csv", header=None, parse_dates=date_spec)
```

```
In [111]: df
```

```
Out[111]:
```

	nominal	actual	0	4
0	1999-01-27 19:00:00	1999-01-27 18:56:00	KORD	0.81
1	1999-01-27 20:00:00	1999-01-27 19:56:00	KORD	0.01
2	1999-01-27 21:00:00	1999-01-27 20:56:00	KORD	-0.59
3	1999-01-27 21:00:00	1999-01-27 21:18:00	KORD	-0.99
4	1999-01-27 22:00:00	1999-01-27 21:56:00	KORD	-0.59
5	1999-01-27 23:00:00	1999-01-27 22:56:00	KORD	-0.59

It is important to remember that if multiple text columns are to be parsed into a single date column, then a new column is prepended to the data. The `index_col` specification is based off of this new set of columns rather than the original data columns:

```
In [112]: date_spec = {"nominal": [1, 2], "actual": [1, 3]}
```

```
In [113]: df = pd.read_csv(  
.....:     "tmp.csv", header=None, parse_dates=date_spec, index_col=0  
.....: ) # index is the nominal column  
.....:
```

```
In [114]: df
```

```
Out[114]:
```

	nominal	actual	0	4
1999-01-27	19:00:00	1999-01-27 18:56:00	KORD	0.81
1999-01-27	20:00:00	1999-01-27 19:56:00	KORD	0.01
1999-01-27	21:00:00	1999-01-27 20:56:00	KORD	-0.59
1999-01-27	21:00:00	1999-01-27 21:18:00	KORD	-0.99
1999-01-27	22:00:00	1999-01-27 21:56:00	KORD	-0.59
1999-01-27	23:00:00	1999-01-27 22:56:00	KORD	-0.59

Note: If a column or index contains an unparsable date, the entire column or index will be returned unaltered as an object data type. For non-standard datetime parsing, use `to_datetime()` after `pd.read_csv`.

Note: `read_csv` has a fast_path for parsing datetime strings in iso8601 format, e.g “2000-01-01T00:01:02+00:00” and similar variations. If you can arrange for your data to store datetimes in this format, load times will be significantly faster, ~20x has been observed.

Date parsing functions

Finally, the parser allows you to specify a custom `date_parser` function to take full advantage of the flexibility of the date parsing API:

```
In [115]: df = pd.read_csv(
.....:     "tmp.csv", header=None, parse_dates=date_spec, date_parser=pd.to_datetime
.....: )
.....:

In [116]: df
Out[116]:
      nominal          actual    0    4
0 1999-01-27 19:00:00 1999-01-27 18:56:00  KORD  0.81
1 1999-01-27 20:00:00 1999-01-27 19:56:00  KORD  0.01
2 1999-01-27 21:00:00 1999-01-27 20:56:00  KORD -0.59
3 1999-01-27 21:00:00 1999-01-27 21:18:00  KORD -0.99
4 1999-01-27 22:00:00 1999-01-27 21:56:00  KORD -0.59
5 1999-01-27 23:00:00 1999-01-27 22:56:00  KORD -0.59
```

pandas will try to call the `date_parser` function in three different ways. If an exception is raised, the next one is tried:

1. `date_parser` is first called with one or more arrays as arguments, as defined using `parse_dates` (e.g., `date_parser(['2013', '2013'], ['1', '2'])`).
2. If #1 fails, `date_parser` is called with all the columns concatenated row-wise into a single array (e.g., `date_parser(['2013 1', '2013 2'])`).

Note that performance-wise, you should try these methods of parsing dates in order:

1. Try to infer the format using `infer_datetime_format=True` (see section below).
2. If you know the format, use `pd.to_datetime(): date_parser=lambda x: pd.to_datetime(x, format=...)`.
3. If you have a really non-standard format, use a custom `date_parser` function. For optimal performance, this should be vectorized, i.e., it should accept arrays as arguments.

Parsing a CSV with mixed timezones

pandas cannot natively represent a column or index with mixed timezones. If your CSV file contains columns with a mixture of timezones, the default result will be an object-dtype column with strings, even with `parse_dates`.

```
In [117]: content = """\
.....: a
.....: 2000-01-01T00:00:00+05:00
.....: 2000-01-01T00:00:00+06:00"""
.....:

In [118]: df = pd.read_csv(StringIO(content), parse_dates=["a"])

In [119]: df["a"]
Out[119]:
0    2000-01-01 00:00:00+05:00
1    2000-01-01 00:00:00+06:00
Name: a, dtype: object
```

To parse the mixed-timezone values as a datetime column, pass a partially-applied `to_datetime()` with `utc=True` as the `date_parser`.

```
In [120]: df = pd.read_csv(
.....:     StringIO(content),
.....:     parse_dates=["a"],
.....:     date_parser=lambda col: pd.to_datetime(col, utc=True),
.....: )
.....:

In [121]: df["a"]
Out[121]:
0    1999-12-31 19:00:00+00:00
1    1999-12-31 18:00:00+00:00
Name: a, dtype: datetime64[ns, UTC]
```

Inferring datetime format

If you have `parse_dates` enabled for some or all of your columns, and your datetime strings are all formatted the same way, you may get a large speed up by setting `infer_datetime_format=True`. If set, pandas will attempt to guess the format of your datetime strings, and then use a faster means of parsing the strings. 5-10x parsing speeds have been observed. pandas will fallback to the usual parsing if either the format cannot be guessed or the format that was guessed cannot properly parse the entire column of strings. So in general, `infer_datetime_format` should not have any negative consequences if enabled.

Here are some examples of datetime strings that can be guessed (All representing December 30th, 2011 at 00:00:00):

- “20111230”
- “2011/12/30”
- “20111230 00:00:00”
- “12/30/2011 00:00:00”
- “30/Dec/2011 00:00:00”
- “30/December/2011 00:00:00”

Note that `infer_datetime_format` is sensitive to `dayfirst=True`. With `dayfirst=True`, it will guess “01/12/2011” to be December 1st. With `dayfirst=False` (default) it will guess “01/12/2011” to be January 12th.

```
# Try to infer the format for the index column
In [122]: df = pd.read_csv(
.....:     "foo.csv",
.....:     index_col=0,
.....:     parse_dates=True,
.....:     infer_datetime_format=True,
.....: )
.....:

In [123]: df
Out[123]:
      A   B   C
date
2009-01-01  a   1   2
```

(continues on next page)

(continued from previous page)

2009-01-02	b	3	4
2009-01-03	c	4	5

International date formats

While US date formats tend to be MM/DD/YYYY, many international formats use DD/MM/YYYY instead. For convenience, a `dayfirst` keyword is provided:

```
In [124]: print(open("tmp.csv").read())
date,value,cat
1/6/2000,5,a
2/6/2000,10,b
3/6/2000,15,c

In [125]: pd.read_csv("tmp.csv", parse_dates=[0])
Out[125]:
      date  value  cat
0 2000-01-06      5    a
1 2000-02-06     10    b
2 2000-03-06     15    c

In [126]: pd.read_csv("tmp.csv", dayfirst=True, parse_dates=[0])
Out[126]:
      date  value  cat
0 2000-06-01      5    a
1 2000-06-02     10    b
2 2000-06-03     15    c
```

Writing CSVs to binary file objects

New in version 1.2.0.

`df.to_csv(..., mode="wb")` allows writing a CSV to a file object opened binary mode. In most cases, it is not necessary to specify `mode` as Pandas will auto-detect whether the file object is opened in text or binary mode.

```
In [127]: import io

In [128]: data = pd.DataFrame([0, 1, 2])

In [129]: buffer = io.BytesIO()

In [130]: data.to_csv(buffer, encoding="utf-8", compression="gzip")
```

Specifying method for floating-point conversion

The parameter `float_precision` can be specified in order to use a specific floating-point converter during parsing with the C engine. The options are the ordinary converter, the high-precision converter, and the round-trip converter (which is guaranteed to round-trip values after writing to a file). For example:

```
In [131]: val = "0.3066101993807095471566981359501369297504425048828125"

In [132]: data = "a,b,c\n1,2,{0}".format(val)

In [133]: abs(
.....:     pd.read_csv(
.....:         StringIO(data),
.....:         engine="c",
.....:         float_precision=None,
.....:     )["c"][0] - float(val)
.....: )
.....:

Out[133]: 5.551115123125783e-17

In [134]: abs(
.....:     pd.read_csv(
.....:         StringIO(data),
.....:         engine="c",
.....:         float_precision="high",
.....:     )["c"][0] - float(val)
.....: )
.....:

Out[134]: 5.551115123125783e-17

In [135]: abs(
.....:     pd.read_csv(StringIO(data), engine="c", float_precision="round_trip")["c"
.....:     ][0]
.....:     - float(val)
.....: )
.....:

Out[135]: 0.0
```

Thousand separators

For large numbers that have been written with a thousands separator, you can set the `thousands` keyword to a string of length 1 so that integers will be parsed correctly:

By default, numbers with a thousands separator will be parsed as strings:

```
In [136]: print(open("tmp.csv").read())
ID|level|category
Patient1|123,000|x
Patient2|23,000|y
Patient3|1,234,018|z

In [137]: df = pd.read_csv("tmp.csv", sep="|")
```

(continues on next page)

(continued from previous page)

```
In [138]: df
Out[138]:
      ID      level category
0  Patient1    123,000      x
1  Patient2     23,000      y
2  Patient3   1,234,018      z
```

```
In [139]: df.level.dtype
Out[139]: dtype('O')
```

The thousands keyword allows integers to be parsed correctly:

```
In [140]: print(open("tmp.csv").read())
ID|level|category
Patient1|123,000|x
Patient2|23,000|y
Patient3|1,234,018|z

In [141]: df = pd.read_csv("tmp.csv", sep="|", thousands=",")

In [142]: df
Out[142]:
      ID      level category
0  Patient1    123000      x
1  Patient2     23000      y
2  Patient3   1234018      z

In [143]: df.level.dtype
Out[143]: dtype('int64')
```

NA values

To control which values are parsed as missing values (which are signified by NaN), specify a string in `na_values`. If you specify a list of strings, then all values in it are considered to be missing values. If you specify a number (a float, like 5.0 or an integer like 5), the corresponding equivalent values will also imply a missing value (in this case effectively [5.0, 5] are recognized as NaN).

To completely override the default values that are recognized as missing, specify `keep_default_na=False`.

The default NaN recognized values are `['-1.#IND', '1.#QNAN', '1.#IND', '-1.#QNAN', '#N/A N/A', '#N/A', 'N/A', 'n/a', 'NA', '<NA>', '#NA', 'NULL', 'null', 'NaN', '-NaN', 'nan', '-nan', '']`.

Let us consider some examples:

```
pd.read_csv("path_to_file.csv", na_values=[5])
```

In the example above 5 and 5.0 will be recognized as NaN, in addition to the defaults. A string will first be interpreted as a numerical 5, then as a NaN.

```
pd.read_csv("path_to_file.csv", keep_default_na=False, na_values=[""])
```

Above, only an empty field will be recognized as NaN.

```
pd.read_csv("path_to_file.csv", keep_default_na=False, na_values=["NA", "0"])
```

Above, both NA and 0 as strings are NaN.

```
pd.read_csv("path_to_file.csv", na_values=["Nope"])
```

The default values, in addition to the string "Nope" are recognized as NaN.

Infinity

inf like values will be parsed as np.inf (positive infinity), and -inf as -np.inf (negative infinity). These will ignore the case of the value, meaning Inf, will also be parsed as np.inf.

Returning Series

Using the squeeze keyword, the parser will return output with a single column as a Series:

Deprecated since version 1.4.0: Users should append .squeeze("columns") to the DataFrame returned by read_csv instead.

```
In [144]: print(open("tmp.csv").read())
level
Patient1,123000
Patient2,23000
Patient3,1234018

In [145]: output = pd.read_csv("tmp.csv", squeeze=True)

In [146]: output
Out[146]:
Patient1      123000
Patient2      23000
Patient3      1234018
Name: level, dtype: int64

In [147]: type(output)
Out[147]: pandas.core.series.Series
```

Boolean values

The common values True, False, TRUE, and FALSE are all recognized as boolean. Occasionally you might want to recognize other values as being boolean. To do this, use the true_values and false_values options as follows:

```
In [148]: data = "a,b,c\n1,Yes,2\n3,No,4"

In [149]: print(data)
a,b,c
1,Yes,2
3,No,4

In [150]: pd.read_csv(StringIO(data))
```

(continues on next page)

(continued from previous page)

Out[150]:

```
a    b    c
0  1  Yes  2
1  3   No  4
```

In [151]: pd.read_csv(StringIO(data), true_values=["Yes"], false_values=["No"])**Out[151]:**

```
a    b    c
0  1  True  2
1  3 False  4
```

Handling “bad” lines

Some files may have malformed lines with too few fields or too many. Lines with too few fields will have NA values filled in the trailing fields. Lines with too many fields will raise an error by default:

In [152]: data = "a,b,c\n1,2,3\n4,5,6,7\n8,9,10"**In [153]:** pd.read_csv(StringIO(data))

```

File /pandas/pandas/_libs/parsers.pyx:1960, in pandas._libs.parsers.raise_parser_error()

ParserError: Error tokenizing data. C error: Expected 3 fields in line 3, saw 4

```

You can elect to skip bad lines:

```
In [29]: pd.read_csv(StringIO(data), on_bad_lines="warn")
Skipping line 3: expected 3 fields, saw 4
```

Out[29]:

```
a   b   c
0   1   2   3
1   8   9   10
```

Or pass a callable function to handle the bad line if `engine="python"`. The bad line will be a list of strings that was split by the `sep`:

```
In [29]: external_list = []

In [30]: def bad_lines_func(line):
....:     external_list.append(line)
....:     return line[-3:]
```

(continues on next page)

(continued from previous page)

```
In [31]: pd.read_csv(StringIO(data), on_bad_lines=bad_lines_func, engine="python")
Out[31]:
   a   b   c
0  1   2   3
1  5   6   7
2  8   9  10

In [32]: external_list
Out[32]: [4, 5, 6, 7]

.. versionadded:: 1.4.0
```

You can also use the `usecols` parameter to eliminate extraneous column data that appear in some lines but not others:

```
In [33]: pd.read_csv(StringIO(data), usecols=[0, 1, 2])
Out[33]:
   a   b   c
0  1   2   3
1  4   5   6
2  8   9  10
```

In case you want to keep all data including the lines with too many fields, you can specify a sufficient number of `names`. This ensures that lines with not enough fields are filled with `NaN`.

```
In [34]: pd.read_csv(StringIO(data), names=['a', 'b', 'c', 'd'])
Out[34]:
   a   b   c   d
0  1   2   3   NaN
1  4   5   6   7
2  8   9  10   NaN
```

Dialect

The `dialect` keyword gives greater flexibility in specifying the file format. By default it uses the Excel dialect but you can specify either the dialect name or a `csv.Dialect` instance.

Suppose you had data with unenclosed quotes:

```
In [154]: print(data)
label1,label2,label3
index1,"a,c,e
index2,b,d,f
```

By default, `read_csv` uses the Excel dialect and treats the double quote as the quote character, which causes it to fail when it finds a newline before it finds the closing double quote.

We can get around this using `dialect`:

```
In [155]: import csv
```

(continues on next page)

(continued from previous page)

```
In [156]: dia = csv.excel()

In [157]: dia.quoting = csv.QUOTE_NONE

In [158]: pd.read_csv(StringIO(data), dialect=dia)
Out[158]:
   label1  label2  label3
index1      "a        c        e
index2          b        d        f
```

All of the dialect options can be specified separately by keyword arguments:

```
In [159]: data = "a,b,c~1,2,3~4,5,6"

In [160]: pd.read_csv(StringIO(data), lineterminator="~")
Out[160]:
   a  b  c
0  1  2  3
1  4  5  6
```

Another common dialect option is `skipinitialspace`, to skip any whitespace after a delimiter:

```
In [161]: data = "a, b, c\n1, 2, 3\n4, 5, 6"

In [162]: print(data)
a, b, c
1, 2, 3
4, 5, 6

In [163]: pd.read_csv(StringIO(data), skipinitialspace=True)
Out[163]:
   a  b  c
0  1  2  3
1  4  5  6
```

The parsers make every attempt to “do the right thing” and not be fragile. Type inference is a pretty big deal. If a column can be coerced to integer dtype without altering the contents, the parser will do so. Any non-numeric columns will come through as object dtype as with the rest of pandas objects.

Quoting and Escape Characters

Quotes (and other escape characters) in embedded fields can be handled in any number of ways. One way is to use backslashes; to properly parse this data, you should pass the `escapechar` option:

```
In [164]: data = 'a,b\n"hello, \\\"Bob\\\"", nice to see you",5'

In [165]: print(data)
a,b
"hello, \"Bob\"", nice to see you",5

In [166]: pd.read_csv(StringIO(data), escapechar="\\")
```

Out[166]:

(continues on next page)

(continued from previous page)

	a	b
0	hello, "Bob", nice to see you	5

Files with fixed width columns

While `read_csv()` reads delimited data, the `read_fwf()` function works with data files that have known and fixed column widths. The function parameters to `read_fwf` are largely the same as `read_csv` with two extra parameters, and a different usage of the `delimiter` parameter:

- `colspeсs`: A list of pairs (tuples) giving the extents of the fixed-width fields of each line as half-open intervals (i.e., [from, to[). String value ‘infer’ can be used to instruct the parser to try detecting the column specifications from the first 100 rows of the data. Default behavior, if not specified, is to infer.
- `widths`: A list of field widths which can be used instead of ‘colspeсs’ if the intervals are contiguous.
- `delimiter`: Characters to consider as filler characters in the fixed-width file. Can be used to specify the filler character of the fields if it is not spaces (e.g., ‘~’).

Consider a typical fixed-width data file:

```
In [167]: print(open("bar.csv").read())
id8141    360.242940    149.910199    11950.7
id1594    444.953632    166.985655    11788.4
id1849    364.136849    183.628767    11806.2
id1230    413.836124    184.375703    11916.8
id1948    502.953953    173.237159    12468.3
```

In order to parse this file into a DataFrame, we simply need to supply the column specifications to the `read_fwf` function along with the file name:

```
# Column specifications are a list of half-intervals
In [168]: colspeсs = [(0, 6), (8, 20), (21, 33), (34, 43)]

In [169]: df = pd.read_fwf("bar.csv", colspeсs=colspeсs, header=None, index_col=0)

In [170]: df
Out[170]:
          1          2          3
0
id8141  360.242940  149.910199  11950.7
id1594  444.953632  166.985655  11788.4
id1849  364.136849  183.628767  11806.2
id1230  413.836124  184.375703  11916.8
id1948  502.953953  173.237159  12468.3
```

Note how the parser automatically picks column names X.<column number> when `header=None` argument is specified. Alternatively, you can supply just the column widths for contiguous columns:

```
# Widths are a list of integers
In [171]: widths = [6, 14, 13, 10]

In [172]: df = pd.read_fwf("bar.csv", widths=widths, header=None)
```

(continues on next page)

(continued from previous page)

```
In [173]: df
Out[173]:
   0      1      2      3
0 id8141 360.242940 149.910199 11950.7
1 id1594 444.953632 166.985655 11788.4
2 id1849 364.136849 183.628767 11806.2
3 id1230 413.836124 184.375703 11916.8
4 id1948 502.953953 173.237159 12468.3
```

The parser will take care of extra white spaces around the columns so it's ok to have extra separation between the columns in the file.

By default, `read_fwf` will try to infer the file's `cols` by using the first 100 rows of the file. It can do it only in cases when the columns are aligned and correctly separated by the provided `delimiter` (default delimiter is whitespace).

```
In [174]: df = pd.read_fwf("bar.csv", header=None, index_col=0)
```

```
In [175]: df
Out[175]:
   1      2      3
0
id8141 360.242940 149.910199 11950.7
id1594 444.953632 166.985655 11788.4
id1849 364.136849 183.628767 11806.2
id1230 413.836124 184.375703 11916.8
id1948 502.953953 173.237159 12468.3
```

`read_fwf` supports the `dtype` parameter for specifying the types of parsed columns to be different from the inferred type.

```
In [176]: pd.read_fwf("bar.csv", header=None, index_col=0).dtypes
```

```
Out[176]:
0    float64
1    float64
2    float64
3    float64
dtype: object
```

```
In [177]: pd.read_fwf("bar.csv", header=None, dtype={2: "object"}).dtypes
```

```
Out[177]:
0    object
1    float64
2    object
3    float64
dtype: object
```

Indexes

Files with an “implicit” index column

Consider a file with one less entry in the header than the number of data column:

```
In [178]: print(open("foo.csv").read())
A,B,C
20090101,a,1,2
20090102,b,3,4
20090103,c,4,5
```

In this special case, `read_csv` assumes that the first column is to be used as the index of the DataFrame:

```
In [179]: pd.read_csv("foo.csv")
Out[179]:
   A   B   C
20090101  a   1   2
20090102  b   3   4
20090103  c   4   5
```

Note that the dates weren't automatically parsed. In that case you would need to do as before:

```
In [180]: df = pd.read_csv("foo.csv", parse_dates=True)

In [181]: df.index
Out[181]: DatetimeIndex(['2009-01-01', '2009-01-02', '2009-01-03'], dtype='datetime64[ns']
                         ', freq=None)
```

Reading an index with a MultiIndex

Suppose you have data indexed by two columns:

```
In [182]: print(open("data/mindex_ex.csv").read())
year,indiv,zit,xit
1977,"A",1.2,.6
1977,"B",1.5,.5
1977,"C",1.7,.8
1978,"A",.2,.06
1978,"B",.7,.2
1978,"C",.8,.3
1978,"D",.9,.5
1978,"E",1.4,.9
1979,"C",.2,.15
1979,"D",.14,.05
1979,"E",.5,.15
1979,"F",1.2,.5
1979,"G",3.4,1.9
1979,"H",5.4,2.7
1979,"I",6.4,1.2
```

The `index_col` argument to `read_csv` can take a list of column numbers to turn multiple columns into a `MultiIndex` for the index of the returned object:

```
In [183]: df = pd.read_csv("data/mindex_ex.csv", index_col=[0, 1])
```

```
In [184]: df
```

```
Out[184]:
```

```
      zit    xit  
year indiv  
1977 A     1.20  0.60  
      B     1.50  0.50  
      C     1.70  0.80  
1978 A     0.20  0.06  
      B     0.70  0.20  
      C     0.80  0.30  
      D     0.90  0.50  
      E     1.40  0.90  
1979 C     0.20  0.15  
      D     0.14  0.05  
      E     0.50  0.15  
      F     1.20  0.50  
      G     3.40  1.90  
      H     5.40  2.70  
      I     6.40  1.20
```

```
In [185]: df.loc[1978]
```

```
Out[185]:
```

```
      zit    xit  
indiv  
A     0.2  0.06  
B     0.7  0.20  
C     0.8  0.30  
D     0.9  0.50  
E     1.4  0.90
```

Reading columns with a MultiIndex

By specifying list of row locations for the `header` argument, you can read in a `MultiIndex` for the columns. Specifying non-consecutive rows will skip the intervening rows.

```
In [186]: from pandas._testing import makeCustomDataframe as mkdf
```

```
In [187]: df = mkdf(5, 3, r_idx_nlevels=2, c_idx_nlevels=4)
```

```
In [188]: df.to_csv("mi.csv")
```

```
In [189]: print(open("mi.csv").read())
```

```
C0,,C_10_g0,C_10_g1,C_10_g2  
C1,,C_11_g0,C_11_g1,C_11_g2  
C2,,C_12_g0,C_12_g1,C_12_g2  
C3,,C_13_g0,C_13_g1,C_13_g2  
R0,R1,,,  
R_10_g0,R_11_g0,R0C0,R0C1,R0C2  
R_10_g1,R_11_g1,R1C0,R1C1,R1C2
```

(continues on next page)

(continued from previous page)

```
R_10_g2,R_11_g2,R2C0,R2C1,R2C2
R_10_g3,R_11_g3,R3C0,R3C1,R3C2
R_10_g4,R_11_g4,R4C0,R4C1,R4C2
```

In [190]: pd.read_csv("mi.csv", header=[0, 1, 2, 3], index_col=[0, 1])
Out[190]:

C0	C_10_g0	C_10_g1	C_10_g2	
C1	C_11_g0	C_11_g1	C_11_g2	
C2	C_12_g0	C_12_g1	C_12_g2	
C3	C_13_g0	C_13_g1	C_13_g2	
R0	R1			
R_10_g0	R_11_g0	R0C0	R0C1	R0C2
R_10_g1	R_11_g1	R1C0	R1C1	R1C2
R_10_g2	R_11_g2	R2C0	R2C1	R2C2
R_10_g3	R_11_g3	R3C0	R3C1	R3C2
R_10_g4	R_11_g4	R4C0	R4C1	R4C2

read_csv is also able to interpret a more common format of multi-columns indices.

In [191]: print(open("mi2.csv").read())

```
,a,a,a,b,c
,q,r,s,t,u,v
one,1,2,3,4,5,6
two,7,8,9,10,11,12
```

In [192]: pd.read_csv("mi2.csv", header=[0, 1], index_col=0)
Out[192]:

a	b	c				
q	r	s	t	u	v	
one	1	2	3	4	5	6
two	7	8	9	10	11	12

Note: If an `index_col` is not specified (e.g. you don't have an index, or wrote it with `df.to_csv(..., index=False)`), then any `names` on the columns index will be *lost*.

Automatically “sniffing” the delimiter

`read_csv` is capable of inferring delimited (not necessarily comma-separated) files, as pandas uses the `csv.Sniffer` class of the `csv` module. For this, you have to specify `sep=None`.

In [193]: print(open("tmp2.csv").read())

```

Reading multiple files to create a single DataFrame

It's best to use `concat()` to combine multiple files. See the *cookbook* for an example.

Iterating through files chunk by chunk

Suppose you wish to iterate through a (potentially very large) file lazily rather than reading the entire file into memory, such as the following:

```
In [195]: print(open("tmp.csv").read())
|0|1|2|3
0|0.4691122999071863|-0.2828633443286633|-1.5090585031735124|-1.1356323710171934
1|1.2121120250208506|-0.17321464905330858|0.11920871129693428|-1.0442359662799567
2| -0.8618489633477999|-2.1045692188948086|-0.4949292740687813|1.071803807037338
3| 0.7215551622443669|-0.7067711336300845|-1.0395749851146963|0.27185988554282986
4| -0.42497232978883753|0.567020349793672|0.27623201927771873|-1.0874006912859915
5| -0.6736897080883706|0.1136484096888855|-1.4784265524372235|0.5249876671147047
6| 0.4047052186802365|0.5770459859204836|-1.7150020161146375|-1.0392684835147725

(continues on next page)

(continued from previous page)

5	5	-0.673690	0.113648	-1.478427	0.524988
6	6	0.404705	0.577046	-1.715002	-1.039268
7	7	-0.370647	-1.157892	-1.344312	0.844885
8	8	1.075770	-0.109050	1.643563	-1.469388
9	9	0.357021	-0.674600	-1.776904	-0.968914

By specifying a `chunksize` to `read_csv`, the return value will be an iterable object of type `TextFileReader`:

```
In [198]: with pd.read_csv("tmp.csv", sep="|", chunksize=4) as reader:
    ....:     reader
    ....:     for chunk in reader:
    ....:         print(chunk)
    ....:
    Unnamed: 0      0      1      2      3
0      0  0.469112 -0.282863 -1.509059 -1.135632
1      1  1.212112 -0.173215  0.119209 -1.044236
2      2 -0.861849 -2.104569 -0.494929  1.071804
3      3  0.721555 -0.706771 -1.039575  0.271860
    Unnamed: 0      0      1      2      3
4      4 -0.424972  0.567020  0.276232 -1.087401
5      5 -0.673690  0.113648 -1.478427  0.524988
6      6  0.404705  0.577046 -1.715002 -1.039268
7      7 -0.370647 -1.157892 -1.344312  0.844885
    Unnamed: 0      0      1      2      3
8      8  1.075770 -0.109050  1.643563 -1.469388
9      9  0.357021 -0.674600 -1.776904 -0.968914
```

Changed in version 1.2: `read_csv/json/sas` return a context-manager when iterating through a file.

Specifying `iterator=True` will also return the `TextFileReader` object:

```
In [199]: with pd.read_csv("tmp.csv", sep="|", iterator=True) as reader:
    ....:     reader.get_chunk(5)
    ....:
```

Specifying the parser engine

Pandas currently supports three engines, the C engine, the python engine, and an experimental pyarrow engine (requires the `pyarrow` package). In general, the pyarrow engine is fastest on larger workloads and is equivalent in speed to the C engine on most other workloads. The python engine tends to be slower than the pyarrow and C engines on most workloads. However, the pyarrow engine is much less robust than the C engine, which lacks a few features compared to the Python engine.

Where possible, pandas uses the C parser (specified as `engine='c'`), but it may fall back to Python if C-unsupported options are specified.

Currently, options unsupported by the C and pyarrow engines include:

- `sep` other than a single character (e.g. regex separators)
- `skipfooter`
- `sep=None` with `delim_whitespace=False`

Specifying any of the above options will produce a `ParserWarning` unless the python engine is selected explicitly using `engine='python'`.

Options that are unsupported by the pyarrow engine which are not covered by the list above include:

- `float_precision`
- `chunksize`
- `comment`
- `nrows`
- `thousands`
- `memory_map`
- `dialect`
- `warn_bad_lines`
- `error_bad_lines`
- `on_bad_lines`
- `delim_whitespace`
- `quoting`
- `lineterminator`
- `converters`
- `decimal`
- `iterator`
- `dayfirst`
- `infer_datetime_format`
- `verbose`
- `skipinitialspace`
- `low_memory`

Specifying these options with `engine='pyarrow'` will raise a `ValueError`.

Reading/writing remote files

You can pass in a URL to read or write remote files to many of pandas' IO functions - the following example shows reading a CSV file:

```
df = pd.read_csv("https://download.bls.gov/pub/time.series/cu/cu.item", sep="\t")
```

New in version 1.3.0.

A custom header can be sent alongside HTTP(s) requests by passing a dictionary of header key value mappings to the `storage_options` keyword argument as shown below:

```
headers = {"User-Agent": "pandas"}  
df = pd.read_csv(  
    "https://download.bls.gov/pub/time.series/cu/cu.item",  
    sep="\t",
```

(continues on next page)

(continued from previous page)

```
storage_options=headers
)
```

All URLs which are not local files or HTTP(s) are handled by `fsspec`, if installed, and its various filesystem implementations (including Amazon S3, Google Cloud, SSH, FTP, webHDFS...). Some of these implementations will require additional packages to be installed, for example S3 URLs require the `s3fs` library:

```
df = pd.read_json("s3://pandas-test/adatafile.json")
```

When dealing with remote storage systems, you might need extra configuration with environment variables or config files in special locations. For example, to access data in your S3 bucket, you will need to define credentials in one of the several ways listed in the [S3Fs documentation](#). The same is true for several of the storage backends, and you should follow the links at `fsimpl1` for implementations built into `fsspec` and `fsimpl2` for those not included in the main `fsspec` distribution.

You can also pass parameters directly to the backend driver. For example, if you do *not* have S3 credentials, you can still access public data by specifying an anonymous connection, such as

New in version 1.2.0.

```
pd.read_csv(
    "s3://ncei-wcsd-archive/data/processed/SH1305/18kHz/SaKe2013"
    "-D20130523-T080854_to_SaKe2013-D20130523-T085643.csv",
    storage_options={"anon": True},
)
```

`fsspec` also allows complex URLs, for accessing data in compressed archives, local caching of files, and more. To locally cache the above example, you would modify the call to

```
pd.read_csv(
    "simplecache::s3://ncei-wcsd-archive/data/processed/SH1305/18kHz/"
    "SaKe2013-D20130523-T080854_to_SaKe2013-D20130523-T085643.csv",
    storage_options={"s3": {"anon": True}},
)
```

where we specify that the “anon” parameter is meant for the “s3” part of the implementation, not to the caching implementation. Note that this caches to a temporary directory for the duration of the session only, but you can also specify a permanent store.

Writing out data

Writing to CSV format

The `Series` and `DataFrame` objects have an instance method `to_csv` which allows storing the contents of the object as a comma-separated-values file. The function takes a number of arguments. Only the first is required.

- `path_or_buf`: A string path to the file to write or a file object. If a file object it must be opened with `newline=''`
- `sep` : Field delimiter for the output file (default “,”)
- `na_rep`: A string representation of a missing value (default “ ”)
- `float_format`: Format string for floating point numbers
- `columns`: Columns to write (default None)

- `header`: Whether to write out the column names (default True)
- `index`: whether to write row (index) names (default True)
- `index_label`: Column label(s) for index column(s) if desired. If None (default), and `header` and `index` are True, then the index names are used. (A sequence should be given if the DataFrame uses MultiIndex).
- `mode` : Python write mode, default ‘w’
- `encoding`: a string representing the encoding to use if the contents are non-ASCII, for Python versions prior to 3
- `line_terminator`: Character sequence denoting line end (default `os.linesep`)
- `quoting`: Set quoting rules as in csv module (default `csv.QUOTE_MINIMAL`). Note that if you have set a `float_format` then floats are converted to strings and `csv.QUOTE_NONNUMERIC` will treat them as non-numeric
- `quotechar`: Character used to quote fields (default “””)
- `doublequote`: Control quoting of `quotechar` in fields (default True)
- `escapechar`: Character used to escape `sep` and `quotechar` when appropriate (default None)
- `chunksize`: Number of rows to write at a time
- `date_format`: Format string for datetime objects

Writing a formatted string

The DataFrame object has an instance method `to_string` which allows control over the string representation of the object. All arguments are optional:

- `buf` default None, for example a `StringIO` object
- `columns` default None, which columns to write
- `col_space` default None, minimum width of each column.
- `na_rep` default `NaN`, representation of NA value
- `formatters` default None, a dictionary (by column) of functions each of which takes a single argument and returns a formatted string
- `float_format` default None, a function which takes a single (float) argument and returns a formatted string; to be applied to floats in the DataFrame.
- `sparsify` default True, set to False for a DataFrame with a hierarchical index to print every MultiIndex key at each row.
- `index_names` default True, will print the names of the indices
- `index` default True, will print the index (ie, row labels)
- `header` default True, will print the column labels
- `justify` default `left`, will print column headers left- or right-justified

The Series object also has a `to_string` method, but with only the `buf`, `na_rep`, `float_format` arguments. There is also a `length` argument which, if set to True, will additionally output the length of the Series.

2.4.2 JSON

Read and write JSON format files and strings.

Writing JSON

A Series or DataFrame can be converted to a valid JSON string. Use `to_json` with optional parameters:

- `path_or_buf` : the pathname or buffer to write the output This can be `None` in which case a JSON string is returned

- `orient` :

Series:

- default is `index`
- allowed values are `{split, records, index}`

DataFrame:

- default is `columns`
- allowed values are `{split, records, index, columns, values, table}`

The format of the JSON string

<code>split</code>	dict like {index -> [index], columns -> [columns], data -> [values]}
<code>records</code>	list like [{column -> value}, ... , {column -> value}]
<code>index</code>	dict like {index -> {column -> value}}
<code>columns</code>	dict like {column -> {index -> value}}
<code>values</code>	just the values array
<code>table</code>	adhering to the JSON Table Schema

- `date_format` : string, type of date conversion, ‘epoch’ for timestamp, ‘iso’ for ISO8601.
- `double_precision` : The number of decimal places to use when encoding floating point values, default 10.
- `force_ascii` : force encoded string to be ASCII, default True.
- `date_unit` : The time unit to encode to, governs timestamp and ISO8601 precision. One of ‘s’, ‘ms’, ‘us’ or ‘ns’ for seconds, milliseconds, microseconds and nanoseconds respectively. Default ‘ms’.
- `default_handler` : The handler to call if an object cannot otherwise be converted to a suitable format for JSON. Takes a single argument, which is the object to convert, and returns a serializable object.
- `lines` : If `records` orient, then will write each record per line as json.

Note `Nan`'s, `NaT`'s and `None` will be converted to `null` and `datetime` objects will be converted based on the `date_format` and `date_unit` parameters.

```
In [200]: dfj = pd.DataFrame(np.random.randn(5, 2), columns=list("AB"))
```

```
In [201]: json = dfj.to_json()
```

```
In [202]: json
```

```
Out[202]: '{"A":{"0": -1.2945235903, "1": 0.2766617129, "2": -0.0139597524, "3": -0.0061535699, "4": 0.8957173022}, "B": {"0": 0.4137381054, "1": -0.472034511, "2": -0.3625429925, "3": -0.923060654, "4": 0.8052440254}}'
```

Orient options

There are a number of different options for the format of the resulting JSON file / string. Consider the following DataFrame and Series:

```
In [203]: dfjo = pd.DataFrame(  
.....:     dict(A=range(1, 4), B=range(4, 7), C=range(7, 10)),  
.....:     columns=list("ABC"),  
.....:     index=list("xyz"),  
.....: )  
.....:  
  
In [204]: dfjo  
Out[204]:  
   A   B   C  
x  1   4   7  
y  2   5   8  
z  3   6   9  
  
In [205]: sjo = pd.Series(dict(x=15, y=16, z=17), name="D")  
  
In [206]: sjo  
Out[206]:  
x    15  
y    16  
z    17  
Name: D, dtype: int64
```

Column oriented (the default for DataFrame) serializes the data as nested JSON objects with column labels acting as the primary index:

```
In [207]: dfjo.to_json(orient="columns")  
Out[207]: '{"A":{"x":1,"y":2,"z":3}, "B":{"x":4,"y":5,"z":6}, "C":{"x":7,"y":8,"z":9}}'  
  
# Not available for Series
```

Index oriented (the default for Series) similar to column oriented but the index labels are now primary:

```
In [208]: dfjo.to_json(orient="index")  
Out[208]: '{"x":{"A":1,"B":4,"C":7}, "y":{"A":2,"B":5,"C":8}, "z":{"A":3,"B":6,"C":9}}'  
  
In [209]: sjo.to_json(orient="index")  
Out[209]: '{"x":15, "y":16, "z":17}'
```

Record oriented serializes the data to a JSON array of column -> value records, index labels are not included. This is useful for passing DataFrame data to plotting libraries, for example the JavaScript library d3.js:

```
In [210]: dfjo.to_json(orient="records")  
Out[210]: '[{"A":1,"B":4,"C":7}, {"A":2,"B":5,"C":8}, {"A":3,"B":6,"C":9}]'  
  
In [211]: sjo.to_json(orient="records")  
Out[211]: '[15, 16, 17]'
```

Value oriented is a bare-bones option which serializes to nested JSON arrays of values only, column and index labels are not included:

```
In [212]: dfjo.to_json(orient="values")
Out[212]: '[[1,4,7],[2,5,8],[3,6,9]]'

# Not available for Series
```

Split oriented serializes to a JSON object containing separate entries for values, index and columns. Name is also included for Series:

```
In [213]: dfjo.to_json(orient="split")
Out[213]: {"columns": ["A", "B", "C"], "index": ["x", "y", "z"], "data": [[1, 4, 7], [2, 5, 8], [3, 6, 9]]}

In [214]: sjo.to_json(orient="split")
Out[214]: {"name": "D", "index": ["x", "y", "z"], "data": [15, 16, 17]}
```

Table oriented serializes to the JSON Table Schema, allowing for the preservation of metadata including but not limited to dtypes and index names.

Note: Any orient option that encodes to a JSON object will not preserve the ordering of index and column labels during round-trip serialization. If you wish to preserve label ordering use the `split` option as it uses ordered containers.

Date handling

Writing in ISO date format:

```
In [215]: dfd = pd.DataFrame(np.random.randn(5, 2), columns=list("AB"))

In [216]: dfd["date"] = pd.Timestamp("20130101")

In [217]: dfd = dfd.sort_index(axis=1, ascending=False)

In [218]: json = dfd.to_json(date_format="iso")

In [219]: json
Out[219]: {"date": {"0": "2013-01-01T00:00:00.000Z", "1": "2013-01-01T00:00:00.000Z", "2": "2013-01-01T00:00:00.000Z", "3": "2013-01-01T00:00:00.000Z", "4": "2013-01-01T00:00:00.000Z"}, "B": {"0": 2.5656459463, "1": 1.3403088498, "2": -0.2261692849, "3": 0.8138502857, "4": -0.8273169356}, "A": {"0": -1.2064117817, "1": 1.4312559863, "2": -1.1702987971, "3": 0.4108345112, "4": 0.1320031703}}
```

Writing in ISO date format, with microseconds:

```
In [220]: json = dfd.to_json(date_format="iso", date_unit="us")

In [221]: json
Out[221]: {"date": {"0": "2013-01-01T00:00:00.000000Z", "1": "2013-01-01T00:00:00.000000Z", "2": "2013-01-01T00:00:00.000000Z", "3": "2013-01-01T00:00:00.000000Z", "4": "2013-01-01T00:00:00.000000Z"}, "B": {"0": 2.5656459463, "1": 1.3403088498, "2": -0.2261692849, "3": 0.8138502857, "4": -0.8273169356}, "A": {"0": -1.2064117817, "1": 1.4312559863, "2": -1.1702987971, "3": 0.4108345112, "4": 0.1320031703}}
```

Epoch timestamps, in seconds:

```
In [222]: json = dfd.to_json(date_format="epoch", date_unit="s")
```

```
In [223]: json
```

```
Out[223]: '{"date": {"0": 1356998400, "1": 1356998400, "2": 1356998400, "3": 1356998400, "4": -1356998400}, "B": {"0": 2.5656459463, "1": 1.3403088498, "2": -0.2261692849, "3": 0.8138502857, "4": -0.8273169356}, "A": {"0": -1.2064117817, "1": 1.4312559863, "2": -1.1702987971, "3": 0.4108345112, "4": 0.1320031703}}'
```

Writing to a file, with a date index and a date column:

```
In [224]: dfj2 = dfj.copy()
```

```
In [225]: dfj2["date"] = pd.Timestamp("20130101")
```

```
In [226]: dfj2["ints"] = list(range(5))
```

```
In [227]: dfj2["bools"] = True
```

```
In [228]: dfj2.index = pd.date_range("20130101", periods=5)
```

```
In [229]: dfj2.to_json("test.json")
```

```
In [230]: with open("test.json") as fh:  
    ....:  
        print(fh.read())  
    ....:  
{"A": {"1356998400000": -1.2945235903, "1357084800000": 0.2766617129, "1357171200000": -0.0139597524, "1357257600000": -0.0061535699, "1357344000000": 0.8957173022}, "B": {"1356998400000": 0.4137381054, "1357084800000": -0.472034511, "1357171200000": -0.3625429925, "1357257600000": -0.923060654, "1357344000000": 0.8052440254}, "date": {"1356998400000": 1356998400000, "1357084800000": 1356998400000, "1357171200000": 1356998400000, "1357257600000": 1356998400000, "1357344000000": 1356998400000}, "ints": {"1356998400000": 0, "1357084800000": 1, "1357171200000": 2, "1357257600000": 3, "1357344000000": 4}, "bools": {"1356998400000": true, "1357084800000": true, "1357171200000": true, "1357257600000": true, "1357344000000": true}}
```

Fallback behavior

If the JSON serializer cannot handle the container contents directly it will fall back in the following manner:

- if the dtype is unsupported (e.g. `np.complex_`) then the `default_handler`, if provided, will be called for each value, otherwise an exception is raised.
- if an object is unsupported it will attempt the following:
 - check if the object has defined a `toDict` method and call it. A `toDict` method should return a `dict` which will then be JSON serialized.
 - invoke the `default_handler` if one was provided.
 - convert the object to a `dict` by traversing its contents. However this will often fail with an `OverflowError` or give unexpected results.

In general the best approach for unsupported objects or dtypes is to provide a `default_handler`. For example:

```
>>> DataFrame([1.0, 2.0, complex(1.0, 2.0)]).to_json() # raises
RuntimeError: Unhandled numpy dtype 15
```

can be dealt with by specifying a simple `default_handler`:

```
In [231]: pd.DataFrame([1.0, 2.0, complex(1.0, 2.0)]).to_json(default_handler=str)
Out[231]: '{"0":{"0":"(1+0j)", "1":"(2+0j)", "2":"(1+2j)"}}'
```

Reading JSON

Reading a JSON string to pandas object can take a number of parameters. The parser will try to parse a `DataFrame` if `typ` is not supplied or is `None`. To explicitly force `Series` parsing, pass `typ=series`

- `filepath_or_buffer` : a **VALID** JSON string or file handle / `StringIO`. The string could be a URL. Valid URL schemes include http, ftp, S3, and file. For file URLs, a host is expected. For instance, a local file could be file `://localhost/path/to/table.json`
- `typ` : type of object to recover (series or frame), default ‘frame’
- `orient` :
- Series :**
 - default is `index`
 - allowed values are {`split`, `records`, `index`}

DataFrame

- default is `columns`
- allowed values are {`split`, `records`, `index`, `columns`, `values`, `table`}

The format of the JSON string

<code>split</code>	dict like { <code>index</code> -> [<code>index</code>], <code>columns</code> -> [<code>columns</code>], <code>data</code> -> [<code>values</code>]}
<code>records</code>	list like [{ <code>column</code> -> <code>value</code> }, ..., { <code>column</code> -> <code>value</code> }]
<code>index</code>	dict like { <code>index</code> -> { <code>column</code> -> <code>value</code> } }
<code>columns</code>	dict like { <code>column</code> -> { <code>index</code> -> <code>value</code> } }
<code>values</code>	just the <code>values</code> array
<code>table</code>	adhering to the JSON Table Schema

- `dtype` : if `True`, infer dtypes, if a dict of column to `dtype`, then use those, if `False`, then don’t infer dtypes at all, default is `True`, apply only to the data.
- `convert_axes` : boolean, try to convert the axes to the proper dtypes, default is `True`
- `convert_dates` : a list of columns to parse for dates; If `True`, then try to parse date-like columns, default is `True`.
- `keep_default_dates` : boolean, default `True`. If parsing dates, then parse the default date-like columns.
- `numpy` : direct decoding to NumPy arrays. default is `False`; Supports numeric data only, although labels may be non-numeric. Also note that the JSON ordering **MUST** be the same for each term if `numpy=True`.
- `precise_float` : boolean, default `False`. Set to enable usage of higher precision (`strtod`) function when decoding string to double values. Default (`False`) is to use fast but less precise builtin functionality.

- `date_unit` : string, the timestamp unit to detect if converting dates. Default None. By default the timestamp precision will be detected, if this is not desired then pass one of ‘s’, ‘ms’, ‘us’ or ‘ns’ to force timestamp precision to seconds, milliseconds, microseconds or nanoseconds respectively.
- `lines` : reads file as one json object per line.
- `encoding` : The encoding to use to decode py3 bytes.
- `chunksize` : when used in combination with `lines=True`, return a JsonReader which reads in `chunksize` lines per iteration.

The parser will raise one of `ValueError`/`TypeError`/`AssertionError` if the JSON is not parseable.

If a non-default `orient` was used when encoding to JSON be sure to pass the same option here so that decoding produces sensible results, see [Orient Options](#) for an overview.

Data conversion

The default of `convert_axes=True`, `dtype=True`, and `convert_dates=True` will try to parse the axes, and all of the data into appropriate types, including dates. If you need to override specific dtypes, pass a dict to `dtype`. `convert_axes` should only be set to `False` if you need to preserve string-like numbers (e.g. ‘1’, ‘2’) in an axes.

Note: Large integer values may be converted to dates if `convert_dates=True` and the data and / or column labels appear ‘date-like’. The exact threshold depends on the `date_unit` specified. ‘date-like’ means that the column label meets one of the following criteria:

- it ends with ‘_at’
 - it ends with ‘_time’
 - it begins with ‘timestamp’
 - it is ‘modified’
 - it is ‘date’
-

Warning: When reading JSON data, automatic coercing into dtypes has some quirks:

- an index can be reconstructed in a different order from serialization, that is, the returned order is not guaranteed to be the same as before serialization
- a column that was `float` data will be converted to `integer` if it can be done safely, e.g. a column of 1.
- bool columns will be converted to `integer` on reconstruction

Thus there are times where you may want to specify specific dtypes via the `dtype` keyword argument.

Reading from a JSON string:

```
In [232]: pd.read_json(json)
Out[232]:
      date          B          A
0 2013-01-01  2.565646 -1.206412
1 2013-01-01  1.340309  1.431256
2 2013-01-01 -0.226169 -1.170299
3 2013-01-01  0.813850  0.410835
4 2013-01-01 -0.827317  0.132003
```

Reading from a file:

```
In [233]: pd.read_json("test.json")
Out[233]:
          A         B      date  ints  bools
2013-01-01 -1.294524  0.413738 2013-01-01    0   True
2013-01-02  0.276662 -0.472035 2013-01-01    1   True
2013-01-03 -0.013960 -0.362543 2013-01-01    2   True
2013-01-04 -0.006154 -0.923061 2013-01-01    3   True
2013-01-05  0.895717  0.805244 2013-01-01    4   True
```

Don't convert any data (but still convert axes and dates):

```
In [234]: pd.read_json("test.json", dtype=object).dtypes
Out[234]:
A        object
B        object
date    object
ints    object
bools   object
dtype: object
```

Specify dtypes for conversion:

```
In [235]: pd.read_json("test.json", dtype={"A": "float32", "bools": "int8"}).dtypes
Out[235]:
A           float32
B           float64
date     datetime64[ns]
ints          int64
bools          int8
dtype: object
```

Preserve string indices:

```
In [236]: si = pd.DataFrame(
.....:     np.zeros((4, 4)), columns=list(range(4)), index=[str(i) for i in range(4)])
.....:
.....:

In [237]: si
Out[237]:
   0   1   2   3
0  0.0  0.0  0.0  0.0
1  0.0  0.0  0.0  0.0
2  0.0  0.0  0.0  0.0
3  0.0  0.0  0.0  0.0

In [238]: si.index
Out[238]: Index(['0', '1', '2', '3'], dtype='object')

In [239]: si.columns
Out[239]: Int64Index([0, 1, 2, 3], dtype='int64')
```

(continues on next page)

(continued from previous page)

```
In [240]: json = si.to_json()

In [241]: sij = pd.read_json(json, convert_axes=False)

In [242]: sij
Out[242]:
   0  1  2  3
0  0  0  0  0
1  0  0  0  0
2  0  0  0  0
3  0  0  0  0

In [243]: sij.index
Out[243]: Index(['0', '1', '2', '3'], dtype='object')

In [244]: sij.columns
Out[244]: Index(['0', '1', '2', '3'], dtype='object')
```

Dates written in nanoseconds need to be read back in nanoseconds:

```
In [245]: json = dfj2.to_json(date_unit="ns")

# Try to parse timestamps as milliseconds -> Won't Work
In [246]: dfju = pd.read_json(json, date_unit="ms")

In [247]: dfju
Out[247]:
          A         B           date  ints  bools
13569984000000000000 -1.294524  0.413738 13569984000000000000     0  True
13570848000000000000  0.276662 -0.472035 13569984000000000000     1  True
13571712000000000000 -0.013960 -0.362543 13569984000000000000     2  True
13572576000000000000 -0.006154 -0.923061 13569984000000000000     3  True
13573440000000000000  0.895717  0.805244 13569984000000000000     4  True

# Let pandas detect the correct precision
In [248]: dfju = pd.read_json(json)

In [249]: dfju
Out[249]:
          A         B           date  ints  bools
2013-01-01 -1.294524  0.413738 2013-01-01     0  True
2013-01-02  0.276662 -0.472035 2013-01-01     1  True
2013-01-03 -0.013960 -0.362543 2013-01-01     2  True
2013-01-04 -0.006154 -0.923061 2013-01-01     3  True
2013-01-05  0.895717  0.805244 2013-01-01     4  True

# Or specify that all timestamps are in nanoseconds
In [250]: dfju = pd.read_json(json, date_unit="ns")

In [251]: dfju
Out[251]:
          A         B           date  ints  bools
```

(continues on next page)

(continued from previous page)

2013-01-01	-1.294524	0.413738	2013-01-01	0	True
2013-01-02	0.276662	-0.472035	2013-01-01	1	True
2013-01-03	-0.013960	-0.362543	2013-01-01	2	True
2013-01-04	-0.006154	-0.923061	2013-01-01	3	True
2013-01-05	0.895717	0.805244	2013-01-01	4	True

The Numpy parameter

Note: This param has been deprecated as of version 1.0.0 and will raise a `FutureWarning`.

This supports numeric data only. Index and columns labels may be non-numeric, e.g. strings, dates etc.

If `numpy=True` is passed to `read_json` an attempt will be made to sniff an appropriate dtype during deserialization and to subsequently decode directly to NumPy arrays, bypassing the need for intermediate Python objects.

This can provide speedups if you are deserialising a large amount of numeric data:

```
In [252]: randfloats = np.random.uniform(-100, 1000, 10000)

In [253]: randfloats.shape = (1000, 10)

In [254]: dffloats = pd.DataFrame(randfloats, columns=list("ABCDEFGHIJ"))

In [255]: jsonfloats = dffloats.to_json()
```

```
In [256]: %timeit pd.read_json(jsonfloats)
10.5 ms +- 848 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

```
In [257]: %timeit pd.read_json(jsonfloats, numpy=True)
6.9 ms +- 216 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

The speedup is less noticeable for smaller datasets:

```
In [258]: jsonfloats = dffloats.head(100).to_json()
```

```
In [259]: %timeit pd.read_json(jsonfloats)
5.51 ms +- 488 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

```
In [260]: %timeit pd.read_json(jsonfloats, numpy=True)
4.82 ms +- 569 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

Warning: Direct NumPy decoding makes a number of assumptions and may fail or produce unexpected output if these assumptions are not satisfied:

- data is numeric.
- data is uniform. The dtype is sniffed from the first value decoded. A `ValueError` may be raised, or incorrect output may be produced if this condition is not satisfied.

- labels are ordered. Labels are only read from the first container, it is assumed that each subsequent row / column has been encoded in the same order. This should be satisfied if the data was encoded using `to_json` but may not be the case if the JSON is from another source.

Normalization

pandas provides a utility function to take a dict or list of dicts and *normalize* this semi-structured data into a flat table.

```
In [261]: data = [
....:     {"id": 1, "name": {"first": "Coleen", "last": "Volk"}},
....:     {"name": {"given": "Mark", "family": "Regner"}},
....:     {"id": 2, "name": "Faye Raker"},
....: ]
....:
```

```
In [262]: pd.json_normalize(data)
```

```
Out[262]:
   id name.first name.last name.given name.family      name
0  1.0      Coleen      Volk        NaN        NaN      NaN
1  NaN        NaN        NaN       Mark      Regner      NaN
2  2.0        NaN        NaN        NaN        NaN  Faye Raker
```

```
In [263]: data = [
....:     {
....:         "state": "Florida",
....:         "shortname": "FL",
....:         "info": {"governor": "Rick Scott"},
....:         "county": [
....:             {"name": "Dade", "population": 12345},
....:             {"name": "Broward", "population": 40000},
....:             {"name": "Palm Beach", "population": 60000},
....:         ],
....:     },
....:     {
....:         "state": "Ohio",
....:         "shortname": "OH",
....:         "info": {"governor": "John Kasich"},
....:         "county": [
....:             {"name": "Summit", "population": 1234},
....:             {"name": "Cuyahoga", "population": 1337},
....:         ],
....:     },
....: ]
....:
```

```
In [264]: pd.json_normalize(data, "county", ["state", "shortname", ["info", "governor"]])
```

```
Out[264]:
      name  population      state shortname info.governor
0      Dade       12345  Florida          FL    Rick Scott
1  Broward       40000  Florida          FL    Rick Scott
2  Palm Beach      60000  Florida          FL    Rick Scott
```

(continues on next page)

(continued from previous page)

3	Summit	1234	Ohio	OH	John Kasich
4	Cuyahoga	1337	Ohio	OH	John Kasich

The `max_level` parameter provides more control over which level to end normalization. With `max_level=1` the following snippet normalizes until 1st nesting level of the provided dict.

```
In [265]: data = [
    ...:     {
    ...:         "CreatedBy": {"Name": "User001"},
    ...:         "Lookup": {
    ...:             "TextField": "Some text",
    ...:             "UserField": {"Id": "ID001", "Name": "Name001"},
    ...:         },
    ...:         "Image": {"a": "b"},
    ...:     }
    ...: ]
    ...:
```

```
In [266]: pd.json_normalize(data, max_level=1)
```

```
Out[266]:
      CreatedBy.Name Lookup.TextField           Lookup.UserField Image.a
0          User001        Some text  {'Id': 'ID001', 'Name': 'Name001'}       b
```

Line delimited json

pandas is able to read and write line-delimited json files that are common in data processing pipelines using Hadoop or Spark.

For line-delimited json files, pandas can also return an iterator which reads in `chunksize` lines at a time. This can be useful for large files or to read from a stream.

```
In [267]: jsonl = """
    ...:     {"a": 1, "b": 2}
    ...:     {"a": 3, "b": 4}
    ...: """
    ...:
```

```
In [268]: df = pd.read_json(jsonl, lines=True)
```

```
In [269]: df
```

```
Out[269]:
      a   b
0   1   2
1   3   4
```

```
In [270]: df.to_json(orient="records", lines=True)
```

```
Out[270]: '{"a":1,"b":2}\n{"a":3,"b":4}\n'
```

```
# reader is an iterator that returns ``chunksize`` lines each iteration
```

```
In [271]: with pd.read_json(StringIO(jsonl), lines=True, chunksize=1) as reader:
    ...:     reader
    ...:     for chunk in reader:
```

(continues on next page)

(continued from previous page)

```
.....:     print(chunk)
.....:
Empty DataFrame
Columns: []
Index: []
   a   b
0  1   2
   a   b
1  3   4
```

Table schema

Table Schema is a spec for describing tabular datasets as a JSON object. The JSON includes information on the field names, types, and other attributes. You can use the `orient=table` to build a JSON string with two fields, `schema` and `data`.

```
In [272]: df = pd.DataFrame(
.....:     {
.....:         "A": [1, 2, 3],
.....:         "B": ["a", "b", "c"],
.....:         "C": pd.date_range("2016-01-01", freq="d", periods=3),
.....:     },
.....:     index=pd.Index(range(3), name="idx"),
.....: )
.....:

In [273]: df
Out[273]:
   A   B       C
idx
0   1   a 2016-01-01
1   2   b 2016-01-02
2   3   c 2016-01-03

In [274]: df.to_json(orient="table", date_format="iso")
Out[274]: '{"schema": {"fields": [{"name": "idx", "type": "integer"}, {"name": "A", "type": "integer"}, {"name": "B", "type": "string"}, {"name": "C", "type": "datetime"}], "primaryKey": ["idx"], "pandas_version": "1.4.0"}, "data": [{"idx": 0, "A": 1, "B": "a", "C": "2016-01-01T00:00:00.000Z"}, {"idx": 1, "A": 2, "B": "b", "C": "2016-01-02T00:00:00.000Z"}, {"idx": 2, "A": 3, "B": "c", "C": "2016-01-03T00:00:00.000Z"}]}'
```

The `schema` field contains the `fields` key, which itself contains a list of column name to type pairs, including the `Index` or `MultiIndex` (see below for a list of types). The `schema` field also contains a `primaryKey` field if the (Multi)index is unique.

The second field, `data`, contains the serialized data with the `records` orient. The index is included, and any datetimes are ISO 8601 formatted, as required by the Table Schema spec.

The full list of types supported are described in the Table Schema spec. This table shows the mapping from pandas types:

pandas type	Table Schema type
int64	integer
float64	number
bool	boolean
datetime64[ns]	datetime
timedelta64[ns]	duration
categorical	any
object	str

A few notes on the generated table schema:

- The schema object contains a `pandas_version` field. This contains the version of pandas' dialect of the schema, and will be incremented with each revision.
- All dates are converted to UTC when serializing. Even timezone naive values, which are treated as UTC with an offset of 0.

```
In [275]: from pandas.io.json import build_table_schema
```

```
In [276]: s = pd.Series(pd.date_range("2016", periods=4))
```

```
In [277]: build_table_schema(s)
```

```
Out[277]:
```

```
{'fields': [{'name': 'index', 'type': 'integer'},
            {'name': 'values', 'type': 'datetime'}],
 'primaryKey': ['index'],
 'pandas_version': '1.4.0'}
```

- datetimes with a timezone (before serializing), include an additional field `tz` with the time zone name (e.g. '`US/Central`').

```
In [278]: s_tz = pd.Series(pd.date_range("2016", periods=12, tz="US/Central"))
```

```
In [279]: build_table_schema(s_tz)
```

```
Out[279]:
```

```
{'fields': [{'name': 'index', 'type': 'integer'},
            {'name': 'values', 'type': 'datetime', 'tz': 'US/Central'}],
 'primaryKey': ['index'],
 'pandas_version': '1.4.0'}
```

- Periods are converted to timestamps before serialization, and so have the same behavior of being converted to UTC. In addition, periods will contain an additional field `freq` with the period's frequency, e.g. '`A-DEC`'.

```
In [280]: s_per = pd.Series(1, index=pd.period_range("2016", freq="A-DEC", periods=4))
```

```
In [281]: build_table_schema(s_per)
```

```
Out[281]:
```

```
{'fields': [{'name': 'index', 'type': 'datetime', 'freq': 'A-DEC'},
            {'name': 'values', 'type': 'integer'}],
 'primaryKey': ['index'],
 'pandas_version': '1.4.0'}
```

- Categoricals use the `any` type and an `enum` constraint listing the set of possible values. Additionally, an `ordered` field is included:

```
In [282]: s_cat = pd.Series(pd.Categorical(["a", "b", "a"]))

In [283]: build_table_schema(s_cat)
Out[283]:
{'fields': [{'name': 'index', 'type': 'integer'},
 {'name': 'values',
  'type': 'any',
  'constraints': {'enum': ['a', 'b']},
  'ordered': False}],
 'primaryKey': ['index'],
 'pandas_version': '1.4.0'}
```

- A `primaryKey` field, containing an array of labels, is included *if the index is unique*:

```
In [284]: s_dupe = pd.Series([1, 2], index=[1, 1])

In [285]: build_table_schema(s_dupe)
Out[285]:
{'fields': [{'name': 'index', 'type': 'integer'},
 {'name': 'values', 'type': 'integer'}],
 'pandas_version': '1.4.0'}
```

- The `primaryKey` behavior is the same with MultiIndexes, but in this case the `primaryKey` is an array:

```
In [286]: s_multi = pd.Series(1, index=pd.MultiIndex.from_product([("a", "b"), (0, 1)]))

In [287]: build_table_schema(s_multi)
Out[287]:
{'fields': [{'name': 'level_0', 'type': 'string'},
 {'name': 'level_1', 'type': 'integer'},
 {'name': 'values', 'type': 'integer'}],
 'primaryKey': FrozenList(['level_0', 'level_1']),
 'pandas_version': '1.4.0'}
```

- The default naming roughly follows these rules:
 - For series, the `object.name` is used. If that's none, then the name is `values`
 - For DataFrames, the stringified version of the column name is used
 - For Index (not MultiIndex), `index.name` is used, with a fallback to `index` if that is None.
 - For MultiIndex, `mi.names` is used. If any level has no name, then `level_<i>` is used.

`read_json` also accepts `orient='table'` as an argument. This allows for the preservation of metadata such as dtypes and index names in a round-trippable manner.

```
In [288]: df = pd.DataFrame(
    ....:     {
    ....:         "foo": [1, 2, 3, 4],
    ....:         "bar": ["a", "b", "c", "d"],
    ....:         "baz": pd.date_range("2018-01-01", freq="d", periods=4),
    ....:         "qux": pd.Categorical(["a", "b", "c", "c"]),
    ....:     },
    ....:     index=pd.Index(range(4), name="idx"),
```

(continues on next page)

(continued from previous page)

```

....: )
....:

In [289]: df
Out[289]:
    foo bar      baz qux
idx
0     1   a 2018-01-01   a
1     2   b 2018-01-02   b
2     3   c 2018-01-03   c
3     4   d 2018-01-04   c

In [290]: df.dtypes
Out[290]:
foo          int64
bar         object
baz  datetime64[ns]
qux      category
dtype: object

In [291]: df.to_json("test.json", orient="table")

In [292]: new_df = pd.read_json("test.json", orient="table")

In [293]: new_df
Out[293]:
    foo bar      baz qux
idx
0     1   a 2018-01-01   a
1     2   b 2018-01-02   b
2     3   c 2018-01-03   c
3     4   d 2018-01-04   c

In [294]: new_df.dtypes
Out[294]:
foo          int64
bar         object
baz  datetime64[ns]
qux      category
dtype: object

```

Please note that the literal string ‘index’ as the name of an `Index` is not round-trippable, nor are any names beginning with ‘level_’ within a `MultiIndex`. These are used by default in `DataFrame.to_json()` to indicate missing values and the subsequent read cannot distinguish the intent.

```

In [295]: df.index.name = "index"

In [296]: df.to_json("test.json", orient="table")

In [297]: new_df = pd.read_json("test.json", orient="table")

In [298]: print(new_df.index.name)

```

(continues on next page)

(continued from previous page)

None

When using `orient='table'` along with user-defined `ExtensionArray`, the generated schema will contain an additional `extDtype` key in the respective `fields` element. This extra key is not standard but does enable JSON roundtrips for extension types (e.g. `read_json(df.to_json(orient="table"), orient="table")`).

The `extDtype` key carries the name of the extension, if you have properly registered the `ExtensionDtype`, pandas will use said name to perform a lookup into the registry and re-convert the serialized data into your custom dtype.

2.4.3 HTML

Reading HTML content

Warning: We **highly encourage** you to read the [HTML Table Parsing gotchas](#) below regarding the issues surrounding the BeautifulSoup4/html5lib/lxml parsers.

The top-level `read_html()` function can accept an HTML string/file/URL and will parse HTML tables into list of pandas DataFrames. Let's look at a few examples.

Note: `read_html` returns a list of DataFrame objects, even if there is only a single table contained in the HTML content.

Read a URL with no options:

```
In [299]: url = "https://www.fdic.gov/resources/resolutions/bank-failures/failed-bank-list"
```

```
In [300]: dfs = pd.read_html(url)
```

```
In [301]: dfs
```

```
Out[301]:
```

	Bank Name	Bank	Acquiring Institution	AI	Closing Date	Closing	Fund	Fund	City	City	State	St	...
0	Almena State Bank	Almena			October 23, 2020	10538				KS	...

Note: The following examples are not run by the IPython evaluator due to the fact that having so many network-accessing functions slows down the documentation build. If you spot an error or an example that doesn't run, please do not hesitate to report it over on pandas [GitHub issues page](#).

Read a URL and match a table that contains specific text:

```
match = "Metcalf Bank"
df_list = pd.read_html(url, match=match)
```

Specify a header row (by default `<th>` or `<td>` elements located within a `<thead>` are used to form the column index, if multiple rows are contained within `<thead>` then a MultiIndex is created); if specified, the header row is taken from the data minus the parsed header elements (`<th>` elements).

```
dfs = pd.read_html(url, header=0)
```

Specify an index column:

```
dfs = pd.read_html(url, index_col=0)
```

Specify a number of rows to skip:

```
dfs = pd.read_html(url, skiprows=0)
```

Specify a number of rows to skip using a list (range works as well):

```
dfs = pd.read_html(url, skiprows=range(2))
```

Specify an HTML attribute:

```
dfs1 = pd.read_html(url, attrs={"id": "table"})
dfs2 = pd.read_html(url, attrs={"class": "sortable"})
print(np.array_equal(dfs1[0], dfs2[0])) # Should be True
```

Specify values that should be converted to NaN:

```
dfs = pd.read_html(url, na_values=["No Acquirer"])
```

Specify whether to keep the default set of NaN values:

```
dfs = pd.read_html(url, keep_default_na=False)
```

Specify converters for columns. This is useful for numerical text data that has leading zeros. By default columns that are numerical are cast to numeric types and the leading zeros are lost. To avoid this, we can convert these columns to strings.

```
url_mcc = "https://en.wikipedia.org/wiki/Mobile_country_code"
dfs = pd.read_html(
    url_mcc,
    match="Telekom Albania",
    header=0,
    converters={"MNC": str},
)
```

Use some combination of the above:

```
dfs = pd.read_html(url, match="Metcalf Bank", index_col=0)
```

Read in pandas to_html output (with some loss of floating point precision):

```
df = pd.DataFrame(np.random.randn(2, 2))
s = df.to_html(float_format=".4g".format)
dfin = pd.read_html(s, index_col=0)
```

The lxml backend will raise an error on a failed parse if that is the only parser you provide. If you only have a single parser you can provide just a string, but it is considered good practice to pass a list with one string if, for example, the function expects a sequence of strings. You may use:

```
dfs = pd.read_html(url, "Metcalf Bank", index_col=0, flavor=["lxml"])
```

Or you could pass flavor='lxml' without a list:

```
dfs = pd.read_html(url, "Metcalf Bank", index_col=0, flavor="lxml")
```

However, if you have bs4 and html5lib installed and pass None or ['lxml', 'bs4'] then the parse will most likely succeed. Note that *as soon as a parse succeeds, the function will return*.

```
dfs = pd.read_html(url, "Metcalf Bank", index_col=0, flavor=["lxml", "bs4"])
```

Writing to HTML files

DataFrame objects have an instance method `to_html` which renders the contents of the DataFrame as an HTML table. The function arguments are as in the method `to_string` described above.

Note: Not all of the possible options for `DataFrame.to_html` are shown here for brevity's sake. See `to_html()` for the full set of options.

```
In [307]: df = pd.DataFrame(np.random.randn(2, 2))
```

```
In [308]: df
```

```
Out[308]:
```

```
0      1  
0 -0.184744  0.496971  
1 -0.856240  1.857977
```

```
In [309]: print(df.to_html()) # raw html
```

```
<table border="1" class="dataframe">  
  <thead>  
    <tr style="text-align: right;">  
      <th></th>  
      <th>0</th>  
      <th>1</th>  
    </tr>  
  </thead>  
  <tbody>  
    <tr>  
      <th>0</th>  
      <td>-0.184744</td>  
      <td>0.496971</td>  
    </tr>  
    <tr>  
      <th>1</th>  
      <td>-0.856240</td>  
      <td>1.857977</td>  
    </tr>  
  </tbody>  
</table>
```

HTML:

The `columns` argument will limit the columns shown:

```
In [310]: print(df.to_html(columns=[0]))  
<table border="1" class="dataframe">  
  <thead>  
    <tr style="text-align: right;">  
      <th></th>  
      <th>0</th>
```

(continues on next page)

(continued from previous page)

```

</tr>
</thead>
<tbody>
<tr>
    <th>0</th>
    <td>-0.184744</td>
</tr>
<tr>
    <th>1</th>
    <td>-0.856240</td>
</tr>
</tbody>
</table>

```

HTML:

`float_format` takes a Python callable to control the precision of floating point values:

```
In [311]: print(df.to_html(float_format="{0:.10f}".format))

|   | 0             | 1            |
|---|---------------|--------------|
| 0 | -0.1847438576 | 0.4969711327 |
| 1 | -0.8562396763 | 1.8579766508 |

```

HTML:

`bold_rows` will make the row labels bold by default, but you can turn that off:

```
In [312]: print(df.to_html(bold_rows=False))

|  | 0 | 1 |
|--|---|---|
|--|---|---|

```

(continues on next page)

(continued from previous page)

```
</thead>
<tbody>
    <tr>
        <td>0</td>
        <td>-0.184744</td>
        <td>0.496971</td>
    </tr>
    <tr>
        <td>1</td>
        <td>-0.856240</td>
        <td>1.857977</td>
    </tr>
</tbody>
</table>
```

The `classes` argument provides the ability to give the resulting HTML table CSS classes. Note that these classes are *appended* to the existing '`dataframe`' class.

```
In [313]: print(df.to_html(classes=["awesome_table_class", "even_more_awesome_class"]))
<table border="1" class="dataframe awesome_table_class even_more_awesome_class">
    <thead>
        <tr style="text-align: right;">
            <th></th>
            <th>0</th>
            <th>1</th>
        </tr>
    </thead>
    <tbody>
        <tr>
            <th>0</th>
            <td>-0.184744</td>
            <td>0.496971</td>
        </tr>
        <tr>
            <th>1</th>
            <td>-0.856240</td>
            <td>1.857977</td>
        </tr>
    </tbody>
</table>
```

The `render_links` argument provides the ability to add hyperlinks to cells that contain URLs.

```
In [314]: url_df = pd.DataFrame(
    ....:     {
    ....:         "name": ["Python", "pandas"],
    ....:         "url": ["https://www.python.org/", "https://pandas.pydata.org"],
    ....:     }
    ....: )
....:
```

```
In [315]: print(url_df.to_html(render_links=True))
```

(continues on next page)

(continued from previous page)

	name	url
0	Python	https://www.python.org/
1	pandas	https://pandas.pydata.org

HTML:

Finally, the `escape` argument allows you to control whether the “<”, “>” and “&” characters escaped in the resulting HTML (by default it is True). So to get the HTML without escaped characters pass `escape=False`

```
In [316]: df = pd.DataFrame({"a": list("&<>"), "b": np.random.randn(3)})
```

Escaped:

```
In [317]: print(df.to_html())

|   | a | b         |
|---|---|-----------|
| 0 | & | -0.474063 |
| 1 | < | -0.230305 |

```

(continues on next page)

(continued from previous page)

```
<tr>
    <th>2</th>
    <td>&gt;;</td>
    <td>-0.400654</td>
</tr>
</tbody>
</table>
```

Not escaped:

```
In [318]: print(df.to_html(escape=False))
<table border="1" class="dataframe">
    <thead>
        <tr style="text-align: right;">
            <th></th>
            <th>a</th>
            <th>b</th>
        </tr>
    </thead>
    <tbody>
        <tr>
            <th>0</th>
            <td>&</td>
            <td>-0.474063</td>
        </tr>
        <tr>
            <th>1</th>
            <td><</td>
            <td>-0.230305</td>
        </tr>
        <tr>
            <th>2</th>
            <td>></td>
            <td>-0.400654</td>
        </tr>
    </tbody>
</table>
```

Note: Some browsers may not show a difference in the rendering of the previous two HTML tables.

HTML Table Parsing Gotchas

There are some versioning issues surrounding the libraries that are used to parse HTML tables in the top-level pandas `io` function `read_html`.

Issues with `lxml`

- Benefits
 - `lxml` is very fast.
 - `lxml` requires Cython to install correctly.

- Drawbacks
 - `lxml` does *not* make any guarantees about the results of its parse *unless* it is given **strictly valid markup**.
 - In light of the above, we have chosen to allow you, the user, to use the `lxml` backend, but **this backend will use `html5lib`** if `lxml` fails to parse
 - It is therefore *highly recommended* that you install both **`BeautifulSoup4`** and **`html5lib`**, so that you will still get a valid result (provided everything else is valid) even if `lxml` fails.

Issues with `BeautifulSoup4` using `lxml` as a backend

- The above issues hold here as well since **`BeautifulSoup4`** is essentially just a wrapper around a parser backend.

Issues with `BeautifulSoup4` using `html5lib` as a backend

- Benefits
 - `html5lib` is far more lenient than `lxml` and consequently deals with *real-life markup* in a much saner way rather than just, e.g., dropping an element without notifying you.
 - `html5lib` generates valid HTML5 markup from invalid markup automatically. This is extremely important for parsing HTML tables, since it guarantees a valid document. However, that does NOT mean that it is “correct”, since the process of fixing markup does not have a single definition.
 - `html5lib` is pure Python and requires no additional build steps beyond its own installation.
- Drawbacks
 - The biggest drawback to using `html5lib` is that it is slow as molasses. However consider the fact that many tables on the web are not big enough for the parsing algorithm runtime to matter. It is more likely that the bottleneck will be in the process of reading the raw text from the URL over the web, i.e., IO (input-output). For very large tables, this might not be true.

2.4.4 LaTeX

New in version 1.3.0.

Currently there are no methods to read from LaTeX, only output methods.

Writing to LaTeX files

Note: DataFrame and Styler objects currently have a `to_latex` method. We recommend using the `Styler.to_latex()` method over `DataFrame.to_latex()` due to the former’s greater flexibility with conditional styling, and the latter’s possible future deprecation.

Review the documentation for `Styler.to_latex`, which gives examples of conditional styling and explains the operation of its keyword arguments.

For simple application the following pattern is sufficient.

```
In [319]: df = pd.DataFrame([[1, 2], [3, 4]], index=["a", "b"], columns=["c", "d"])

In [320]: print(df.style.to_latex())
\begin{tabular}{lrr}
& c & d \\
a & 1 & 2
\end{tabular}
```

(continues on next page)

(continued from previous page)

```
b & 3 & 4 \\  
\end{tabular}
```

To format values before output, chain the `Styler.format` method.

```
In [321]: print(df.style.format("€ {}").to_latex())  
\begin{tabular}{lrr}  
 & c & d \\  
a & € 1 & € 2 \\  
b & € 3 & € 4 \\  
\end{tabular}
```

2.4.5 XML

Reading XML

New in version 1.3.0.

The top-level `read_xml()` function can accept an XML string/file/URL and will parse nodes and attributes into a pandas DataFrame.

Note: Since there is no standard XML structure where design types can vary in many ways, `read_xml` works best with flatter, shallow versions. If an XML document is deeply nested, use the `stylesheet` feature to transform XML into a flatter version.

Let's look at a few examples.

Read an XML string:

```
In [322]: xml = """<?xml version="1.0" encoding="UTF-8"?>  
.....: <bookstore>  
.....:   <book category="cooking">  
.....:     <title lang="en">Everyday Italian</title>  
.....:     <author>Giada De Laurentiis</author>  
.....:     <year>2005</year>  
.....:     <price>30.00</price>  
.....:   </book>  
.....:   <book category="children">  
.....:     <title lang="en">Harry Potter</title>  
.....:     <author>J. K. Rowling</author>  
.....:     <year>2005</year>  
.....:     <price>29.99</price>  
.....:   </book>  
.....:   <book category="web">  
.....:     <title lang="en">Learning XML</title>  
.....:     <author>Erik T. Ray</author>  
.....:     <year>2003</year>  
.....:     <price>39.95</price>  
.....:   </book>  
.....: </bookstore>""""
```

(continues on next page)

(continued from previous page)

```
In [323]: df = pd.read_xml(xml)
```

```
In [324]: df
```

```
Out[324]:
```

	category	title	author	year	price
0	cooking	Everyday Italian	Giada De Laurentiis	2005	30.00
1	children	Harry Potter	J K. Rowling	2005	29.99
2	web	Learning XML	Erik T. Ray	2003	39.95

Read a URL with no options:

```
In [325]: df = pd.read_xml("https://www.w3schools.com/xml/books.xml")
```

```
In [326]: df
```

```
Out[326]:
```

	category	title	author	year	price	cover
0	cooking	Everyday Italian	Giada De Laurentiis	2005	30.00	None
1	children	Harry Potter	J K. Rowling	2005	29.99	None
2	web	XQuery Kick Start	Vaidyanathan Nagarajan	2003	49.99	None
3	web	Learning XML	Erik T. Ray	2003	39.95	paperback

Read in the content of the “books.xml” file and pass it to `read_xml` as a string:

```
In [327]: with open(file_path, "r") as f:
    .....
    df = pd.read_xml(f.read())
    .....
```

```
In [328]: df
```

```
Out[328]:
```

	category	title	author	year	price
0	cooking	Everyday Italian	Giada De Laurentiis	2005	30.00
1	children	Harry Potter	J K. Rowling	2005	29.99
2	web	Learning XML	Erik T. Ray	2003	39.95

Read in the content of the “books.xml” as instance of `StringIO` or `BytesIO` and pass it to `read_xml`:

```
In [329]: with open(file_path, "r") as f:
    .....
    sio = StringIO(f.read())
    .....
```

```
In [330]: df = pd.read_xml(sio)
```

```
In [331]: df
```

```
Out[331]:
```

	category	title	author	year	price
0	cooking	Everyday Italian	Giada De Laurentiis	2005	30.00
1	children	Harry Potter	J K. Rowling	2005	29.99
2	web	Learning XML	Erik T. Ray	2003	39.95

```
In [332]: with open(file_path, "rb") as f:
    .....
    bio = BytesIO(f.read())
```

(continues on next page)

(continued from previous page)

```
....:  

In [333]: df = pd.read_xml(bio)  

In [334]: df  

Out[334]:  

   category          title        author  year  price
0   cooking  Everyday Italian  Giada De Laurentiis  2005  30.00
1  children      Harry Potter  J K. Rowling  2005  29.99
2     web    Learning XML  Erik T. Ray  2003  39.95
```

Even read XML from AWS S3 buckets such as Python Software Foundation's IRS 990 Form:

```
In [335]: df = pd.read_xml(  

....:     "s3://irs-form-990/201923199349319487_public.xml",  

....:     xpath=".//irs:Form990PartVIISectionAGrp",  

....:     namespaces={"irs": "http://www.irs.gov/efile"}  

....: )  

....:  

In [336]: df  

Out[336]:  

   PersonNm           TitleTxt ...  

  ↵ OtherCompensationAmt HighestCompensatedEmployeeInd  

0       Naomi Ceder             Chair ...  

  ↵ 0                     None  

1       Van Lindberg  Vice Chair, General Counsel ...  

  ↵ 0                     None  

2       Kurt Kaiser            Treasurer ...  

  ↵ 0                     None

19      Guido van Rossum            President ...  

  ↵ 0                     None  

20 Ernest W Durbin III  Director of Infrastructure, PyCon Chair ...  

  ↵ 0                     X  

  
[21 rows x 10 columns]
```

With `lxml` as default parser, you access the full-featured XML library that extends Python's ElementTree API. One powerful tool is ability to query nodes selectively or conditionally with more expressive XPath:

```
In [337]: df = pd.read_xml(file_path, xpath="//book[year=2005]")
```

```
In [338]: df
```

```
Out[338]:
```

	category	title	author	year	price
0	cooking	Everyday Italian	Giada De Laurentiis	2005	30.00
1	children	Harry Potter	J K. Rowling	2005	29.99

Specify only elements or only attributes to parse:

```
In [339]: df = pd.read_xml(file_path, elems_only=True)
```

```
In [340]: df
```

```
Out[340]:
```

	title	author	year	price
0	Everyday Italian	Giada De Laurentiis	2005	30.00
1	Harry Potter	J K. Rowling	2005	29.99
2	Learning XML	Erik T. Ray	2003	39.95

```
In [341]: df = pd.read_xml(file_path, attrs_only=True)
```

```
In [342]: df
```

```
Out[342]:
```

	category
0	cooking
1	children
2	web

XML documents can have namespaces with prefixes and default namespaces without prefixes both of which are denoted with a special attribute `xmlns`. In order to parse by node under a namespace context, `xpath` must reference a prefix.

For example, below XML contains a namespace with prefix, `doc`, and URI at `https://example.com`. In order to parse `doc:row` nodes, `namespaces` must be used.

```
In [343]: xml = """<?xml version='1.0' encoding='utf-8'?>
..... <doc:row xmlns:doc="https://example.com">
.....   <doc:shape>square</doc:shape>
.....   <doc:degrees>360</doc:degrees>
.....   <doc:sides>4.0</doc:sides>
..... </doc:row>
..... <doc:row>
.....   <doc:shape>circle</doc:shape>
.....   <doc:degrees>360</doc:degrees>
.....   <doc:sides/>
..... </doc:row>
..... <doc:row>
.....   <doc:shape>triangle</doc:shape>
.....   <doc:degrees>180</doc:degrees>
.....   <doc:sides>3.0</doc:sides>
..... </doc:row>
..... </doc:row>"""
..... :
```

(continues on next page)

(continued from previous page)

```
In [344]: df = pd.read_xml(xml,
.....:                     xpath="//doc:row",
.....:                     namespaces={"doc": "https://example.com"})
.....:

In [345]: df
Out[345]:
      shape  degrees  sides
0    square     360    4.0
1   circle     360    NaN
2 triangle     180    3.0
```

Similarly, an XML document can have a default namespace without prefix. Failing to assign a temporary prefix will return no nodes and raise a `ValueError`. But assigning *any* temporary name to correct URI allows parsing by nodes.

```
In [346]: xml = """<?xml version='1.0' encoding='utf-8'?>
.....: <data xmlns="https://example.com">
.....:   <row>
.....:     <shape>square</shape>
.....:     <degrees>360</degrees>
.....:     <sides>4.0</sides>
.....:   </row>
.....:   <row>
.....:     <shape>circle</shape>
.....:     <degrees>360</degrees>
.....:     <sides/>
.....:   </row>
.....:   <row>
.....:     <shape>triangle</shape>
.....:     <degrees>180</degrees>
.....:     <sides>3.0</sides>
.....:   </row>
.....: </data>"""
.....:

In [347]: df = pd.read_xml(xml,
.....:                     xpath("//pandas:row",
.....:                           namespaces={"pandas": "https://example.com"}))
.....:

In [348]: df
Out[348]:
      shape  degrees  sides
0    square     360    4.0
1   circle     360    NaN
2 triangle     180    3.0
```

However, if XPath does not reference node names such as `default, /*`, then `namespaces` is not required.

With `lxml` as parser, you can flatten nested XML documents with an XSLT script which also can be string/file/URL types. As background, `XSLT` is a special-purpose language written in a special XML file that can transform original XML documents into other XML, HTML, even text (CSV, JSON, etc.) using an XSLT processor.

For example, consider this somewhat nested structure of Chicago “L” Rides where station and rides elements encapsulate data in their own sections. With below XSLT, `lxml` can transform original nested document into a flatter output (as shown below for demonstration) for easier parse into DataFrame:

```
In [349]: xml = """<?xml version='1.0' encoding='utf-8'?>
....: <response>
....:   <row>
....:     <station id="40850" name="Library"/>
....:     <month>2020-09-01T00:00:00</month>
....:     <rides>
....:       <avg_weekday_rides>864.2</avg_weekday_rides>
....:       <avg_saturday_rides>534</avg_saturday_rides>
....:       <avg_sunday_holiday_rides>417.2</avg_sunday_holiday_rides>
....:     </rides>
....:   </row>
....:   <row>
....:     <station id="41700" name="Washington/Wabash"/>
....:     <month>2020-09-01T00:00:00</month>
....:     <rides>
....:       <avg_weekday_rides>2707.4</avg_weekday_rides>
....:       <avg_saturday_rides>1909.8</avg_saturday_rides>
....:       <avg_sunday_holiday_rides>1438.6</avg_sunday_holiday_rides>
....:     </rides>
....:   </row>
....:   <row>
....:     <station id="40380" name="Clark/Lake"/>
....:     <month>2020-09-01T00:00:00</month>
....:     <rides>
....:       <avg_weekday_rides>2949.6</avg_weekday_rides>
....:       <avg_saturday_rides>1657</avg_saturday_rides>
....:       <avg_sunday_holiday_rides>1453.8</avg_sunday_holiday_rides>
....:     </rides>
....:   </row>
....: </response>"""
....:
```

```
In [350]: xsl = """<xsl:stylesheet version="1.0" xmlns:xsl="http://www.w3.org/1999/XSL/
←Transform">
....:   <xsl:output method="xml" omit-xml-declaration="no" indent="yes"/>
....:   <xsl:strip-space elements="*"/>
....:   <xsl:template match="/response">
....:     <xsl:copy>
....:       <xsl:apply-templates select="row"/>
....:     </xsl:copy>
....:   </xsl:template>
....:   <xsl:template match="row">
....:     <xsl:copy>

Writing XML

New in version 1.3.0.

DataFrame objects have an instance method `to_xml` which renders the contents of the DataFrame as an XML document.

Note: This method does not support special properties of XML including DTD, CData, XSD schemas, processing instructions, comments, and others. Only namespaces at the root level is supported. However, `stylesheet` allows design changes after initial output.

Let's look at a few examples.

Write an XML without options:

```
In [354]: geom_df = pd.DataFrame(
.....:     {
.....:         "shape": ["square", "circle", "triangle"],
.....:         "degrees": [360, 360, 180],
.....:         "sides": [4, np.nan, 3],
.....:     }
.....: )
.....:
```

```
In [355]: print(geom_df.to_xml())
<?xml version='1.0' encoding='utf-8'?>
<data>
<row>
<index>0</index>
<shape>square</shape>
<degrees>360</degrees>
<sides>4.0</sides>
</row>
<row>
<index>1</index>
<shape>circle</shape>
<degrees>360</degrees>
<sides/>
</row>
<row>
<index>2</index>
<shape>triangle</shape>
<degrees>180</degrees>
<sides>3.0</sides>
</row>
</data>
```

Write an XML with new root and row name:

```
In [356]: print(geom_df.to_xml(root_name="geometry", row_name="objects"))
<?xml version='1.0' encoding='utf-8'?>
<geometry>
<objects>
```

(continues on next page)

(continued from previous page)

```

<index>0</index>
<shape>square</shape>
<degrees>360</degrees>
<sides>4.0</sides>
</objects>
<objects>
<index>1</index>
<shape>circle</shape>
<degrees>360</degrees>
<sides/>
</objects>
<objects>
<index>2</index>
<shape>triangle</shape>
<degrees>180</degrees>
<sides>3.0</sides>
</objects>
</geometry>

```

Write an attribute-centric XML:

```
In [357]: print(geom_df.to_xml(attr_cols=geom_df.columns.tolist()))
<?xml version='1.0' encoding='utf-8'?>
<data>
    <row index="0" shape="square" degrees="360" sides="4.0"/>
    <row index="1" shape="circle" degrees="360"/>
    <row index="2" shape="triangle" degrees="180" sides="3.0"/>
</data>
```

Write a mix of elements and attributes:

```
In [358]: print(
    ....:     geom_df.to_xml(
    ....:         index=False,
    ....:         attr_cols=['shape'],
    ....:         elem_cols=['degrees', 'sides'])
    ....:
....:<?xml version='1.0' encoding='utf-8'?>
<data>
    <row shape="square">
        <degrees>360</degrees>
        <sides>4.0</sides>
    </row>
    <row shape="circle">
        <degrees>360</degrees>
        <sides/>
    </row>
    <row shape="triangle">
        <degrees>180</degrees>
        <sides>3.0</sides>
    </row>
</data>
```

Any `DataFrames` with hierarchical columns will be flattened for XML element names with levels delimited by underscores:

```
In [359]: ext_geom_df = pd.DataFrame(
...:     {
...:         "type": ["polygon", "other", "polygon"],
...:         "shape": ["square", "circle", "triangle"],
...:         "degrees": [360, 360, 180],
...:         "sides": [4, np.nan, 3],
...:     }
...: )
...:

In [360]: pvt_df = ext_geom_df.pivot_table(index='shape',
...:                                         columns='type',
...:                                         values=['degrees', 'sides'],
...:                                         aggfunc='sum')
...:

In [361]: pvt_df
Out[361]:
   degrees      sides
type    other polygon other polygon
shape
circle    360.0      NaN  0.0      NaN
square      NaN    360.0      NaN  4.0
triangle     NaN    180.0      NaN  3.0

In [362]: print(pvt_df.to_xml())
<?xml version='1.0' encoding='utf-8'?>
<data>
  <row>
    <shape>circle</shape>
    <degrees_other>360.0</degrees_other>
    <degrees_polygon/>
    <sides_other>0.0</sides_other>
    <sides_polygon/>
  </row>
  <row>
    <shape>square</shape>
    <degrees_other/>
    <degrees_polygon>360.0</degrees_polygon>
    <sides_other/>
    <sides_polygon>4.0</sides_polygon>
  </row>
  <row>
    <shape>triangle</shape>
    <degrees_other/>
    <degrees_polygon>180.0</degrees_polygon>
    <sides_other/>
    <sides_polygon>3.0</sides_polygon>
  </row>
</data>
```

Write an XML with default namespace:

```
In [363]: print(geom_df.to_xml(namespaces={"": "https://example.com"}))  
<?xml version='1.0' encoding='utf-8'?>  
<data xmlns="https://example.com">  
  <row>  
    <index>0</index>  
    <shape>square</shape>  
    <degrees>360</degrees>  
    <sides>4.0</sides>  
  </row>  
  <row>  
    <index>1</index>  
    <shape>circle</shape>  
    <degrees>360</degrees>  
    <sides/>  
  </row>  
  <row>  
    <index>2</index>  
    <shape>triangle</shape>  
    <degrees>180</degrees>  
    <sides>3.0</sides>  
  </row>  
</data>
```

Write an XML with namespace prefix:

```
In [364]: print(  
.....:     geom_df.to_xml(namespaces={"doc": "https://example.com"},  
.....:                           prefix="doc")  
.....:  
.....:  
<?xml version='1.0' encoding='utf-8'?>  
<doc:data xmlns:doc="https://example.com">  
  <doc:row>  
    <doc:index>0</doc:index>  
    <doc:shape>square</doc:shape>  
    <doc:degrees>360</doc:degrees>  
    <doc:sides>4.0</doc:sides>  
  </doc:row>  
  <doc:row>  
    <doc:index>1</doc:index>  
    <doc:shape>circle</doc:shape>  
    <doc:degrees>360</doc:degrees>  
    <doc:sides/>  
  </doc:row>  
  <doc:row>  
    <doc:index>2</doc:index>  
    <doc:shape>triangle</doc:shape>  
    <doc:degrees>180</doc:degrees>  
    <doc:sides>3.0</doc:sides>  
  </doc:row>  
</doc:data>
```

Write an XML without declaration or pretty print:

```
In [365]: print(
    ....:     geom_df.to_xml(xml_declaration=False,
    ....:                 pretty_print=False)
    ....:
....:<data><row><index>0</index><shape>square</shape><degrees>360</degrees><sides>4.0</sides>
-></row><row><index>1</index><shape>circle</shape><degrees>360</degrees><sides/></row>
-><row><index>2</index><shape>triangle</shape><degrees>180</degrees><sides>3.0</sides></
->row></data>
```

Write an XML and transform with stylesheet:

```
In [366]: xsl = """<xsl:stylesheet version="1.0" xmlns:xsl="http://www.w3.org/1999/XSL/
-+Transform">
    ....:     <xsl:output method="xml" omit-xml-declaration="no" indent="yes"/>
    ....:     <xsl:strip-space elements="*"/>
    ....:     <xsl:template match="/data">
    ....:         <geometry>
    ....:             <xsl:apply-templates select="row"/>
    ....:         </geometry>
    ....:     </xsl:template>
    ....:     <xsl:template match="row">
    ....:         <object index="{index}">
    ....:             <xsl:if test="shape!='circle'">
    ....:                 <xsl:attribute name="type">polygon</xsl:attribute>
    ....:             </xsl:if>
    ....:             <xsl:copy-of select="shape"/>
    ....:             <property>
    ....:                 <xsl:copy-of select="degrees|sides"/>
    ....:             </property>
    ....:         </object>
    ....:     </xsl:template>
    ....: </xsl:stylesheet>"""
    ....:
```

```
In [367]: print(geom_df.to_xml(stylesheets=xsl))
<?xml version="1.0"?>
<geometry>
<object index="0" type="polygon">
<shape>square</shape>
<property>
<degrees>360</degrees>
<sides>4.0</sides>
</property>
</object>
<object index="1">
<shape>circle</shape>
<property>
<degrees>360</degrees>
<sides/>
</property>
</object>
```

(continues on next page)

(continued from previous page)

```
<object index="2" type="polygon">
    <shape>triangle</shape>
    <property>
        <degrees>180</degrees>
        <sides>3.0</sides>
    </property>
</object>
</geometry>
```

XML Final Notes

- All XML documents adhere to [W3C specifications](#). Both `etree` and `lxml` parsers will fail to parse any markup document that is not well-formed or follows XML syntax rules. Do be aware HTML is not an XML document unless it follows XHTML specs. However, other popular markup types including KML, XAML, RSS, MusicML, MathML are compliant [XML schemas](#).
- For above reason, if your application builds XML prior to pandas operations, use appropriate DOM libraries like `etree` and `lxml` to build the necessary document and not by string concatenation or regex adjustments. Always remember XML is a *special* text file with markup rules.
- With very large XML files (several hundred MBs to GBs), XPath and XSLT can become memory-intensive operations. Be sure to have enough available RAM for reading and writing to large XML files (roughly about 5 times the size of text).
- Because XSLT is a programming language, use it with caution since such scripts can pose a security risk in your environment and can run large or infinite recursive operations. Always test scripts on small fragments before full run.
- The `etree` parser supports all functionality of both `read_xml` and `to_xml` except for complex XPath and any XSLT. Though limited in features, `etree` is still a reliable and capable parser and tree builder. Its performance may trail `lxml` to a certain degree for larger files but relatively unnoticeable on small to medium size files.

2.4.6 Excel files

The `read_excel()` method can read Excel 2007+ (`.xlsx`) files using the `openpyxl` Python module. Excel 2003 (`.xls`) files can be read using `xlrd`. Binary Excel (`.xlsb`) files can be read using `pyxlsb`. The `to_excel()` instance method is used for saving a `DataFrame` to Excel. Generally the semantics are similar to working with `csv` data. See the [cookbook](#) for some advanced strategies.

Warning: The `xlwt` package for writing old-style `.xls` excel files is no longer maintained. The `xlrd` package is now only for reading old-style `.xls` files.

Before pandas 1.3.0, the default argument `engine=None` to `read_excel()` would result in using the `xlrd` engine in many cases, including new Excel 2007+ (`.xlsx`) files. pandas will now default to using the `openpyxl` engine.

It is strongly encouraged to install `openpyxl` to read Excel 2007+ (`.xlsx`) files. **Please do not report issues when using ``xlrd`` to read ``.xlsx`` files.** This is no longer supported, switch to using `openpyxl` instead.

Attempting to use the the `xlwt` engine will raise a `FutureWarning` unless the option `io.excel.xls.writer` is set to "xlwt". While this option is now deprecated and will also raise a `FutureWarning`, it can be globally set and the warning suppressed. Users are recommended to write `.xlsx` files using the `openpyxl` engine instead.

Reading Excel files

In the most basic use-case, `read_excel` takes a path to an Excel file, and the `sheet_name` indicating which sheet to parse.

```
# Returns a DataFrame
pd.read_excel("path_to_file.xls", sheet_name="Sheet1")
```

ExcelFile class

To facilitate working with multiple sheets from the same file, the `ExcelFile` class can be used to wrap the file and can be passed into `read_excel`. There will be a performance benefit for reading multiple sheets as the file is read into memory only once.

```
xlsx = pd.ExcelFile("path_to_file.xls")
df = pd.read_excel(xlsx, "Sheet1")
```

The `ExcelFile` class can also be used as a context manager.

```
with pd.ExcelFile("path_to_file.xls") as xls:
    df1 = pd.read_excel(xls, "Sheet1")
    df2 = pd.read_excel(xls, "Sheet2")
```

The `sheet_names` property will generate a list of the sheet names in the file.

The primary use-case for an `ExcelFile` is parsing multiple sheets with different parameters:

```
data = {}
# For when Sheet1's format differs from Sheet2
with pd.ExcelFile("path_to_file.xls") as xls:
    data["Sheet1"] = pd.read_excel(xls, "Sheet1", index_col=None, na_values=["NA"])
    data["Sheet2"] = pd.read_excel(xls, "Sheet2", index_col=1)
```

Note that if the same parsing parameters are used for all sheets, a list of sheet names can simply be passed to `read_excel` with no loss in performance.

```
# using the ExcelFile class
data = {}
with pd.ExcelFile("path_to_file.xls") as xls:
    data["Sheet1"] = pd.read_excel(xls, "Sheet1", index_col=None, na_values=["NA"])
    data["Sheet2"] = pd.read_excel(xls, "Sheet2", index_col=None, na_values=["NA"])

# equivalent using the read_excel function
data = pd.read_excel(
    "path_to_file.xls", ["Sheet1", "Sheet2"], index_col=None, na_values=["NA"]
)
```

`ExcelFile` can also be called with a `xlrd.book.Book` object as a parameter. This allows the user to control how the excel file is read. For example, sheets can be loaded on demand by calling `xlrd.open_workbook()` with `on_demand=True`.

```
import xlrd
```

(continues on next page)

(continued from previous page)

```
xlrd_book = xlrd.open_workbook("path_to_file.xls", on_demand=True)
with pd.ExcelFile(xlrd_book) as xls:
    df1 = pd.read_excel(xls, "Sheet1")
    df2 = pd.read_excel(xls, "Sheet2")
```

Specifying sheets

Note: The second argument is `sheet_name`, not to be confused with `ExcelFile.sheet_names`.

Note: An ExcelFile's attribute `sheet_names` provides access to a list of sheets.

- The arguments `sheet_name` allows specifying the sheet or sheets to read.
- The default value for `sheet_name` is 0, indicating to read the first sheet
- Pass a string to refer to the name of a particular sheet in the workbook.
- Pass an integer to refer to the index of a sheet. Indices follow Python convention, beginning at 0.
- Pass a list of either strings or integers, to return a dictionary of specified sheets.
- Pass a `None` to return a dictionary of all available sheets.

```
# Returns a DataFrame
pd.read_excel("path_to_file.xls", "Sheet1", index_col=None, na_values=["NA"])
```

Using the sheet index:

```
# Returns a DataFrame
pd.read_excel("path_to_file.xls", 0, index_col=None, na_values=["NA"])
```

Using all default values:

```
# Returns a DataFrame
pd.read_excel("path_to_file.xls")
```

Using `None` to get all sheets:

```
# Returns a dictionary of DataFrames
pd.read_excel("path_to_file.xls", sheet_name=None)
```

Using a list to get multiple sheets:

```
# Returns the 1st and 4th sheet, as a dictionary of DataFrames.
pd.read_excel("path_to_file.xls", sheet_name=[ "Sheet1", 3])
```

`read_excel` can read more than one sheet, by setting `sheet_name` to either a list of sheet names, a list of sheet positions, or `None` to read all sheets. Sheets can be specified by sheet index or sheet name, using an integer or string, respectively.

Reading a MultiIndex

`read_excel` can read a MultiIndex index, by passing a list of columns to `index_col` and a MultiIndex column by passing a list of rows to `header`. If either the `index` or `columns` have serialized level names those will be read in as well by specifying the rows/columns that make up the levels.

For example, to read in a MultiIndex index without names:

```
In [368]: df = pd.DataFrame(
.....:     {"a": [1, 2, 3, 4], "b": [5, 6, 7, 8]},
.....:     index=pd.MultiIndex.from_product([["a", "b"], ["c", "d"]]),
.....: )
.....:

In [369]: df.to_excel("path_to_file.xlsx")

In [370]: df = pd.read_excel("path_to_file.xlsx", index_col=[0, 1])

In [371]: df
Out[371]:
   a   b
a c  1  5
  d  2  6
b c  3  7
  d  4  8
```

If the index has level names, they will parsed as well, using the same parameters.

```
In [372]: df.index = df.index.set_names(["lvl1", "lvl2"])

In [373]: df.to_excel("path_to_file.xlsx")

In [374]: df = pd.read_excel("path_to_file.xlsx", index_col=[0, 1])

In [375]: df
Out[375]:
   a   b
lvl1 lvl2
a   c    1  5
    d    2  6
b   c    3  7
    d    4  8
```

If the source file has both MultiIndex index and columns, lists specifying each should be passed to `index_col` and `header`:

```
In [376]: df.columns = pd.MultiIndex.from_product([["a"], ["b", "d"]], names=["c1", "c2"])
          ↵

In [377]: df.to_excel("path_to_file.xlsx")

In [378]: df = pd.read_excel("path_to_file.xlsx", index_col=[0, 1], header=[0, 1])

In [379]: df
```

(continues on next page)

(continued from previous page)

Out[379]:

```
c1      a  
c2      b  d  
l1l1  l1l2  
a    c    1  5  
     d    2  6  
b    c    3  7  
     d    4  8
```

Parsing specific columns

It is often the case that users will insert columns to do temporary computations in Excel and you may not want to read in those columns. `read_excel` takes a `usecols` keyword to allow you to specify a subset of columns to parse.

Changed in version 1.0.0.

Passing in an integer for `usecols` will no longer work. Please pass in a list of ints from 0 to `usecols` inclusive instead.

You can specify a comma-delimited set of Excel columns and ranges as a string:

```
pd.read_excel("path_to_file.xls", "Sheet1", usecols="A,C:E")
```

If `usecols` is a list of integers, then it is assumed to be the file column indices to be parsed.

```
pd.read_excel("path_to_file.xls", "Sheet1", usecols=[0, 2, 3])
```

Element order is ignored, so `usecols=[0, 1]` is the same as `[1, 0]`.

If `usecols` is a list of strings, it is assumed that each string corresponds to a column name provided either by the user in `names` or inferred from the document header row(s). Those strings define which columns will be parsed:

```
pd.read_excel("path_to_file.xls", "Sheet1", usecols=["foo", "bar"])
```

Element order is ignored, so `usecols=['baz', 'joe']` is the same as `['joe', 'baz']`.

If `usecols` is callable, the callable function will be evaluated against the column names, returning names where the callable function evaluates to True.

```
pd.read_excel("path_to_file.xls", "Sheet1", usecols=lambda x: x.isalpha())
```

Parsing dates

Datetime-like values are normally automatically converted to the appropriate `dtype` when reading the excel file. But if you have a column of strings that *look* like dates (but are not actually formatted as dates in excel), you can use the `parse_dates` keyword to parse those strings to datetimes:

```
pd.read_excel("path_to_file.xls", "Sheet1", parse_dates=["date_strings"])
```

Cell converters

It is possible to transform the contents of Excel cells via the `converters` option. For instance, to convert a column to boolean:

```
pd.read_excel("path_to_file.xls", "Sheet1", converters={"MyBools": bool})
```

This options handles missing values and treats exceptions in the converters as missing data. Transformations are applied cell by cell rather than to the column as a whole, so the array dtype is not guaranteed. For instance, a column of integers with missing values cannot be transformed to an array with integer dtype, because NaN is strictly a float. You can manually mask missing data to recover integer dtype:

```
def cfun(x):
    return int(x) if x else -1

pd.read_excel("path_to_file.xls", "Sheet1", converters={"MyInts": cfun})
```

Dtype specifications

As an alternative to converters, the type for an entire column can be specified using the `dtype` keyword, which takes a dictionary mapping column names to types. To interpret data with no type inference, use the type `str` or `object`.

```
pd.read_excel("path_to_file.xls", dtype={"MyInts": "int64", "MyText": str})
```

Writing Excel files

Writing Excel files to disk

To write a `DataFrame` object to a sheet of an Excel file, you can use the `to_excel` instance method. The arguments are largely the same as `to_csv` described above, the first argument being the name of the excel file, and the optional second argument the name of the sheet to which the `DataFrame` should be written. For example:

```
df.to_excel("path_to_file.xlsx", sheet_name="Sheet1")
```

Files with a `.xls` extension will be written using `xlwt` and those with a `.xlsx` extension will be written using `xlsxwriter` (if available) or `openpyxl`.

The `DataFrame` will be written in a way that tries to mimic the REPL output. The `index_label` will be placed in the second row instead of the first. You can place it in the first row by setting the `merge_cells` option in `to_excel()` to `False`:

```
df.to_excel("path_to_file.xlsx", index_label="label", merge_cells=False)
```

In order to write separate `DataFrames` to separate sheets in a single Excel file, one can pass an `ExcelWriter`.

```
with pd.ExcelWriter("path_to_file.xlsx") as writer:
    df1.to_excel(writer, sheet_name="Sheet1")
    df2.to_excel(writer, sheet_name="Sheet2")
```

Writing Excel files to memory

pandas supports writing Excel files to buffer-like objects such as `StringIO` or `BytesIO` using `ExcelWriter`.

```
from io import BytesIO

bio = BytesIO()

# By setting the 'engine' in the ExcelWriter constructor.
writer = pd.ExcelWriter(bio, engine="xlsxwriter")
df.to_excel(writer, sheet_name="Sheet1")

# Save the workbook
writer.save()

# Seek to the beginning and read to copy the workbook to a variable in memory
bio.seek(0)
workbook = bio.read()
```

Note: `engine` is optional but recommended. Setting the engine determines the version of workbook produced. Setting `engine='xlrd'` will produce an Excel 2003-format workbook (`.xls`). Using either '`openpyxl`' or '`xlsxwriter`' will produce an Excel 2007-format workbook (`.xlsx`). If omitted, an Excel 2007-formatted workbook is produced.

Excel writer engines

Deprecated since version 1.2.0: As the `xlwt` package is no longer maintained, the `xlwt` engine will be removed from a future version of pandas. This is the only engine in pandas that supports writing to `.xls` files.

pandas chooses an Excel writer via two methods:

1. the `engine` keyword argument
2. the filename extension (via the default specified in config options)

By default, pandas uses the `XlsxWriter` for `.xlsx`, `openpyxl` for `.xlsm`, and `xlwt` for `.xls` files. If you have multiple engines installed, you can set the default engine through *setting the config options* `io.excel.xlsx.writer` and `io.excel.xls.writer`. pandas will fall back on `openpyxl` for `.xlsx` files if `Xlsxwriter` is not available.

To specify which writer you want to use, you can pass an engine keyword argument to `to_excel` and to `ExcelWriter`. The built-in engines are:

- `openpyxl`: version 2.4 or higher is required
- `xlsxwriter`
- `xlwt`

```
# By setting the 'engine' in the DataFrame 'to_excel()' methods.
df.to_excel("path_to_file.xlsx", sheet_name="Sheet1", engine="xlsxwriter")

# By setting the 'engine' in the ExcelWriter constructor.
writer = pd.ExcelWriter("path_to_file.xlsx", engine="xlsxwriter")

# Or via pandas configuration.
```

(continues on next page)

(continued from previous page)

```
from pandas import options # noqa: E402
options.io.excel.xlsx.writer = "xlsxwriter"
df.to_excel("path_to_file.xlsx", sheet_name="Sheet1")
```

Style and formatting

The look and feel of Excel worksheets created from pandas can be modified using the following parameters on the DataFrame's `to_excel` method.

- `float_format` : Format string for floating point numbers (default `None`).
- `freeze_panes` : A tuple of two integers representing the bottommost row and rightmost column to freeze. Each of these parameters is one-based, so `(1, 1)` will freeze the first row and first column (default `None`).

Using the `Xlsxwriter` engine provides many options for controlling the format of an Excel worksheet created with the `to_excel` method. Excellent examples can be found in the `Xlsxwriter` documentation here: https://xlsxwriter.readthedocs.io/working_with_pandas.html

2.4.7 OpenDocument Spreadsheets

New in version 0.25.

The `read_excel()` method can also read OpenDocument spreadsheets using the `odfpy` module. The semantics and features for reading OpenDocument spreadsheets match what can be done for *Excel files* using `engine='odf'`.

```
# Returns a DataFrame
pd.read_excel("path_to_file.ods", engine="odf")
```

Note: Currently pandas only supports *reading* OpenDocument spreadsheets. Writing is not implemented.

2.4.8 Binary Excel (.xlsb) files

New in version 1.0.0.

The `read_excel()` method can also read binary Excel files using the `pyxlsb` module. The semantics and features for reading binary Excel files mostly match what can be done for *Excel files* using `engine='pyxlsb'`. `pyxlsb` does not recognize datetime types in files and will return floats instead.

```
# Returns a DataFrame
pd.read_excel("path_to_file.xlsb", engine="pyxlsb")
```

Note: Currently pandas only supports *reading* binary Excel files. Writing is not implemented.

2.4.9 Clipboard

A handy way to grab data is to use the `read_clipboard()` method, which takes the contents of the clipboard buffer and passes them to the `read_csv` method. For instance, you can copy the following text to the clipboard (CTRL-C on many operating systems):

```
A B C  
x 1 4 p  
y 2 5 q  
z 3 6 r
```

And then import the data directly to a `DataFrame` by calling:

```
>>> clipdf = pd.read_clipboard()  
>>> clipdf  
A B C  
x 1 4 p  
y 2 5 q  
z 3 6 r
```

The `to_clipboard` method can be used to write the contents of a `DataFrame` to the clipboard. Following which you can paste the clipboard contents into other applications (CTRL-V on many operating systems). Here we illustrate writing a `DataFrame` into clipboard and reading it back.

```
>>> df = pd.DataFrame(  
...     {"A": [1, 2, 3], "B": [4, 5, 6], "C": ["p", "q", "r"]}, index=["x", "y", "z"]  
... )  
  
>>> df  
A B C  
x 1 4 p  
y 2 5 q  
z 3 6 r  
>>> df.to_clipboard()  
>>> pd.read_clipboard()  
A B C  
x 1 4 p  
y 2 5 q  
z 3 6 r
```

We can see that we got the same content back, which we had earlier written to the clipboard.

Note: You may need to install `xclip` or `xsel` (with `PyQt5`, `PyQt4` or `qtpy`) on Linux to use these methods.

2.4.10 Pickling

All pandas objects are equipped with `to_pickle` methods which use Python's cPickle module to save data structures to disk using the pickle format.

```
In [380]: df
```

```
Out[380]:
```

```
c1      a
c2      b  d
l1l2
a    c    1  5
      d    2  6
b    c    3  7
      d    4  8
```

```
In [381]: df.to_pickle("foo.pkl")
```

The `read_pickle` function in the pandas namespace can be used to load any pickled pandas object (or any other pickled object) from file:

```
In [382]: pd.read_pickle("foo.pkl")
```

```
Out[382]:
```

```
c1      a
c2      b  d
l1l2
a    c    1  5
      d    2  6
b    c    3  7
      d    4  8
```

Warning: Loading pickled data received from untrusted sources can be unsafe.

See: <https://docs.python.org/3/library/pickle.html>

Warning: `read_pickle()` is only guaranteed backwards compatible back to pandas version 0.20.3

Compressed pickle files

`read_pickle()`, `DataFrame.to_pickle()` and `Series.to_pickle()` can read and write compressed pickle files. The compression types of gzip, bz2, xz, zstd are supported for reading and writing. The zip file format only supports reading and must contain only one data file to be read.

The compression type can be an explicit parameter or be inferred from the file extension. If 'infer', then use gzip, bz2, zip, xz, zstd if filename ends in '.gz', '.bz2', '.zip', '.xz', or '.zst', respectively.

The compression parameter can also be a dict in order to pass options to the compression protocol. It must have a 'method' key set to the name of the compression protocol, which must be one of {'zip', 'gzip', 'bz2', 'xz', 'zstd'}. All other key-value pairs are passed to the underlying compression library.

```
In [383]: df = pd.DataFrame(
.....:     {
```

(continues on next page)

(continued from previous page)

```
....:     "A": np.random.randn(1000),
....:     "B": "foo",
....:     "C": pd.date_range("20130101", periods=1000, freq="s"),
....:   }
....: )
....:
```

In [384]: df**Out[384]:**

	A	B	C
0	-0.288267	foo	2013-01-01 00:00:00
1	-0.084905	foo	2013-01-01 00:00:01

999 -1.197988
Name: A, Length: 1000, dtype: float64

```

Passing options to the compression protocol in order to speed up compression:

```
In [397]: df.to_pickle("data.pkl.gz", compression={"method": "gzip", "compresslevel": 1})
```

2.4.11 msgpack

pandas support for msgpack has been removed in version 1.0.0. It is recommended to use [pickle](#) instead.

Alternatively, you can also use the Arrow IPC serialization format for on-the-wire transmission of pandas objects. For documentation on pyarrow, see [here](#).

2.4.12 HDF5 (PyTables)

HDFStore is a dict-like object which reads and writes pandas using the high performance HDF5 format using the excellent [PyTables](#) library. See the [cookbook](#) for some advanced strategies

Warning: pandas uses PyTables for reading and writing HDF5 files, which allows serializing object-dtype data with pickle. Loading pickled data received from untrusted sources can be unsafe.

See: <https://docs.python.org/3/library/pickle.html> for more.

```
In [398]: store = pd.HDFStore("store.h5")
```

```
In [399]: print(store)
<class 'pandas.io.pytables.HDFStore'>
File path: store.h5
```

Objects can be written to the file just like adding key-value pairs to a dict:

```
In [400]: index = pd.date_range("1/1/2000", periods=8)
```

```
In [401]: s = pd.Series(np.random.randn(5), index=["a", "b", "c", "d", "e"])
```

```
In [402]: df = pd.DataFrame(np.random.randn(8, 3), index=index, columns=["A", "B", "C"])
```

store.put('s', s) is an equivalent method

```
In [403]: store["s"] = s
```

```
In [404]: store["df"] = df
```

```
In [405]: store
```

(continues on next page)

(continued from previous page)

Out[405]:

```
<class 'pandas.io.pytables.HDFStore'>
File path: store.h5
```

In a current or later Python session, you can retrieve stored objects:

```
# store.get('df') is an equivalent method
In [406]: store["df"]
Out[406]:
          A         B         C
2000-01-01  1.334065  0.521036  0.930384
2000-01-02 -1.613932  1.088104 -0.632963
2000-01-03 -0.585314 -0.275038 -0.937512
2000-01-04  0.632369 -1.249657  0.975593
2000-01-05  1.060617 -0.143682  0.218423
2000-01-06  3.050329  1.317933 -0.963725
2000-01-07 -0.539452 -0.771133  0.023751
2000-01-08  0.649464 -1.736427  0.197288

# dotted (attribute) access provides get as well
In [407]: store.df
Out[407]:
          A         B         C
2000-01-01  1.334065  0.521036  0.930384
2000-01-02 -1.613932  1.088104 -0.632963
2000-01-03 -0.585314 -0.275038 -0.937512
2000-01-04  0.632369 -1.249657  0.975593
2000-01-05  1.060617 -0.143682  0.218423
2000-01-06  3.050329  1.317933 -0.963725
2000-01-07 -0.539452 -0.771133  0.023751
2000-01-08  0.649464 -1.736427  0.197288
```

Deletion of the object specified by the key:

```
# store.remove('df') is an equivalent method
In [408]: del store["df"]

In [409]: store
Out[409]:
<class 'pandas.io.pytables.HDFStore'>
File path: store.h5
```

Closing a Store and using a context manager:

```
In [410]: store.close()

In [411]: store
Out[411]:
<class 'pandas.io.pytables.HDFStore'>
File path: store.h5

In [412]: store.is_open
Out[412]: False
```

(continues on next page)

(continued from previous page)

```
# Working with, and automatically closing the store using a context manager
In [413]: with pd.HDFStore("store.h5") as store:
...:     store.keys()
...:
```

Read/write API

HDFStore supports a top-level API using `read_hdf` for reading and `to_hdf` for writing, similar to how `read_csv` and `to_csv` work.

```
In [414]: df_t1 = pd.DataFrame({ "A": list(range(5)), "B": list(range(5)) })
In [415]: df_t1.to_hdf("store_t1.h5", "table", append=True)
In [416]: pd.read_hdf("store_t1.h5", "table", where=["index>2"])
Out[416]:
   A   B
3  3  3
4  4  4
```

HDFStore will by default not drop rows that are all missing. This behavior can be changed by setting `dropna=True`.

```
In [417]: df_with_missing = pd.DataFrame(
...:     {
...:         "col1": [0, np.nan, 2],
...:         "col2": [1, np.nan, np.nan],
...:     }
...: )
...:

In [418]: df_with_missing
Out[418]:
   col1  col2
0    0.0   1.0
1    NaN   NaN
2    2.0   NaN

In [419]: df_with_missing.to_hdf("file.h5", "df_with_missing", format="table", mode="w")

In [420]: pd.read_hdf("file.h5", "df_with_missing")
Out[420]:
   col1  col2
0    0.0   1.0
1    NaN   NaN
2    2.0   NaN

In [421]: df_with_missing.to_hdf(
...:     "file.h5", "df_with_missing", format="table", mode="w", dropna=True
...: )
...:
```

(continues on next page)

(continued from previous page)

```
In [422]: pd.read_hdf("file.h5", "df_with_missing")
Out[422]:
   col1  col2
0    0.0   1.0
2    2.0   NaN
```

Fixed format

The examples above show storing using `put`, which write the HDF5 to PyTables in a fixed array format, called the `fixed` format. These types of stores are **not** appendable once written (though you can simply remove them and rewrite). Nor are they `queryable`; they must be retrieved in their entirety. They also do not support dataframes with non-unique column names. The `fixed` format stores offer very fast writing and slightly faster reading than `table` stores. This format is specified by default when using `put` or `to_hdf` or by `format='fixed'` or `format='f'`.

Warning: A fixed format will raise a `TypeError` if you try to retrieve using a `where`:

```
>>> pd.DataFrame(np.random.randn(10, 2)).to_hdf("test_fixed.h5", "df")
>>> pd.read_hdf("test_fixed.h5", "df", where="index>5")
TypeError: cannot pass a where specification when reading a fixed format.
         this store must be selected in its entirety
```

Table format

HDFStore supports another PyTables format on disk, the `table` format. Conceptually a `table` is shaped very much like a DataFrame, with rows and columns. A `table` may be appended to in the same or other sessions. In addition, delete and query type operations are supported. This format is specified by `format='table'` or `format='t'` to append or `put` or `to_hdf`.

This format can be set as an option as well `pd.set_option('io.hdf.default_format', 'table')` to enable `put`/`append`/`to_hdf` to by default store in the `table` format.

```
In [423]: store = pd.HDFStore("store.h5")

In [424]: df1 = df[0:4]

In [425]: df2 = df[4:]

# append data (creates a table automatically)
In [426]: store.append("df", df1)

In [427]: store.append("df", df2)

In [428]: store
Out[428]:
<class 'pandas.io.pytables.HDFStore'>
File path: store.h5

# select the entire object
```

(continues on next page)

(continued from previous page)

```
In [429]: store.select("df")
Out[429]:
          A         B         C

# the type of stored data
In [430]: store.root.df._v_attrs.pandas_type
Out[430]: 'frame_table'
```

Note: You can also create a `Table` by passing `format='table'` or `format='t'` to a `put` operation.

Hierarchical keys

Keys to a store can be specified as a string. These can be in a hierarchical path-name like `format` (e.g. `foo/bar/bah`), which will generate a hierarchy of sub-stores (or Groups in PyTables parlance). Keys can be specified without the leading `'/'` and are **always** absolute (e.g. `'foo'` refers to `'/foo'`). Removal operations can remove everything in the sub-store and **below**, so be *careful*.

```
In [431]: store.put("foo/bar/bah", df)

In [432]: store.append("food/orange", df)

In [433]: store.append("food/apple", df)

In [434]: store
Out[434]:
<class 'pandas.io.pytables.HDFStore'>
File path: store.h5

# a list of keys are returned
In [435]: store.keys()
Out[435]: ['/df', '/food/apple', '/food/orange', '/foo/bar/bah']

# remove all nodes under this level
In [436]: store.remove("food")

In [437]: store
Out[437]:
<class 'pandas.io.pytables.HDFStore'>
File path: store.h5
```

You can walk through the group hierarchy using the `walk` method which will yield a tuple for each group key along with the relative keys of its contents.

```
In [438]: for (path, subgroups, subkeys) in store.walk():
    ....:     for subgroup in subgroups:
    ....:         print("GROUP: {}{}".format(path, subgroup))
    ....:     for subkey in subkeys:
    ....:         key = "/".join([path, subkey])
    ....:         print("KEY: {}".format(key))
    ....:         print(store.get(key))

GROUP: /foo
KEY: /df
      A          B          C
2000-01-01  1.334065  0.521036  0.930384
2000-01-02 -1.613932  1.088104 -0.632963
2000-01-03 -0.585314 -0.275038 -0.937512
2000-01-04  0.632369 -1.249657  0.975593
2000-01-05  1.060617 -0.143682  0.218423
2000-01-06  3.050329  1.317933 -0.963725
2000-01-07 -0.539452 -0.771133  0.023751
2000-01-08  0.649464 -1.736427  0.197288

GROUP: /foo/bar
KEY: /foo/bar/bah
      A          B          C
2000-01-01  1.334065  0.521036  0.930384
2000-01-02 -1.613932  1.088104 -0.632963
2000-01-03 -0.585314 -0.275038 -0.937512

2000-01-05  1.060617 -0.143682  0.218423
2000-01-06  3.050329  1.317933 -0.963725
2000-01-07 -0.539452 -0.771133  0.023751
2000-01-08  0.649464 -1.736427  0.197288
```

Warning: Hierarchical keys cannot be retrieved as dotted (attribute) access as described above for items stored under the root node.

```
In [8]: store.foo.bar.bah
AttributeError: 'HDFStore' object has no attribute 'foo'

# you can directly access the actual PyTables node but using the root node
In [9]: store.root.foo.bar.bah
Out[9]:
/foobar/bah (Group)
  children := ['block0_items' (Array), 'block0_values' (Array), 'axis0' (Array),
  ↗ 'axis1' (Array)]
```

Instead, use explicit string based keys:

```
In [439]: store["foo/bar/bah"]
Out[439]:
      A          B          C
2000-01-01  1.334065  0.521036  0.930384
2000-01-02 -1.613932  1.088104 -0.632963
2000-01-03 -0.585314 -0.275038 -0.937512
2000-01-04  0.632369 -1.249657  0.975593
2000-01-05  1.060617 -0.143682  0.218423
2000-01-06  3.050329  1.317933 -0.963725
2000-01-07 -0.539452 -0.771133  0.023751
2000-01-08  0.649464 -1.736427  0.197288
```

Storing types

Storing mixed types in a table

Storing mixed-dtype data is supported. Strings are stored as a fixed-width using the maximum size of the appended column. Subsequent attempts at appending longer strings will raise a `ValueError`.

Passing `min_itemsize={`values`: size}` as a parameter to append will set a larger minimum for the string columns. Storing floats, strings, ints, bools, `datetime64` are currently supported. For string columns, passing `nan_rep = 'nan'` to append will change the default nan representation on disk (which converts to/from `np.nan`), this defaults to `nan`.

```
In [440]: df_mixed = pd.DataFrame(
    ....:
    ....:     {
    ....:         "A": np.random.randn(8),
    ....:         "B": np.random.randn(8),
    ....:         "C": np.array(np.random.randn(8), dtype="float32"),
    ....:         "string": "string",
    ....:         "int": 1,
    ....:         "bool": True,
    ....:         "datetime64": pd.Timestamp("20010102"),
    ....:     },
    ....:     index=list(range(8)),
    ....: )
....:
```

```
In [441]: df_mixed.loc[df_mixed.index[3:5], ["A", "B", "string", "datetime64"]] = np.nan
```

```
In [442]: store.append("df_mixed", df_mixed, min_itemsize={"values": 50})
```

```
In [443]: df_mixed1 = store.select("df_mixed")
```

```
In [444]: df_mixed1
```

```
Out[444]:
      A          B          C  string  int  bool  datetime64
0 -0.116008  0.743946 -0.398501  string    1  True  2001-01-02

```

Storing MultiIndex DataFrames

Storing MultiIndex DataFrames as tables is very similar to storing/selecting from homogeneous index DataFrames.

```

In [447]: index = pd.MultiIndex(
    ....:     levels=[["foo", "bar", "baz", "qux"], ["one", "two", "three"]],
    ....:     codes=[[0, 0, 0, 1, 1, 2, 2, 3, 3], [0, 1, 2, 0, 1, 1, 2, 0, 1, 2]],
    ....:     names=["foo", "bar"],
    ....: )
    ....:

In [448]: df_mi = pd.DataFrame(np.random.randn(10, 3), index=index, columns=["A", "B", "C"])
           ↵

In [449]: df_mi
Out[449]:
          A         B         C
foo bar
foo one   0.667450  0.169405 -1.358046
        two   -0.105563  0.492195  0.076693
        three   0.213685 -0.285283 -1.210529
bar one   -1.408386  0.941577 -0.342447
        two   0.222031  0.052607  2.093214
baz two   1.064908  1.778161 -0.913867
        three  -0.030004 -0.399846 -1.234765
qux one   0.081323 -0.268494  0.168016
        two   -0.898283 -0.218499  1.408028
        three  -1.267828 -0.689263  0.520995

```

(continues on next page)

(continued from previous page)

```
In [450]: store.append("df_mi", df_mi)
```

```
In [451]: store.select("df_mi")
```

```
Out[451]:
```

	A	B	C
foo bar			
foo one	0.667450	0.169405	-1.358046
two	-0.105563	0.492195	0.076693
three	0.213685	-0.285283	-1.210529
bar one	-1.408386	0.941577	-0.342447
two	0.222031	0.052607	2.093214
baz two	1.064908	1.778161	-0.913867
three	-0.030004	-0.399846	-1.234765
qux one	0.081323	-0.268494	0.168016
two	-0.898283	-0.218499	1.408028
three	-1.267828	-0.689263	0.520995

```
# the levels are automatically included as data columns
```

```
In [452]: store.select("df_mi", "foo=bar")
```

```
Out[452]:
```

	A	B	C
foo bar			
bar one	-1.408386	0.941577	-0.342447
two	0.222031	0.052607	2.093214

Note: The `index` keyword is reserved and cannot be used as a level name.

Querying

Querying a table

`select` and `delete` operations have an optional criterion that can be specified to select/delete only a subset of the data. This allows one to have a very large on-disk table and retrieve only a portion of the data.

A query is specified using the `Term` class under the hood, as a boolean expression.

- `index` and `columns` are supported indexers of `DataFrames`.
- if `data_columns` are specified, these can be used as additional indexers.
- level name in a MultiIndex, with default name `level_0`, `level_1`, ... if not provided.

Valid comparison operators are:

`=`, `==`, `!=`, `>`, `>=`, `<`, `<=`

Valid boolean expressions are combined with:

- `|` : or
- `&` : and
- `(` and `)` : for grouping

These rules are similar to how boolean expressions are used in pandas for indexing.

Note:

- = will be automatically expanded to the comparison operator ==
- ~ is the not operator, but can only be used in very limited circumstances
- If a list/tuple of expressions is passed they will be combined via &

The following are valid expressions:

- 'index >= date'
- "columns = ['A', 'D']"
- "columns in ['A', 'D']"
- 'columns = A'
- 'columns == A'
- "~(columns = ['A', 'B'])"
- 'index > df.index[3] & string = "bar"'
- '(index > df.index[3] & index <= df.index[6]) | string = "bar"'
- "ts >= Timestamp('2012-02-01')"
- "major_axis>=20130101"

The indexers are on the left-hand side of the sub-expression:

columns, major_axis, ts

The right-hand side of the sub-expression (after a comparison operator) can be:

- functions that will be evaluated, e.g. `Timestamp('2012-02-01')`
- strings, e.g. "bar"
- date-like, e.g. 20130101, or "20130101"
- lists, e.g. "['A', 'B']"
- variables that are defined in the local names space, e.g. `date`

Note: Passing a string to a query by interpolating it into the query expression is not recommended. Simply assign the string of interest to a variable and use that variable in an expression. For example, do this

```
string = "HolyMoly"
store.select("df", "index == string")
```

instead of this

```
string = "HolyMoly"
store.select('df', f'index == {string}')
```

The latter will **not** work and will raise a `SyntaxError`. Note that there's a single quote followed by a double quote in the `string` variable.

If you *must* interpolate, use the `'%r'` format specifier

```
store.select("df", "index == %r" % string)
```

which will quote `string`.

Here are some examples:

```
In [453]: dfq = pd.DataFrame(  
.....:     np.random.randn(10, 4),  
.....:     columns=list("ABCD"),  
.....:     index=pd.date_range("20130101", periods=10),  
.....: )  
.....:
```

```
In [454]: store.append("dfq", dfq, format="table", data_columns=True)
```

Use boolean expressions, with in-line function evaluation.

```
In [455]: store.select("dfq", "index>pd.Timestamp('20130104') & columns=['A', 'B'])  
Out[455]:
```

	A	B
2013-01-05	-1.083889	0.811865
2013-01-06	-0.402227	1.618922
2013-01-07	0.948196	0.183573
2013-01-08	-1.043530	-0.708145
2013-01-09	0.813949	1.508891
2013-01-10	1.176488	-1.246093

Use inline column reference.

```
In [456]: store.select("dfq", where="A>0 or C>0")  
Out[456]:
```

	A	B	C	D
2013-01-01	0.620028	0.159416	-0.263043	-0.639244
2013-01-04	-0.536722	1.005707	0.296917	0.139796
2013-01-05	-1.083889	0.811865	1.648435	-0.164377
2013-01-07	0.948196	0.183573	0.145277	0.308146
2013-01-08	-1.043530	-0.708145	1.430905	-0.850136
2013-01-09	0.813949	1.508891	-1.556154	0.187597
2013-01-10	1.176488	-1.246093	-0.002726	-0.444249

The `columns` keyword can be supplied to select a list of columns to be returned, this is equivalent to passing a '`columns=list_of_columns_to_filter`':

```
In [457]: store.select("df", "columns=['A', 'B'])  
Out[457]:
```

	A	B
2000-01-01	1.334065	0.521036
2000-01-02	-1.613932	1.088104
2000-01-03	-0.585314	-0.275038
2000-01-04	0.632369	-1.249657
2000-01-05	1.060617	-0.143682
2000-01-06	3.050329	1.317933

(continues on next page)

(continued from previous page)

```
2000-01-07 -0.539452 -0.771133
2000-01-08  0.649464 -1.736427
```

start and stop parameters can be specified to limit the total search space. These are in terms of the total number of rows in a table.

Note: select will raise a ValueError if the query expression has an unknown variable reference. Usually this means that you are trying to select on a column that is **not** a data_column.

select will raise a SyntaxError if the query expression is not valid.

Query timedelta64[ns]

You can store and query using the timedelta64[ns] type. Terms can be specified in the format: <float>(<unit>), where float may be signed (and fractional), and unit can be D, s, ms, us, ns for the timedelta. Here's an example:

```
In [458]: from datetime import timedelta

In [459]: dftd = pd.DataFrame(
...:     {
...:         "A": pd.Timestamp("20130101"),
...:         "B": [
...:             pd.Timestamp("20130101") + timedelta(days=i, seconds=10)
...:             for i in range(10)
...:         ],
...:     }
...: )
```

```
In [460]: dftd["C"] = dftd["A"] - dftd["B"]
```

```
In [461]: dftd
Out[461]:
      A            B            C
0 2013-01-01 2013-01-01 00:00:10 -1 days +23:59:50
1 2013-01-01 2013-01-02 00:00:10 -2 days +23:59:50
2 2013-01-01 2013-01-03 00:00:10 -3 days +23:59:50

```

Query MultiIndex

Selecting from a MultiIndex can be achieved by using the name of the level.

```
In [464]: df_mi.index.names
Out[464]: FrozenList(['foo', 'bar'])

In [465]: store.select("df_mi", "foo=bar and bar=two")
Out[465]:
          A           B           C
foo bar
baz two  1.064908  1.778161 -0.913867
```

If the MultiIndex levels names are `None`, the levels are automatically made available via the `level_n` keyword with `n` the level of the MultiIndex you want to select from.

```
In [466]: index = pd.MultiIndex(
    ....:     levels=[["foo", "bar", "baz", "qux"], ["one", "two", "three"]],
    ....:     codes=[[0, 0, 0, 1, 1, 2, 2, 3, 3], [0, 1, 2, 0, 1, 1, 2, 0, 1, 2]],
    ....: )
    ....:

In [467]: df_mi_2 = pd.DataFrame(np.random.randn(10, 3), index=index, columns=["A", "B",
   ....: "C"])

In [468]: df_mi_2
Out[468]:
          A           B           C
foo one  0.856838  1.491776  0.001283
      two  0.701816 -1.097917  0.102588
      three 0.661740  0.443531  0.559313
bar one -0.459055 -1.222598 -0.455304
      two -0.781163  0.826204 -0.530057
baz two  0.296135  1.366810  1.073372
      three -0.994957  0.755314  2.119746
qux one -2.628174 -0.089460 -0.133636
      two  0.337920 -0.634027  0.421107
      three 0.604303  1.053434  1.109090

In [469]: store.append("df_mi_2", df_mi_2)

# the levels are automatically included as data columns with keyword level_n
In [470]: store.select("df_mi_2", "level_0=foo and level_1=two")
Out[470]:
```

(continues on next page)

(continued from previous page)

	A	B	C
foo two	0.701816	-1.097917	0.102588

Indexing

You can create/modify an index for a table with `create_table_index` after data is already in the table (after and `append/put` operation). Creating a table index is **highly** encouraged. This will speed your queries a great deal when you use a `select` with the indexed dimension as the `where`.

Note: Indexes are automagically created on the indexables and any data columns you specify. This behavior can be turned off by passing `index=False` to `append`.

```
# we have automagically already created an index (in the first section)
In [471]: i = store.root.df.table.cols.index.index

In [472]: i.optlevel, i.kind
Out[472]: (6, 'medium')

# change an index by passing new parameters
In [473]: store.create_table_index("df", optlevel=9, kind="full")

In [474]: i = store.root.df.table.cols.index.index

In [475]: i.optlevel, i.kind
Out[475]: (9, 'full')
```

Oftentimes when appending large amounts of data to a store, it is useful to turn off index creation for each append, then recreate at the end.

```
In [476]: df_1 = pd.DataFrame(np.random.randn(10, 2), columns=list("AB"))

In [477]: df_2 = pd.DataFrame(np.random.randn(10, 2), columns=list("AB"))

In [478]: st = pd.HDFStore("appends.h5", mode="w")

In [479]: st.append("df", df_1, data_columns=["B"], index=False)

In [480]: st.append("df", df_2, data_columns=["B"], index=False)

In [481]: st.get_storer("df").table
Out[481]:
/df/table (Table(20,))
  description := {
    "index": Int64Col(shape=(), dflt=0, pos=0),
    "values_block_0": Float64Col(shape=(1,), dflt=0.0, pos=1),
    "B": Float64Col(shape=(), dflt=0.0, pos=2)}
  byteorder := 'little'
  chunkshape := (2730,)
```

Then create the index when finished appending.

```
In [482]: st.create_table_index("df", columns=["B"], optlevel=9, kind="full")
```

```
In [483]: st.get_storer("df").table
```

```
Out[483]:
```

```
/df/table (Table(20,)) ''
description := {
    "index": Int64Col(shape=(), dfilt=0, pos=0),
    "values_block_0": Float64Col(shape=(1,), dfilt=0.0, pos=1),
    "B": Float64Col(shape=(), dfilt=0.0, pos=2)}
byteorder := 'little'
chunkshape := (2730,)
autoindex := True
colindexes := {
    "B": Index(9, fullshuffle, zlib(1)).is_csi=True}
```

```
In [484]: st.close()
```

See [here](#) for how to create a completely-sorted-index (CSI) on an existing store.

Query via data columns

You can designate (and index) certain columns that you want to be able to perform queries (other than the `indexable` columns, which you can always query). For instance say you want to perform this common operation, on-disk, and return just the frame that matches this query. You can specify `data_columns = True` to force all columns to be `data_columns`.

```
In [485]: df_dc = df.copy()
```

```
In [486]: df_dc["string"] = "foo"
```

```
In [487]: df_dc.loc[df_dc.index[4:6], "string"] = np.nan
```

```
In [488]: df_dc.loc[df_dc.index[7:9], "string"] = "bar"
```

```
In [489]: df_dc["string2"] = "cool"
```

```
In [490]: df_dc.loc[df_dc.index[1:3], ["B", "C"]] = 1.0
```

```
In [491]: df_dc
```

```
Out[491]:
```

	A	B	C	string	string2
2000-01-01	1.334065	0.521036	0.930384	foo	cool
2000-01-02	-1.613932	1.000000	1.000000	foo	cool

# this is in-memory version of this type of selection
In [495]: df_dc[(df_dc.B > 0) & (df_dc.C > 0) & (df_dc.string == "foo")]
Out[495]:
          A           B           C string string2
2000-01-01  1.334065  0.521036  0.930384    foo    cool
2000-01-02 -1.613932  1.000000  1.000000    foo    cool
2000-01-03 -0.585314  1.000000  1.000000    foo    cool

# we have automagically created this index and the B/C/string/string2
# columns are stored separately as ``PyTables`` columns
In [496]: store.root.df_dc.table
Out[496]:
/df_dc/table (Table(8,)) ''
description := {
    "index": Int64Col(shape=(), dflt=0, pos=0),
    "values_block_0": Float64Col(shape=(1,), dflt=0.0, pos=1),
    "B": Float64Col(shape=(), dflt=0.0, pos=2),
    "C": Float64Col(shape=(), dflt=0.0, pos=3),
    "string": StringCol(itemsize=3, shape=(), dflt=b'', pos=4),
    "string2": StringCol(itemsize=4, shape=(), dflt=b'', pos=5)}
byteorder := 'little'
chunkshape := (1680,)
autoindex := True
colindexes := {
    "index": Index(6, mediumshuffle, zlib(1)).is_csi=False,
    "B": Index(6, mediumshuffle, zlib(1)).is_csi=False,
    "C": Index(6, mediumshuffle, zlib(1)).is_csi=False,
    "string": Index(6, mediumshuffle, zlib(1)).is_csi=False,
    "string2": Index(6, mediumshuffle, zlib(1)).is_csi=False}
```

There is some performance degradation by making lots of columns into `data columns`, so it is up to the user to designate these. In addition, you cannot change data columns (nor indexables) after the first append/put operation (Of course you can simply read in the data and create a new table!).

Iterator

You can pass `iterator=True` or `chunksize=number_in_a_chunk` to `select` and `select_as_multiple` to return an iterator on the results. The default is 50,000 rows returned in a chunk.

```
In [497]: for df in store.select("df", chunksize=3):
    ....:     print(df)
    ....:
        A          B          C
2000-01-01  1.334065  0.521036  0.930384
2000-01-02 -1.613932  1.088104 -0.632963
2000-01-03 -0.585314 -0.275038 -0.937512
        A          B          C
2000-01-04  0.632369 -1.249657  0.975593
2000-01-05  1.060617 -0.143682  0.218423
2000-01-06  3.050329  1.317933 -0.963725
        A          B          C
2000-01-07 -0.539452 -0.771133  0.023751
2000-01-08  0.649464 -1.736427  0.197288
```

Note: You can also use the iterator with `read_hdf` which will open, then automatically close the store when finished iterating.

```
for df in pd.read_hdf("store.h5", "df", chunksize=3):
    print(df)
```

Note, that the `chunksize` keyword applies to the **source** rows. So if you are doing a query, then the `chunksize` will subdivide the total rows in the table and the query applied, returning an iterator on potentially unequal sized chunks.

Here is a recipe for generating a query and using it to create equal sized return chunks.

```
In [498]: dfeq = pd.DataFrame({"number": np.arange(1, 11)})
```

```
In [499]: dfeq
```

```
Out[499]:
```

```
   number
0       1
1       2
2       3
3       4
4       5
5       6
6       7
7       8
8       9
9      10
```

```
In [500]: store.append("dfeq", dfeq, data_columns=["number"])
```

```
In [501]: def chunks(l, n):
```

```
    ....:     return [l[i: i + n] for i in range(0, len(l), n)]
    ....:
```

(continues on next page)

(continued from previous page)

```
In [502]: evens = [2, 4, 6, 8, 10]

In [503]: coordinates = store.select_as_coordinates("dfeq", "number=evens")

In [504]: for c in chunks(coordinates, 2):
.....:     print(store.select("dfeq", where=c))
.....:
    number
1      2
3      4
    number
5      6
7      8
    number
9      10
```

Advanced queries

Select a single column

To retrieve a single indexable or data column, use the method `select_column`. This will, for example, enable you to get the index very quickly. These return a `Series` of the result, indexed by the row number. These do not currently accept the `where` selector.

```
In [505]: store.select_column("df_dc", "index")
Out[505]:
0    2000-01-01
1    2000-01-02
2    2000-01-03
3    2000-01-04
4    2000-01-05
5    2000-01-06
6    2000-01-07
7    2000-01-08
Name: index, dtype: datetime64[ns]

In [506]: store.select_column("df_dc", "string")
Out[506]:
0    foo
1    foo
2    foo
3    foo
4    NaN
5    NaN
6    foo
7    bar
Name: string, dtype: object
```

Selecting coordinates

Sometimes you want to get the coordinates (a.k.a the index locations) of your query. This returns an Int64Index of the resulting locations. These coordinates can also be passed to subsequent where operations.

```
In [507]: df_coord = pd.DataFrame(  
.....:     np.random.randn(1000, 2), index=pd.date_range("20000101", periods=1000)  
.....: )  
.....:  
  
In [508]: store.append("df_coord", df_coord)  
  
In [509]: c = store.select_as_coordinates("df_coord", "index > 20020101")  
  
In [510]: c  
Out[510]:  
Int64Index([732, 733, 734, 735, 736, 737, 738, 739, 740, 741,  
...  
         990, 991, 992, 993, 994, 995, 996, 997, 998, 999],  
        dtype='int64', length=268)  
  
In [511]: store.select("df_coord", where=c)  
Out[511]:  
          0           1  
2002-01-02 -0.165548  0.646989  
2002-01-03  0.782753 -0.123409  
2002-01-04 -0.391932 -0.740915  
2002-01-05  1.211070 -0.668715  
2002-01-06  0.341987 -0.685867  
...  
          ...       ...  
2002-09-22  1.788110 -0.405908  
2002-09-23 -0.801912  0.768460  
2002-09-24  0.466284 -0.457411  
2002-09-25 -0.364060  0.785367  
2002-09-26 -1.463093  1.187315  
  
[268 rows x 2 columns]
```

Selecting using a where mask

Sometime your query can involve creating a list of rows to select. Usually this mask would be a resulting index from an indexing operation. This example selects the months of a datetimeindex which are 5.

```
In [512]: df_mask = pd.DataFrame(  
.....:     np.random.randn(1000, 2), index=pd.date_range("20000101", periods=1000)  
.....: )  
.....:  
  
In [513]: store.append("df_mask", df_mask)  
  
In [514]: c = store.select_column("df_mask", "index")
```

(continues on next page)

(continued from previous page)

```
In [515]: where = c[pd.DatetimeIndex(c).month == 5].index
```

```
In [516]: store.select("df_mask", where=where)
```

```
Out[516]:
```

	0	1
2000-05-01	1.735883	-2.615261
2000-05-02	0.422173	2.425154
2000-05-03	0.632453	-0.165640
2000-05-04	-1.017207	-0.005696
2000-05-05	0.299606	0.070606
...
2002-05-27	0.234503	1.199126
2002-05-28	-3.021833	-1.016828
2002-05-29	0.522794	0.063465
2002-05-30	-1.653736	0.031709
2002-05-31	-0.968402	-0.393583

```
[93 rows x 2 columns]
```

Storer object

If you want to inspect the stored object, retrieve via `get_storer`. You could use this programmatically to say get the number of rows in an object.

```
In [517]: store.get_storer("df_dc").nrows
```

```
Out[517]: 8
```

Multiple table queries

The methods `append_to_multiple` and `select_as_multiple` can perform appending/selecting from multiple tables at once. The idea is to have one table (call it the selector table) that you index most/all of the columns, and perform your queries. The other table(s) are data tables with an index matching the selector table's index. You can then perform a very fast query on the selector table, yet get lots of data back. This method is similar to having a very wide table, but enables more efficient queries.

The `append_to_multiple` method splits a given single DataFrame into multiple tables according to `d`, a dictionary that maps the table names to a list of 'columns' you want in that table. If `None` is used in place of a list, that table will have the remaining unspecified columns of the given DataFrame. The argument `selector` defines which table is the selector table (which you can make queries from). The argument `dropna` will drop rows from the input DataFrame to ensure tables are synchronized. This means that if a row for one of the tables being written to is entirely `np.NaN`, that row will be dropped from all tables.

If `dropna` is False, **THE USER IS RESPONSIBLE FOR SYNCHRONIZING THE TABLES**. Remember that entirely `np.NaN` rows are not written to the HDFStore, so if you choose to call `dropna=False`, some tables may have more rows than others, and therefore `select_as_multiple` may not work or it may return unexpected results.

```
In [518]: df_mt = pd.DataFrame(
.....:     np.random.randn(8, 6),
.....:     index=pd.date_range("1/1/2000", periods=8),
.....:     columns=["A", "B", "C", "D", "E", "F"],
```

(continues on next page)

(continued from previous page)

```

....: )
....:

In [519]: df_mt["foo"] = "bar"

In [520]: df_mt.loc[df_mt.index[1], ("A", "B")] = np.nan

# you can also create the tables individually
In [521]: store.append_to_multiple(
....:     {"df1_mt": ["A", "B"], "df2_mt": None}, df_mt, selector="df1_mt"
....: )
....:

In [522]: store
Out[522]:

Delete from a table

You can delete from a table selectively by specifying a `where`. In deleting rows, it is important to understand the PyTables deletes rows by erasing the rows, then **moving** the following data. Thus deleting can potentially be a very expensive operation depending on the orientation of your data. To get optimal performance, it's worthwhile to have the dimension you are deleting be the first of the `indexables`.

Data is ordered (on the disk) in terms of the `indexables`. Here's a simple use case. You store panel-type data, with dates in the `major_axis` and ids in the `minor_axis`. The data is then interleaved like this:

- `date_1`
 - `id_1`
 - `id_2`
 - `.`
 - `id_n`
- `date_2`
 - `id_1`
 - `.`
 - `id_n`

It should be clear that a delete operation on the `major_axis` will be fairly quick, as one chunk is removed, then the following data moved. On the other hand a delete operation on the `minor_axis` will be very expensive. In this case it would almost certainly be faster to rewrite the table using a `where` that selects all but the missing data.

Warning: Please note that HDF5 **DOES NOT RECLAIM SPACE** in the h5 files automatically. Thus, repeatedly deleting (or removing nodes) and adding again, **WILL TEND TO INCREASE THE FILE SIZE**.

To repack and clean the file, use `ptrepack`.

Notes & caveats

Compression

PyTables allows the stored data to be compressed. This applies to all kinds of stores, not just tables. Two parameters are used to control compression: `complevel` and `complib`.

- `complevel` specifies if and how hard data is to be compressed. `complevel=0` and `complevel=None` disables compression and `0<complevel<10` enables compression.
- `complib` specifies which compression library to use. If nothing is specified the default library `zlib` is used. A compression library usually optimizes for either good compression rates or speed and the results will depend on the type of data. Which type of compression to choose depends on your specific needs and data. The list of supported compression libraries:
 - `zlib`: The default compression library. A classic in terms of compression, achieves good compression rates but is somewhat slow.

- `lzo`: Fast compression and decompression.
- `bzip2`: Good compression rates.
- `blosc`: Fast compression and decompression.

Support for alternative blosc compressors:

- * `blosc:blosclz` This is the default compressor for `blosc`
- * `blosc:lz4`: A compact, very popular and fast compressor.
- * `blosc:lz4hc`: A tweaked version of LZ4, produces better compression ratios at the expense of speed.
- * `blosc:snappy`: A popular compressor used in many places.
- * `blosc:zlib`: A classic; somewhat slower than the previous ones, but achieving better compression ratios.
- * `blosc:zstd`: An extremely well balanced codec; it provides the best compression ratios among the others above, and at reasonably fast speed.

If `complib` is defined as something other than the listed libraries a `ValueError` exception is issued.

Note: If the library specified with the `complib` option is missing on your platform, compression defaults to `zlib` without further ado.

Enable compression for all objects within the file:

```
store_compressed = pd.HDFStore(  
    "store_compressed.h5", complevel=9, complib="blosc:blosclz"  
)
```

Or on-the-fly compression (this only applies to tables) in stores where compression is not enabled:

```
store.append("df", df, complib="zlib", complevel=5)
```

ptrepack

PyTables offers better write performance when tables are compressed after they are written, as opposed to turning on compression at the very beginning. You can use the supplied PyTables utility `ptrepack`. In addition, `ptrepack` can change compression levels after the fact.

```
ptrepack --chunkshape=auto --propindexes --complevel=9 --complib=blosc in.h5 out.h5
```

Furthermore `ptrepack in.h5 out.h5` will *repack* the file to allow you to reuse previously deleted space. Alternatively, one can simply remove the file and write again, or use the `copy` method.

Caveats

Warning: HDFStore is **not-threadsafe for writing**. The underlying PyTables only supports concurrent reads (via threading or processes). If you need reading and writing *at the same time*, you need to serialize these operations in a single thread in a single process. You will corrupt your data otherwise. See the ([GH2397](#)) for more information.

- If you use locks to manage write access between multiple processes, you may want to use `fsync()` before releasing write locks. For convenience you can use `store.flush(fsync=True)` to do this for you.
- Once a `table` is created columns (DataFrame) are fixed; only exactly the same columns can be appended
- Be aware that timezones (e.g., `pytz.timezone('US/Eastern')`) are not necessarily equal across timezone versions. So if data is localized to a specific timezone in the HDFStore using one version of a timezone library and that data is updated with another version, the data will be converted to UTC since these timezones are not considered equal. Either use the same version of timezone library or use `tz_convert` with the updated timezone definition.

Warning: PyTables will show a `NaturalNameWarning` if a column name cannot be used as an attribute selector. *Natural* identifiers contain only letters, numbers, and underscores, and may not begin with a number. Other identifiers cannot be used in a `where` clause and are generally a bad idea.

DataTypes

HDFStore will map an object dtype to the PyTables underlying dtype. This means the following types are known to work:

Type	Represents missing values
<code>floating : float64, float32, float16</code>	<code>np.nan</code>
<code>integer : int64, int32, int8, uint64, uint32, uint8</code>	
<code>boolean</code>	
<code>datetime64[ns]</code>	<code>NaT</code>
<code>timedelta64[ns]</code>	<code>NaT</code>
<code>categorical : see the section below</code>	
<code>object : strings</code>	<code>np.nan</code>

unicode columns are not supported, and **WILL FAIL**.

Categorical data

You can write data that contains `category` dtypes to a HDFStore. Queries work the same as if it was an object array. However, the `category` dtypes data is stored in a more efficient manner.

```
In [526]: dfcat = pd.DataFrame(
.....:     {"A": pd.Series(list("aabbcdba")), "B": np.random.
→randn(8)}
.....:
.....:
```

(continues on next page)

	A	category
	B	float64
		dtype: object

String columns

min_itemsize

The underlying implementation of `HDFStore` uses a fixed column width (`itemsize`) for string columns. A string column `itemsize` is calculated as the maximum of the length of data (for that column) that is passed to the `HDFStore`, **in the first append**. Subsequent appends, may introduce a string for a column **larger** than the column can hold, an Exception will be raised (otherwise you could have a silent truncation of these columns, leading to loss of information). In the future we may relax this and allow a user-specified truncation to occur.

Pass `min_itemsize` on the first table creation to a-priori specify the minimum length of a particular string column. `min_itemsize` can be an integer, or a dict mapping a column name to an integer. You can pass `values` as a key to allow all `indexables` or `data_columns` to have this `min_itemsize`.

Passing a `min_itemsize` dict will cause all passed columns to be created as `data_columns` automatically.

Note: If you are not passing any `data_columns`, then the `min_itemsize` will be the maximum of the length of any string passed

```
In [534]: dfs = pd.DataFrame({"A": "foo", "B": "bar"}, index=list(range(5)))
```

```
In [535]: dfs
```

```
Out[535]:
```

	A	B
0	foo	bar
1	foo	bar
2	foo	bar
3	foo	bar
4	foo	bar

A and B have a size of 30

```
In [536]: store.append("dfs", dfs, min_itemsize=30)
```

```
In [537]: store.get_storer("dfs").table
```

```
Out[537]:
```

```
/dfs/table (Table(5,)) ''
description := {
    "index": Int64Col(shape=(), dflt=0, pos=0),
    "values_block_0": StringCol(itemsize=30, shape=(2,), dflt=b'', pos=1)}
byteorder := 'little'
chunkshape := (963,)
autoindex := True
colindexes := {
    "index": Index(6, mediumshuffle, zlib(1)).is_csi=False}
```

A is created as a `data_column` with a size of 30

B is size is calculated

```
In [538]: store.append("dfs2", dfs, min_itemsize={"A": 30})
```

```
In [539]: store.get_storer("dfs2").table
```

```
Out[539]:
```

```
/dfs2/table (Table(5,)) ''
description := {
    "index": Int64Col(shape=(), dflt=0, pos=0),
    "values_block_0": StringCol(itemsize=3, shape=(1,), dflt=b'', pos=1),
    "A": StringCol(itemsize=30, shape=(), dflt=b'', pos=2)}
byteorder := 'little'
chunkshape := (1598,)
autoindex := True
colindexes := {
    "index": Index(6, mediumshuffle, zlib(1)).is_csi=False,
    "A": Index(6, mediumshuffle, zlib(1)).is_csi=False}
```

nan_rep

String columns will serialize a `np.nan` (a missing value) with the `nan_rep` string representation. This defaults to the string value `nan`. You could inadvertently turn an actual `nan` value into a missing value.

```
In [540]: dfss = pd.DataFrame({"A": ["foo", "bar", "nan"]})  
  
In [541]: dfss  
Out[541]:  
          A  
0    foo  
1    bar  
2    nan  
  
In [542]: store.append("dfss", dfss)  
  
In [543]: store.select("dfss")  
Out[543]:  
          A  
0    foo  
1    bar  
2    NaN  
  
# here you need to specify a different nan rep  
In [544]: store.append("dfss2", dfss, nan_rep="_nan_")  
  
In [545]: store.select("dfss2")  
Out[545]:  
          A  
0    foo  
1    bar  
2    nan
```

External compatibility

HDFStore writes `table` format objects in specific formats suitable for producing loss-less round trips to pandas objects. For external compatibility, HDFStore can read native PyTables format tables.

It is possible to write an HDFStore object that can easily be imported into R using the `rhd5` library ([Package website](#)). Create a table format store like this:

```
In [546]: df_for_r = pd.DataFrame(  
.....:     {  
.....:         "first": np.random.rand(100),  
.....:         "second": np.random.rand(100),  
.....:         "class": np.random.randint(0, 2, (100,)),  
.....:     },  
.....:     index=range(100),  
.....: )  
.....:  
  
In [547]: df_for_r.head()  
Out[547]:  
      first    second  class  
0  0.864919  0.852910      0  
1  0.030579  0.412962      1  
2  0.015226  0.978410      0
```

(continues on next page)

(continued from previous page)

```
3 0.498512 0.686761      0
4 0.232163 0.328185      1
```

In [548]: `store_export = pd.HDFStore("export.h5")`

In [549]: `store_export.append("df_for_r", df_for_r, data_columns=df_dc.columns)`

In [550]: `store_export`

Out[550]:

```
<class 'pandas.io.pytables.HDFStore'>
File path: export.h5
```

In R this file can be read into a `data.frame` object using the `rhdf5` library. The following example function reads the corresponding column names and data values from the values and assembles them into a `data.frame`:

```
# Load values and column names for all datasets from corresponding nodes and
# insert them into one data.frame object.

library(rhdf5)

loadhdf5data <- function(h5File) {

    listing <- h5ls(h5File)
    # Find all data nodes, values are stored in *_values and corresponding column
    # titles in *_items
    data_nodes <- grep("_values", listing$name)
    name_nodes <- grep("_items", listing$name)
    data_paths = paste(listing$group[data_nodes], listing$name[data_nodes], sep = "/")
    name_paths = paste(listing$group[name_nodes], listing$name[name_nodes], sep = "/")
    columns = list()
    for (idx in seq(data_paths)) {
        # NOTE: matrices returned by h5read have to be transposed to obtain
        # required Fortran order!
        data <- data.frame(t(h5read(h5File, data_paths[idx])))
        names <- t(h5read(h5File, name_paths[idx]))
        entry <- data.frame(data)
        colnames(entry) <- names
        columns <- append(columns, entry)
    }
    data <- data.frame(columns)

    return(data)
}
```

Now you can import the DataFrame into R:

```
> data = loadhdf5data("transfer.hdf5")
> head(data)
  first    second class
1 0.4170220047 0.3266449     0
2 0.7203244934 0.5270581     0
```

(continues on next page)

(continued from previous page)

3	0.0001143748	0.8859421	1
4	0.3023325726	0.3572698	1
5	0.1467558908	0.9085352	1
6	0.0923385948	0.6233601	1

Note: The R function lists the entire HDF5 file's contents and assembles the `data.frame` object from all matching nodes, so use this only as a starting point if you have stored multiple `DataFrame` objects to a single HDF5 file.

Performance

- tables format come with a writing performance penalty as compared to fixed stores. The benefit is the ability to append/delete and query (potentially very large amounts of data). Write times are generally longer as compared with regular stores. Query times can be quite fast, especially on an indexed axis.
- You can pass `chunksize=<int>` to `append`, specifying the write chunksize (default is 50000). This will significantly lower your memory usage on writing.
- You can pass `expectedrows=<int>` to the first `append`, to set the TOTAL number of rows that PyTables will expect. This will optimize read/write performance.
- Duplicate rows can be written to tables, but are filtered out in selection (with the last items being selected; thus a table is unique on major, minor pairs)
- A `PerformanceWarning` will be raised if you are attempting to store types that will be pickled by PyTables (rather than stored as endemic types). See [Here](#) for more information and some solutions.

2.4.13 Feather

Feather provides binary columnar serialization for data frames. It is designed to make reading and writing data frames efficient, and to make sharing data across data analysis languages easy.

Feather is designed to faithfully serialize and de-serialize `DataFrames`, supporting all of the pandas dtypes, including extension dtypes such as categorical and datetime with tz.

Several caveats:

- The format will NOT write an `Index`, or `MultiIndex` for the `DataFrame` and will raise an error if a non-default one is provided. You can `.reset_index()` to store the index or `.reset_index(drop=True)` to ignore it.
- Duplicate column names and non-string columns names are not supported
- Actual Python objects in object dtype columns are not supported. These will raise a helpful error message on an attempt at serialization.

See the [Full Documentation](#).

```
In [551]: df = pd.DataFrame(
.....:     {
.....:         "a": list("abc"),
.....:         "b": list(range(1, 4)),
.....:         "c": np.arange(3, 6).astype("u1"),
.....:         "d": np.arange(4.0, 7.0, dtype="float64"),
.....:         "e": [True, False, True],
```

(continues on next page)

(continued from previous page)

```

....:     "f": pd.Categorical(list("abc")),
....:     "g": pd.date_range("20130101", periods=3),
....:     "h": pd.date_range("20130101", periods=3, tz="US/Eastern"),
....:     "i": pd.date_range("20130101", periods=3, freq="ns"),
....:   }
....: )
....:

```

2.4.14 Parquet

Apache Parquet provides a partitioned binary columnar serialization for data frames. It is designed to make reading and writing data frames efficient, and to make sharing data across data analysis languages easy. Parquet can use a variety of compression techniques to shrink the file size as much as possible while still maintaining good read performance.

Parquet is designed to faithfully serialize and de-serialize `DataFrame`s, supporting all of the pandas dtypes, including extension dtypes such as `datetime` with `tz`.

Several caveats.

- Duplicate column names and non-string columns names are not supported.
- The `pyarrow` engine always writes the index to the output, but `fastparquet` only writes non-default indexes. This extra column can cause problems for non-pandas consumers that are not expecting it. You can force including or omitting indexes with the `index` argument, regardless of the underlying engine.
- Index level names, if specified, must be strings.
- In the `pyarrow` engine, categorical dtypes for non-string types can be serialized to parquet, but will de-serialize as their primitive dtype.
- The `pyarrow` engine preserves the `ordered` flag of categorical dtypes with string types. `fastparquet` does not preserve the `ordered` flag.
- Non supported types include `Interval` and actual Python object types. These will raise a helpful error message on an attempt at serialization. `Period` type is supported with `pyarrow >= 0.16.0`.
- The `pyarrow` engine preserves extension data types such as the nullable integer and string data type (requiring `pyarrow >= 0.16.0`, and requiring the extension type to implement the needed protocols, see the [extension types documentation](#)).

You can specify an engine to direct the serialization. This can be one of `pyarrow`, or `fastparquet`, or `auto`. If the engine is NOT specified, then the `pd.options.io.parquet.engine` option is checked; if this is also `auto`, then `pyarrow` is tried, and falling back to `fastparquet`.

See the documentation for `pyarrow` and `fastparquet`.

Note: These engines are very similar and should read/write nearly identical parquet format files. Currently `pyarrow` does not support `timedelta` data, `fastparquet>=0.1.4` supports timezone aware datetimes. These libraries differ by having different underlying dependencies (`fastparquet` by using `numba`, while `pyarrow` uses a c-library).

```
In [558]: df = pd.DataFrame(
...:     {
...:         "a": list("abc"),
...:         "b": list(range(1, 4)),
...:         "c": np.arange(3, 6).astype("u1"),
...:         "d": np.arange(4.0, 7.0, dtype="float64"),
...:         "e": [True, False, True],

dtype: object
```

Handling indexes

Serializing a DataFrame to parquet may include the implicit index as one or more columns in the output file. Thus, this code:

```
In [569]: df = pd.DataFrame({"a": [1, 2], "b": [3, 4]})
```

```
In [570]: df.to_parquet("test.parquet", engine="pyarrow")
```

creates a parquet file with *three* columns if you use pyarrow for serialization: a, b, and `__index_level_0__`. If you're using fastparquet, the index `may or may not` be written to the file.

This unexpected extra column causes some databases like Amazon Redshift to reject the file, because that column doesn't exist in the target table.

If you want to omit a dataframe's indexes when writing, pass `index=False` to `to_parquet()`:

```
In [571]: df.to_parquet("test.parquet", index=False)
```

This creates a parquet file with just the two expected columns, a and b. If your DataFrame has a custom index, you won't get it back when you load this file into a DataFrame.

Passing `index=True` will *always* write the index, even if that's not the underlying engine's default behavior.

Partitioning Parquet files

Parquet supports partitioning of data based on the values of one or more columns.

```
In [572]: df = pd.DataFrame({"a": [0, 0, 1, 1], "b": [0, 1, 0, 1]})
```

```
In [573]: df.to_parquet(path="test", engine="pyarrow", partition_cols=["a"], compression=None)
```

The path specifies the parent directory to which data will be saved. The `partition_cols` are the column names by which the dataset will be partitioned. Columns are partitioned in the order they are given. The partition splits are determined by the unique values in the partition columns. The above example creates a partitioned dataset that may look like:

```
test
└── a=0
    ├── 0bac803e32dc42ae83fddfd029cbdebc.parquet
    ...
    └── a=1
        ├── e6ab24a4f45147b49b54a662f0c412a3.parquet
        ...

```

2.4.15 ORC

New in version 1.0.0.

Similar to the [parquet](#) format, the [ORC Format](#) is a binary columnar serialization for data frames. It is designed to make reading data frames efficient. pandas provides *only* a reader for the ORC format, `read_orc()`. This requires the [pyarrow](#) library.

Warning:

- It is *highly recommended* to install pyarrow using conda due to some issues occurred by pyarrow.
- `read_orc()` is not supported on Windows yet, you can find valid environments on [install optional dependencies](#).

2.4.16 SQL queries

The `pandas.io.sql` module provides a collection of query wrappers to both facilitate data retrieval and to reduce dependency on DB-specific API. Database abstraction is provided by SQLAlchemy if installed. In addition you will need a driver library for your database. Examples of such drivers are `psycopg2` for PostgreSQL or `pymysql` for MySQL. For [SQLite](#) this is included in Python's standard library by default. You can find an overview of supported drivers for each SQL dialect in the [SQLAlchemy docs](#).

If SQLAlchemy is not installed, a fallback is only provided for sqlite (and for mysql for backwards compatibility, but this is deprecated and will be removed in a future version). This mode requires a Python database adapter which respect the [Python DB-API](#).

See also some [cookbook examples](#) for some advanced strategies.

The key functions are:

<code>read_sql_table(table_name, con[, schema, ...])</code>	Read SQL database table into a DataFrame.
<code>read_sql_query(sql, con[, index_col, ...])</code>	Read SQL query into a DataFrame.
<code>read_sql(sql, con[, index_col, ...])</code>	Read SQL query or database table into a DataFrame.
<code>DataFrame.to_sql(name, con[, schema, ...])</code>	Write records stored in a DataFrame to a SQL database.

Note: The function `read_sql()` is a convenience wrapper around `read_sql_table()` and `read_sql_query()` (and for backward compatibility) and will delegate to specific function depending on the provided input (database table name or sql query). Table names do not need to be quoted if they have special characters.

In the following example, we use the `SQLite` SQL database engine. You can use a temporary SQLite database where data are stored in “memory”.

To connect with SQLAlchemy you use the `create_engine()` function to create an engine object from database URI. You only need to create the engine once per database you are connecting to. For more information on `create_engine()` and the URI formatting, see the examples below and the SQLAlchemy documentation

```
In [574]: from sqlalchemy import create_engine  
  
# Create your engine.  
In [575]: engine = create_engine("sqlite:///:memory:")
```

If you want to manage your own connections you can pass one of those instead. The example below opens a connection to the database using a Python context manager that automatically closes the connection after the block has completed. See the [SQLAlchemy docs](#) for an explanation of how the database connection is handled.

```
with engine.connect() as conn, conn.begin():  
    data = pd.read_sql_table("data", conn)
```

Warning: When you open a connection to a database you are also responsible for closing it. Side effects of leaving a connection open may include locking the database or other breaking behaviour.

Writing DataFrames

Assuming the following data is in a `DataFrame` `data`, we can insert it into the database using `to_sql()`.

	id	Date	Col_1	Col_2	Col_3
0	26	2012-10-18	X	25.7	True
1	42	2012-10-19	Y	-12.4	False
2	63	2012-10-20	Z	5.73	True

```
In [576]: data  
Out[576]:  
      id      Date  Col_1  Col_2  Col_3  
0   26  2010-10-18     X  27.50   True  
1   42  2010-10-19     Y -12.50  False  
2   63  2010-10-20     Z   5.73   True  
  
In [577]: data.to_sql("data", engine)  
Out[577]: 3
```

With some databases, writing large DataFrames can result in errors due to packet size limitations being exceeded. This can be avoided by setting the `chunksize` parameter when calling `to_sql`. For example, the following writes data to the database in batches of 1000 rows at a time:

```
In [578]: data.to_sql("data_chunked", engine, chunksize=1000)
Out[578]: 3
```

SQL data types

`to_sql()` will try to map your data to an appropriate SQL data type based on the `dtype` of the data. When you have columns of `object` dtype, pandas will try to infer the data type.

You can always override the default type by specifying the desired SQL type of any of the columns by using the `dtype` argument. This argument needs a dictionary mapping column names to SQLAlchemy types (or strings for the sqlite3 fallback mode). For example, specifying to use the sqlalchemy `String` type instead of the default `Text` type for string columns:

```
In [579]: from sqlalchemy.types import String
In [580]: data.to_sql("data_dtype", engine, dtype={"Col_1": String})
Out[580]: 3
```

Note: Due to the limited support for `timedelta`'s in the different database flavors, columns with type `timedelta64` will be written as integer values as nanoseconds to the database and a warning will be raised.

Note: Columns of `category` dtype will be converted to the dense representation as you would get with `np.asarray(categorical)` (e.g. for string categories this gives an array of strings). Because of this, reading the database table back in does **not** generate a categorical.

Datetime data types

Using SQLAlchemy, `to_sql()` is capable of writing datetime data that is timezone naive or timezone aware. However, the resulting data stored in the database ultimately depends on the supported data type for datetime data of the database system being used.

The following table lists supported data types for datetime data for some common databases. Other database dialects may have different data types for datetime data.

Database	SQL Datetime Types	Timezone Support
SQLite	TEXT	No
MySQL	TIMESTAMP or DATETIME	No
PostgreSQL	TIMESTAMP or TIMESTAMP WITH TIME ZONE	Yes

When writing timezone aware data to databases that do not support timezones, the data will be written as timezone naive timestamps that are in local time with respect to the timezone.

`read_sql_table()` is also capable of reading datetime data that is timezone aware or naive. When reading `TIMESTAMP WITH TIME ZONE` types, pandas will convert the data to UTC.

Insertion method

The parameter `method` controls the SQL insertion clause used. Possible values are:

- `None`: Uses standard SQL `INSERT` clause (one per row).
- `'multi'`: Pass multiple values in a single `INSERT` clause. It uses a *special* SQL syntax not supported by all backends. This usually provides better performance for analytic databases like *Presto* and *Redshift*, but has worse performance for traditional SQL backend if the table contains many columns. For more information check the SQLAlchemy documentation.
- callable with signature (`pd_table, conn, keys, data_iter`): This can be used to implement a more performant insertion method based on specific backend dialect features.

Example of a callable using PostgreSQL `COPY` clause:

```
# Alternative to_sql() *method* for DBs that support COPY FROM
import csv
from io import StringIO

def psql_insert_copy(table, conn, keys, data_iter):
    """
    Execute SQL statement inserting data

    Parameters
    -----
    table : pandas.io.sql.SQLTable
    conn : sqlalchemy.engine.Engine or sqlalchemy.engine.Connection
    keys : list of str
        Column names
    data_iter : Iterable that iterates the values to be inserted
    """

    # gets a DBAPI connection that can provide a cursor
    dbapi_conn = conn.connection
    with dbapi_conn.cursor() as cur:
        s_buf = StringIO()
        writer = csv.writer(s_buf)
        writer.writerows(data_iter)
        s_buf.seek(0)

        columns = ', '.join(['"{}"'.format(k) for k in keys])
        if table.schema:
            table_name = '{}.{}'.format(table.schema, table.name)
        else:
            table_name = table.name

        sql = 'COPY {} ({}) FROM STDIN WITH CSV'.format(
            table_name, columns)
        cur.copy_expert(sql=sql, file=s_buf)
```

Reading tables

`read_sql_table()` will read a database table given the table name and optionally a subset of columns to read.

Note: In order to use `read_sql_table()`, you **must** have the SQLAlchemy optional dependency installed.

```
In [581]: pd.read_sql_table("data", engine)
```

Out[581]:

	index	id	Date	Col_1	Col_2	Col_3
0	0	26	2010-10-18	X	27.50	True
1	1	42	2010-10-19	Y	-12.50	False
2	2	63	2010-10-20	Z	5.73	True

Note: Note that pandas infers column dtypes from query outputs, and not by looking up data types in the physical database schema. For example, assume `userid` is an integer column in a table. Then, intuitively, `select userid ..` will return integer-valued series, while `select cast(userid as text) ..` will return object-valued (str) series. Accordingly, if the query output is empty, then all resulting columns will be returned as object-valued (since they are most general). If you foresee that your query will sometimes generate an empty result, you may want to explicitly typecast afterwards to ensure dtype integrity.

You can also specify the name of the column as the DataFrame index, and specify a subset of columns to be read.

```
In [582]: pd.read_sql_table("data", engine, index_col="id")
```

Out[582]:

	index	Date	Col_1	Col_2	Col_3
id					
26	0	2010-10-18	X	27.50	True
42	1	2010-10-19	Y	-12.50	False
63	2	2010-10-20	Z	5.73	True

```
In [583]: pd.read_sql_table("data", engine, columns=["Col_1", "Col_2"])
```

Out[583]:

	Col_1	Col_2
0	X	27.50
1	Y	-12.50
2	Z	5.73

And you can explicitly force columns to be parsed as dates:

```
In [584]: pd.read_sql_table("data", engine, parse_dates=["Date"])
```

Out[584]:

	index	id	Date	Col_1	Col_2	Col_3
0	0	26	2010-10-18	X	27.50	True
1	1	42	2010-10-19	Y	-12.50	False
2	2	63	2010-10-20	Z	5.73	True

If needed you can explicitly specify a format string, or a dict of arguments to pass to `pandas.to_datetime()`:

```
pd.read_sql_table("data", engine, parse_dates={"Date": "%Y-%m-%d"})
pd.read_sql_table(
    "data",
```

(continues on next page)

(continued from previous page)

```
    engine,
    parse_dates={"Date": {"format": "%Y-%m-%d %H:%M:%S"}},
)
```

You can check if a table exists using `has_table()`

Schema support

Reading from and writing to different schema's is supported through the `schema` keyword in the `read_sql_table()` and `to_sql()` functions. Note however that this depends on the database flavor (sqlite does not have schema's). For example:

```
df.to_sql("table", engine, schema="other_schema")
pd.read_sql_table("table", engine, schema="other_schema")
```

Querying

You can query using raw SQL in the `read_sql_query()` function. In this case you must use the SQL variant appropriate for your database. When using SQLAlchemy, you can also pass SQLAlchemy Expression language constructs, which are database-agnostic.

```
In [585]: pd.read_sql_query("SELECT * FROM data", engine)
Out[585]:
   index  id                  Date  Col_1  Col_2  Col_3
0      0  26  2010-10-18 00:00:00.000000    X  27.50      1
1      1  42  2010-10-19 00:00:00.000000    Y -12.50      0
2      2  63  2010-10-20 00:00:00.000000    Z   5.73      1
```

Of course, you can specify a more “complex” query.

```
In [586]: pd.read_sql_query("SELECT id, Col_1, Col_2 FROM data WHERE id = 42;", engine)
Out[586]:
   id  Col_1  Col_2
0   42     Y -12.5
```

The `read_sql_query()` function supports a `chunksize` argument. Specifying this will return an iterator through chunks of the query result:

```
In [587]: df = pd.DataFrame(np.random.randn(20, 3), columns=list("abc"))

In [588]: df.to_sql("data_chunks", engine, index=False)
Out[588]: 20
```

```
In [589]: for chunk in pd.read_sql_query("SELECT * FROM data_chunks", engine,
                                         chunksize=5):
    ....:     print(chunk)
    ....:
        a          b          c
0  0.092961 -0.674003  1.104153
1 -0.092732 -0.156246 -0.585167
```

(continues on next page)

(continued from previous page)

```

2 -0.358119 -0.862331 -1.672907
3 0.550313 -1.507513 -0.617232

4 -2.320335 -0.221090  0.119763

```

You can also run a plain query without creating a DataFrame with `execute()`. This is useful for queries that don't return values, such as `INSERT`. This is functionally equivalent to calling `execute` on the SQLAlchemy engine or db connection object. Again, you must use the SQL syntax variant appropriate for your database.

```

from pandas.io import sql

sql.execute("SELECT * FROM table_name", engine)
sql.execute(
    "INSERT INTO table_name VALUES(?, ?, ?)", engine, params=[("id", 1, 12.2, True)])
)

```

Engine connection examples

To connect with SQLAlchemy you use the `create_engine()` function to create an engine object from database URI. You only need to create the engine once per database you are connecting to.

```

from sqlalchemy import create_engine

engine = create_engine("postgresql://scott:tiger@localhost:5432/mydatabase")

engine = create_engine("mysql+mysqldb://scott:tiger@localhost/foo")

engine = create_engine("oracle://scott:tiger@127.0.0.1:1521/sidname")

engine = create_engine("mssql+pyodbc://mydsn")

# sqlite://<hostname>/<path>
# where <path> is relative:
engine = create_engine("sqlite:///foo.db")

```

(continues on next page)

(continued from previous page)

```
# or absolute, starting with a slash:
engine = create_engine("sqlite:///absolute/path/to/foo.db")
```

For more information see the examples the SQLAlchemy documentation

Advanced SQLAlchemy queries

You can use SQLAlchemy constructs to describe your query.

Use `sqlalchemy.text()` to specify query parameters in a backend-neutral way

```
In [590]: import sqlalchemy as sa

In [591]: pd.read_sql(
.....:     sa.text("SELECT * FROM data where Col_1=:col1"), engine, params={"col1": "X"
->""})
.....:
Out[591]:
   index  id          Date  Col_1  Col_2  Col_3
0      0  26  2010-10-18  00:00:00.000000      X    27.5      1
```

If you have an SQLAlchemy description of your database you can express where conditions using SQLAlchemy expressions

```
In [592]: metadata = sa.MetaData()

In [593]: data_table = sa.Table(
.....:     "data",
.....:     metadata,
.....:     sa.Column("index", sa.Integer),
.....:     sa.Column("Date", sa.DateTime),
.....:     sa.Column("Col_1", sa.String),
.....:     sa.Column("Col_2", sa.Float),
.....:     sa.Column("Col_3", sa.Boolean),
.....: )
.....:

In [594]: pd.read_sql(sa.select([data_table]).where(data_table.c.Col_3 is True), engine)
Out[594]:
Empty DataFrame
Columns: [index, Date, Col_1, Col_2, Col_3]
Index: []
```

You can combine SQLAlchemy expressions with parameters passed to `read_sql()` using `sqlalchemy.bindparam()`

```
In [595]: import datetime as dt

In [596]: expr = sa.select([data_table]).where(data_table.c.Date > sa.bindparam("date"))
```

(continues on next page)

(continued from previous page)

In [597]: `pd.read_sql(expr, engine, params={"date": dt.datetime(2010, 10, 18)})`

Out[597]:

	index	Date	Col_1	Col_2	Col_3
0	1	2010-10-19	Y	-12.50	False
1	2	2010-10-20	Z	5.73	True

Sqlite fallback

The use of sqlite is supported without using SQLAlchemy. This mode requires a Python database adapter which respect the Python DB-API.

You can create connections like so:

```
import sqlite3

con = sqlite3.connect(":memory:")
```

And then issue the following queries:

```
data.to_sql("data", con)
pd.read_sql_query("SELECT * FROM data", con)
```

2.4.17 Google BigQuery

Warning: Starting in 0.20.0, pandas has split off Google BigQuery support into the separate package `pandas-gbq`. You can `pip install pandas-gbq` to get it.

The `pandas-gbq` package provides functionality to read/write from Google BigQuery.

pandas integrates with this external package. if `pandas-gbq` is installed, you can use the pandas methods `pd.read_gbq` and `DataFrame.to_gbq`, which will call the respective functions from `pandas-gbq`.

Full documentation can be found [here](#).

2.4.18 Stata format

Writing to stata format

The method `to_stata()` will write a DataFrame into a .dta file. The format version of this file is always 115 (Stata 12).

In [598]: `df = pd.DataFrame(np.random.randn(10, 2), columns=list("AB"))`

In [599]: `df.to_stata("stata.dta")`

Stata data files have limited data type support; only strings with 244 or fewer characters, `int8`, `int16`, `int32`, `float32` and `float64` can be stored in .dta files. Additionally, *Stata* reserves certain values to represent missing data. Exporting a non-missing value that is outside of the permitted range in Stata for a particular data type will retype the variable to the next larger size. For example, `int8` values are restricted to lie between -127 and 100 in Stata, and so variables

with values above 100 will trigger a conversion to `int16`. `nan` values in floating points data types are stored as the basic missing data type (`.` in *Stata*).

Note: It is not possible to export missing data values for integer data types.

The *Stata* writer gracefully handles other data types including `int64`, `bool`, `uint8`, `uint16`, `uint32` by casting to the smallest supported type that can represent the data. For example, data with a type of `uint8` will be cast to `int8` if all values are less than 100 (the upper bound for non-missing `int8` data in *Stata*), or, if values are outside of this range, the variable is cast to `int16`.

Warning: Conversion from `int64` to `float64` may result in a loss of precision if `int64` values are larger than `2**53`.

Warning: `StataWriter` and `to_stata()` only support fixed width strings containing up to 244 characters, a limitation imposed by the version 115 dta file format. Attempting to write *Stata* dta files with strings longer than 244 characters raises a `ValueError`.

Reading from Stata format

The top-level function `read_stata` will read a dta file and return either a `DataFrame` or a `StataReader` that can be used to read the file incrementally.

```
In [600]: pd.read_stata("stata.dta")
Out[600]:
   index      A      B
0     0  0.608228  1.064810
1     1 -0.780506 -2.736887
2     2  0.143539  1.170191
3     3 -1.573076  0.075792
4     4 -1.722223 -0.774650
5     5  0.803627  0.221665
6     6  0.584637  0.147264
7     7  1.057825 -0.284136
8     8  0.912395  1.552808
9     9  0.189376 -0.109830
```

Specifying a `chunksize` yields a `StataReader` instance that can be used to read `chunksize` lines from the file at a time. The `StataReader` object can be used as an iterator.

```
In [601]: with pd.read_stata("stata.dta", chunksize=3) as reader:
.....:     for df in reader:
.....:         print(df.shape)
.....:
(3, 3)
(3, 3)
(3, 3)
(1, 3)
```

For more fine-grained control, use `iterator=True` and specify `chunksize` with each call to `read()`.

```
In [602]: with pd.read_stata("stata.dta", iterator=True) as reader:
.....:     chunk1 = reader.read(5)
.....:     chunk2 = reader.read(5)
.....:
```

Currently the `index` is retrieved as a column.

The parameter `convert_categoricals` indicates whether value labels should be read and used to create a `Categorical` variable from them. Value labels can also be retrieved by the function `value_labels`, which requires `read()` to be called before use.

The parameter `convert_missing` indicates whether missing value representations in Stata should be preserved. If `False` (the default), missing values are represented as `np.nan`. If `True`, missing values are represented using `StataMissingValue` objects, and columns containing missing values will have `object` data type.

Note: `read_stata()` and `StataReader` support .dta formats 113-115 (Stata 10-12), 117 (Stata 13), and 118 (Stata 14).

Note: Setting `preserve_dtypes=False` will upcast to the standard pandas data types: `int64` for all integer types and `float64` for floating point data. By default, the Stata data types are preserved when importing.

Categorical data

Categorical data can be exported to *Stata* data files as value labeled data. The exported data consists of the underlying category codes as integer data values and the categories as value labels. *Stata* does not have an explicit equivalent to a `Categorical` and information about *whether* the variable is ordered is lost when exporting.

Warning: *Stata* only supports string value labels, and so `str` is called on the categories when exporting data. Exporting `Categorical` variables with non-string categories produces a warning, and can result a loss of information if the `str` representations of the categories are not unique.

Labeled data can similarly be imported from *Stata* data files as `Categorical` variables using the keyword argument `convert_categoricals` (`True` by default). The keyword argument `order_categoricals` (`True` by default) determines whether imported `Categorical` variables are ordered.

Note: When importing categorical data, the values of the variables in the *Stata* data file are not preserved since `Categorical` variables always use integer data types between `-1` and `n-1` where `n` is the number of categories. If the original values in the *Stata* data file are required, these can be imported by setting `convert_categoricals=False`, which will import original data (but not the variable labels). The original values can be matched to the imported categorical data since there is a simple mapping between the original *Stata* data values and the category codes of imported `Categorical` variables: missing values are assigned code `-1`, and the smallest original value is assigned `0`, the second smallest is assigned `1` and so on until the largest original value is assigned the code `n-1`.

Note: *Stata* supports partially labeled series. These series have value labels for some but not all data values. Importing a partially labeled series will produce a `Categorical` with string categories for the values that are labeled and numeric categories for values with no label.

2.4.19 SAS formats

The top-level function `read_sas()` can read (but not write) SAS XPORT (.xpt) and (since v0.18.0) SAS7BDAT (.sas7bdat) format files.

SAS files only contain two value types: ASCII text and floating point values (usually 8 bytes but sometimes truncated). For xport files, there is no automatic type conversion to integers, dates, or categoricals. For SAS7BDAT files, the format codes may allow date variables to be automatically converted to dates. By default the whole file is read and returned as a `DataFrame`.

Specify a `chunksize` or use `iterator=True` to obtain reader objects (`XportReader` or `SAS7BDATReader`) for incrementally reading the file. The reader objects also have attributes that contain additional information about the file and its variables.

Read a SAS7BDAT file:

```
df = pd.read_sas("sas_data.sas7bdat")
```

Obtain an iterator and read an XPORT file 100,000 lines at a time:

```
def do_something(chunk):
    pass

with pd.read_sas("sas_xport.xpt", chunk=100000) as rdr:
    for chunk in rdr:
        do_something(chunk)
```

The specification for the xport file format is available from the SAS web site.

No official documentation is available for the SAS7BDAT format.

2.4.20 SPSS formats

New in version 0.25.0.

The top-level function `read_spss()` can read (but not write) SPSS SAV (.sav) and ZSAV (.zsav) format files.

SPSS files contain column names. By default the whole file is read, categorical columns are converted into `pd.Categorical`, and a `DataFrame` with all columns is returned.

Specify the `usecols` parameter to obtain a subset of columns. Specify `convert_categoricals=False` to avoid converting categorical columns into `pd.Categorical`.

Read an SPSS file:

```
df = pd.read_spss("spss_data.sav")
```

Extract a subset of columns contained in `usecols` from an SPSS file and avoid converting categorical columns into `pd.Categorical`:

```
df = pd.read_spss(
    "spss_data.sav",
    usecols=["foo", "bar"],
    convert_categoricals=False,
)
```

More information about the SAV and ZSAV file formats is available [here](#).

2.4.21 Other file formats

pandas itself only supports IO with a limited set of file formats that map cleanly to its tabular data model. For reading and writing other file formats into and from pandas, we recommend these packages from the broader community.

netCDF

`xarray` provides data structures inspired by the pandas `DataFrame` for working with multi-dimensional datasets, with a focus on the netCDF file format and easy conversion to and from pandas.

2.4.22 Performance considerations

This is an informal comparison of various IO methods, using pandas 0.24.2. Timings are machine dependent and small differences should be ignored.

```
In [1]: sz = 1000000
In [2]: df = pd.DataFrame({'A': np.random.randn(sz), 'B': [1] * sz})

In [3]: df.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 1000000 entries, 0 to 999999
Data columns (total 2 columns):
A    1000000 non-null float64
B    1000000 non-null int64
dtypes: float64(1), int64(1)
memory usage: 15.3 MB
```

The following test functions will be used below to compare the performance of several IO methods:

```
import numpy as np

import os

sz = 1000000
df = pd.DataFrame({'A': np.random.randn(sz), 'B': [1] * sz})

sz = 1000000
np.random.seed(42)
df = pd.DataFrame({'A': np.random.randn(sz), 'B': [1] * sz})

def test_sql_write(df):
    if os.path.exists("test.sql"):
        os.remove("test.sql")
    sql_db = sqlite3.connect("test.sql")
    df.to_sql(name="test_table", con=sql_db)
    sql_db.close()

def test_sql_read():
    sql_db = sqlite3.connect("test.sql")
    pd.read_sql_query("select * from test_table", sql_db)
```

(continues on next page)

(continued from previous page)

```
sql_db.close()

def test_hdf_fixed_write(df):
    df.to_hdf("test_fixed.hdf", "test", mode="w")

def test_hdf_fixed_read():
    pd.read_hdf("test_fixed.hdf", "test")

def test_hdf_fixed_write_compress(df):
    df.to_hdf("test_fixed_compress.hdf", "test", mode="w", complib="blosc")

def test_hdf_fixed_read_compress():
    pd.read_hdf("test_fixed_compress.hdf", "test")

def test_hdf_table_write(df):
    df.to_hdf("test_table.hdf", "test", mode="w", format="table")

def test_hdf_table_read():
    pd.read_hdf("test_table.hdf", "test")

def test_hdf_table_write_compress(df):
    df.to_hdf(
        "test_table_compress.hdf", "test", mode="w", complib="blosc", format="table"
    )

def test_hdf_table_read_compress():
    pd.read_hdf("test_table_compress.hdf", "test")

def test_csv_write(df):
    df.to_csv("test.csv", mode="w")

def test_csv_read():
    pd.read_csv("test.csv", index_col=0)

def test_feather_write(df):
    df.to_feather("test.feather")

def test_feather_read():
    pd.read_feather("test.feather")
```

(continues on next page)

(continued from previous page)

```

def test_pickle_write(df):
    df.to_pickle("test.pkl")

def test_pickle_read():
    pd.read_pickle("test.pkl")

def test_pickle_write_compress(df):
    df.to_pickle("test.pkl.compress", compression="xz")

def test_pickle_read_compress():
    pd.read_pickle("test.pkl.compress", compression="xz")

def test_parquet_write(df):
    df.to_parquet("test.parquet")

def test_parquet_read():
    pd.read_parquet("test.parquet")

```

When writing, the top three functions in terms of speed are `test_feather_write`, `test_hdf_fixed_write` and `test_hdf_fixed_write_compress`.

```

In [4]: %timeit test_sql_write(df)
3.29 s ± 43.2 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)

In [5]: %timeit test_hdf_fixed_write(df)
19.4 ms ± 560 µs per loop (mean ± std. dev. of 7 runs, 1 loop each)

In [6]: %timeit test_hdf_fixed_write_compress(df)
19.6 ms ± 308 µs per loop (mean ± std. dev. of 7 runs, 10 loops each)

In [7]: %timeit test_hdf_table_write(df)
449 ms ± 5.61 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)

In [8]: %timeit test_hdf_table_write_compress(df)
448 ms ± 11.9 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)

In [9]: %timeit test_csv_write(df)
3.66 s ± 26.2 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)

In [10]: %timeit test_feather_write(df)
9.75 ms ± 117 µs per loop (mean ± std. dev. of 7 runs, 100 loops each)

In [11]: %timeit test_pickle_write(df)

```

```
19.4 ms ± 436 µs per loop (mean ± std. dev. of 7 runs, 10 loops each)
```

```
In [16]: %timeit test_hdf_fixed_read_compress()
```

```
19.5 ms ± 222 µs per loop (mean ± std. dev. of 7 runs, 10 loops each)
```

```
In [17]: %timeit test_hdf_table_read()
```

```
38.6 ms ± 857 µs per loop (mean ± std. dev. of 7 runs, 10 loops each)
```

```
In [18]: %timeit test_hdf_table_read_compress()
```

```
38.8 ms ± 1.49 ms per loop (mean ± std. dev. of 7 runs, 10 loops each)
```

```
In [19]: %timeit test_csv_read()
```

```
452 ms ± 9.04 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)
```

```
In [20]: %timeit test_feather_read()
```

```
12.4 ms ± 99.7 µs per loop (mean ± std. dev. of 7 runs, 100 loops each)
```

```
In [21]: %timeit test_pickle_read()
```

```
18.4 ms ± 191 µs per loop (mean ± std. dev. of 7 runs, 100 loops each)
```

```
In [22]: %timeit test_pickle_read_compress()
```

```
915 ms ± 7.48 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)
```

```
In [23]: %timeit test_parquet_read()
```

```
24.4 ms ± 146 µs per loop (mean ± std. dev. of 7 runs, 10 loops each)
```

The files `test.pkl.compress`, `test.parquet` and `test.feather` took the least space on disk (in bytes).

```

24458940 Oct 10 06:44 test_table_compress.hdf
```

2.5 Indexing and selecting data

The axis labeling information in pandas objects serves many purposes:

- Identifies data (i.e. provides *metadata*) using known indicators, important for analysis, visualization, and interactive console display.
- Enables automatic and explicit data alignment.
- Allows intuitive getting and setting of subsets of the data set.

In this section, we will focus on the final point: namely, how to slice, dice, and generally get and set subsets of pandas objects. The primary focus will be on Series and DataFrame as they have received more development attention in this area.

Note: The Python and NumPy indexing operators [] and attribute operator . provide quick and easy access to pandas data structures across a wide range of use cases. This makes interactive work intuitive, as there's little new to learn if you already know how to deal with Python dictionaries and NumPy arrays. However, since the type of the data to be accessed isn't known in advance, directly using standard operators has some optimization limits. For production code, we recommended that you take advantage of the optimized pandas data access methods exposed in this chapter.

Warning: Whether a copy or a reference is returned for a setting operation, may depend on the context. This is sometimes called `chained assignment` and should be avoided. See [Returning a View versus Copy](#).

See the [MultiIndex / Advanced Indexing](#) for MultiIndex and more advanced indexing documentation.

See the [cookbook](#) for some advanced strategies.

2.5.1 Different choices for indexing

Object selection has had a number of user-requested additions in order to support more explicit location based indexing. pandas now supports three types of multi-axis indexing.

- `.loc` is primarily label based, but may also be used with a boolean array. `.loc` will raise `KeyError` when the items are not found. Allowed inputs are:
 - A single label, e.g. 5 or 'a' (Note that 5 is interpreted as a *label* of the index. This use is **not** an integer position along the index.).
 - A list or array of labels ['a', 'b', 'c'].
 - A slice object with labels 'a':'f' (Note that contrary to usual Python slices, **both** the start and the stop are included, when present in the index! See [Slicing with labels](#) and [Endpoints are inclusive](#).)
 - A boolean array (any NA values will be treated as `False`).
 - A callable function with one argument (the calling Series or DataFrame) and that returns valid output for indexing (one of the above).

See more at [Selection by Label](#).

- `.iloc` is primarily integer position based (from 0 to `length-1` of the axis), but may also be used with a boolean array. `.iloc` will raise `IndexError` if a requested indexer is out-of-bounds, except `slice` indexers which allow out-of-bounds indexing. (this conforms with Python/NumPy *slice* semantics). Allowed inputs are:
 - An integer e.g. 5.

- A list or array of integers [4, 3, 0].
- A slice object with ints 1:7.
- A boolean array (any NA values will be treated as False).
- A callable function with one argument (the calling Series or DataFrame) and that returns valid output for indexing (one of the above).

See more at [Selection by Position](#), [Advanced Indexing](#) and [Advanced Hierarchical](#).

- .loc, .iloc, and also [] indexing can accept a callable as indexer. See more at [Selection By Callable](#).

Getting values from an object with multi-axes selection uses the following notation (using .loc as an example, but the following applies to .iloc as well). Any of the axes accessors may be the null slice :. Axes left out of the specification are assumed to be :, e.g. p.loc['a'] is equivalent to p.loc['a', :, :].

Object Type	Indexers
Series	s.loc[indexer]
DataFrame	df.loc[row_indexer,column_indexer]

2.5.2 Basics

As mentioned when introducing the data structures in the [last section](#), the primary function of indexing with [] (a.k.a. __getitem__ for those familiar with implementing class behavior in Python) is selecting out lower-dimensional slices. The following table shows return type values when indexing pandas objects with []:

Object Type	Selection	Return Value Type
Series	series[label]	scalar value
DataFrame	frame[colname]	Series corresponding to colname

Here we construct a simple time series data set to use for illustrating the indexing functionality:

```
In [1]: dates = pd.date_range('1/1/2000', periods=8)
In [2]: df = pd.DataFrame(np.random.randn(8, 4),
   ...:                     index=dates, columns=['A', 'B', 'C', 'D'])
...
In [3]: df
Out[3]:
          A         B         C         D
2000-01-01  0.469112 -0.282863 -1.509059 -1.135632
2000-01-02  1.212112 -0.173215  0.119209 -1.044236
2000-01-03 -0.861849 -2.104569 -0.494929  1.071804
2000-01-04  0.721555 -0.706771 -1.039575  0.271860
2000-01-05 -0.424972  0.567020  0.276232 -1.087401
2000-01-06 -0.673690  0.113648 -1.478427  0.524988
2000-01-07  0.404705  0.577046 -1.715002 -1.039268
2000-01-08 -0.370647 -1.157892 -1.344312  0.844885
```

Note: None of the indexing functionality is time series specific unless specifically stated.

Thus, as per above, we have the most basic indexing using []:

```
In [4]: s = df['A']

In [5]: s[dates[5]]
Out[5]: -0.6736897080883706
```

You can pass a list of columns to [] to select columns in that order. If a column is not contained in the DataFrame, an exception will be raised. Multiple columns can also be set in this manner:

```
In [6]: df
Out[6]:
          A         B         C         D
2000-01-01  0.469112 -0.282863 -1.509059 -1.135632
2000-01-02  1.212112 -0.173215  0.119209 -1.044236
2000-01-03 -0.861849 -2.104569 -0.494929  1.071804
2000-01-04  0.721555 -0.706771 -1.039575  0.271860
2000-01-05 -0.424972  0.567020  0.276232 -1.087401
2000-01-06 -0.673690  0.113648 -1.478427  0.524988
2000-01-07  0.404705  0.577046 -1.715002 -1.039268
2000-01-08 -0.370647 -1.157892 -1.344312  0.844885
```

```
In [7]: df[['B', 'A']] = df[['A', 'B']]
```

```
In [8]: df
Out[8]:
          A         B         C         D
2000-01-01 -0.282863  0.469112 -1.509059 -1.135632
2000-01-02 -0.173215  1.212112  0.119209 -1.044236
2000-01-03 -2.104569 -0.861849 -0.494929  1.071804
2000-01-04 -0.706771  0.721555 -1.039575  0.271860
2000-01-05  0.567020 -0.424972  0.276232 -1.087401
2000-01-06  0.113648 -0.673690 -1.478427  0.524988
2000-01-07  0.577046  0.404705 -1.715002 -1.039268
2000-01-08 -1.157892 -0.370647 -1.344312  0.844885
```

You may find this useful for applying a transform (in-place) to a subset of the columns.

Warning: pandas aligns all AXES when setting Series and DataFrame from .loc, and .iloc.

This will **not** modify df because the column alignment is before value assignment.

```
In [9]: df[['A', 'B']]
Out[9]:
          A         B
2000-01-01 -0.282863  0.469112
2000-01-02 -0.173215  1.212112
2000-01-03 -2.104569 -0.861849
2000-01-04 -0.706771  0.721555
2000-01-05  0.567020 -0.424972
2000-01-06  0.113648 -0.673690
2000-01-07  0.577046  0.404705
2000-01-08 -1.157892 -0.370647
```

```
In [10]: df.loc[:, ['B', 'A']] = df[['A', 'B']]
```

```
In [11]: df[['A', 'B']]  
Out[11]:
```

	A	B
2000-01-01	-0.282863	0.469112
2000-01-02	-0.173215	1.212112
2000-01-03	-2.104569	-0.861849
2000-01-04	-0.706771	0.721555
2000-01-05	0.567020	-0.424972
2000-01-06	0.113648	-0.673690
2000-01-07	0.577046	0.404705
2000-01-08	-1.157892	-0.370647

The correct way to swap column values is by using raw values:

```
In [12]: df.loc[:, ['B', 'A']] = df[['A', 'B']].to_numpy()
```

```
In [13]: df[['A', 'B']]  
Out[13]:
```

	A	B
2000-01-01	0.469112	-0.282863
2000-01-02	1.212112	-0.173215
2000-01-03	-0.861849	-2.104569
2000-01-04	0.721555	-0.706771
2000-01-05	-0.424972	0.567020
2000-01-06	-0.673690	0.113648
2000-01-07	0.404705	0.577046
2000-01-08	-0.370647	-1.157892

2.5.3 Attribute access

You may access an index on a Series or column on a DataFrame directly as an attribute:

```
In [14]: sa = pd.Series([1, 2, 3], index=list('abc'))
```

```
In [15]: dfa = df.copy()
```

```
In [16]: sa.b  
Out[16]: 2  
  
In [17]: dfa.A  
Out[17]:
```

2000-01-01	0.469112
2000-01-02	1.212112
2000-01-03	-0.861849
2000-01-04	0.721555
2000-01-05	-0.424972
2000-01-06	-0.673690
2000-01-07	0.404705
2000-01-08	-0.370647

Freq: D, Name: A, dtype: float64

```
In [18]: sa.a = 5
```

```
In [19]: sa
```

```
Out[19]:
```

```
a    5
b    2
c    3
dtype: int64
```

```
In [20]: dfa.A = list(range(len(dfa.index))) # ok if A already exists
```

```
In [21]: dfa
```

```
Out[21]:
```

	A	B	C	D
2000-01-01	0	-0.282863	-1.509059	-1.135632
2000-01-02	1	-0.173215	0.119209	-1.044236
2000-01-03	2	-2.104569	-0.494929	1.071804
2000-01-04	3	-0.706771	-1.039575	0.271860
2000-01-05	4	0.567020	0.276232	-1.087401
2000-01-06	5	0.113648	-1.478427	0.524988
2000-01-07	6	0.577046	-1.715002	-1.039268
2000-01-08	7	-1.157892	-1.344312	0.844885

```
In [22]: dfa['A'] = list(range(len(dfa.index))) # use this form to create a new column
```

```
In [23]: dfa
```

```
Out[23]:
```

	A	B	C	D
2000-01-01	0	-0.282863	-1.509059	-1.135632
2000-01-02	1	-0.173215	0.119209	-1.044236
2000-01-03	2	-2.104569	-0.494929	1.071804
2000-01-04	3	-0.706771	-1.039575	0.271860
2000-01-05	4	0.567020	0.276232	-1.087401
2000-01-06	5	0.113648	-1.478427	0.524988
2000-01-07	6	0.577046	-1.715002	-1.039268
2000-01-08	7	-1.157892	-1.344312	0.844885

Warning:

- You can use this access only if the index element is a valid Python identifier, e.g. `s.1` is not allowed. See [here](#) for an explanation of valid identifiers.
- The attribute will not be available if it conflicts with an existing method name, e.g. `s.min` is not allowed, but `s['min']` is possible.
- Similarly, the attribute will not be available if it conflicts with any of the following list: `index`, `major_axis`, `minor_axis`, `items`.
- In any of these cases, standard indexing will still work, e.g. `s['1']`, `s['min']`, and `s['index']` will access the corresponding element or column.

If you are using the IPython environment, you may also use tab-completion to see these accessible attributes.

You can also assign a `dict` to a row of a `DataFrame`:

```
In [24]: x = pd.DataFrame({'x': [1, 2, 3], 'y': [3, 4, 5]})  
  
In [25]: x.iloc[1] = {'x': 9, 'y': 99}  
  
In [26]: x  
Out[26]:
```

	x	y
0	1	3
1	9	99
2	3	5

You can use attribute access to modify an existing element of a Series or column of a DataFrame, but be careful; if you try to use attribute access to create a new column, it creates a new attribute rather than a new column. In 0.21.0 and later, this will raise a UserWarning:

```
In [1]: df = pd.DataFrame({'one': [1., 2., 3.]})  
In [2]: df.two = [4, 5, 6]  
UserWarning: Pandas doesn't allow Series to be assigned into nonexistent columns - see https://pandas.pydata.org/pandas-docs/stable/indexing.html#attribute\_access  
In [3]: df  
Out[3]:
```

	one
0	1.0
1	2.0
2	3.0

2.5.4 Slicing ranges

The most robust and consistent way of slicing ranges along arbitrary axes is described in the [Selection by Position](#) section detailing the `.iloc` method. For now, we explain the semantics of slicing using the `[]` operator.

With Series, the syntax works exactly as with an ndarray, returning a slice of the values and the corresponding labels:

```
In [27]: s[:5]  
Out[27]:  
2000-01-01    0.469112  
2000-01-02    1.212112  
2000-01-03   -0.861849  
2000-01-04    0.721555  
2000-01-05   -0.424972  
Freq: D, Name: A, dtype: float64  
  
In [28]: s[::-2]  
Out[28]:  
2000-01-01    0.469112  
2000-01-03   -0.861849  
2000-01-05   -0.424972  
2000-01-07    0.404705  
Freq: 2D, Name: A, dtype: float64  
  
In [29]: s[::-1]  
Out[29]:
```

(continues on next page)

(continued from previous page)

```

2000-01-08 -0.370647
2000-01-07 0.404705
2000-01-06 -0.673690
2000-01-05 -0.424972
2000-01-04 0.721555
2000-01-03 -0.861849
2000-01-02 1.212112
2000-01-01 0.469112
Freq: -1D, Name: A, dtype: float64

```

Note that setting works as well:

```

In [30]: s2 = s.copy()

In [31]: s2[:5] = 0

In [32]: s2
Out[32]:
2000-01-01 0.000000
2000-01-02 0.000000
2000-01-03 0.000000
2000-01-04 0.000000
2000-01-05 0.000000
2000-01-06 -0.673690
2000-01-07 0.404705
2000-01-08 -0.370647
Freq: D, Name: A, dtype: float64

```

With DataFrame, slicing inside of [] **slices the rows**. This is provided largely as a convenience since it is such a common operation.

```

In [33]: df[:3]
Out[33]:
          A         B         C         D
2000-01-01 0.469112 -0.282863 -1.509059 -1.135632
2000-01-02 1.212112 -0.173215 0.119209 -1.044236
2000-01-03 -0.861849 -2.104569 -0.494929 1.071804

In [34]: df[::-1]
Out[34]:
          A         B         C         D
2000-01-08 -0.370647 -1.157892 -1.344312 0.844885
2000-01-07 0.404705 0.577046 -1.715002 -1.039268
2000-01-06 -0.673690 0.113648 -1.478427 0.524988
2000-01-05 -0.424972 0.567020 0.276232 -1.087401
2000-01-04 0.721555 -0.706771 -1.039575 0.271860
2000-01-03 -0.861849 -2.104569 -0.494929 1.071804
2000-01-02 1.212112 -0.173215 0.119209 -1.044236
2000-01-01 0.469112 -0.282863 -1.509059 -1.135632

```

2.5.5 Selection by label

Warning: Whether a copy or a reference is returned for a setting operation, may depend on the context. This is sometimes called `chained assignment` and should be avoided. See [Returning a View versus Copy](#).

Warning:

.loc is strict when you present slicers that are not compatible (or convertible) with the index type. For example using integers in a DatetimeIndex. These will raise a `TypeError`.

```
In [35]: df1 = pd.DataFrame(np.random.randn(5, 4),
....:                      columns=list('ABCD'),
....:                      index=pd.date_range('20130101', periods=5))
....:
```

```
In [36]: df1
Out[36]:
          A         B         C         D
2013-01-01  1.075770 -0.109050  1.643563 -1.469388
2013-01-02  0.357021 -0.674600 -1.776904 -0.968914
2013-01-03 -1.294524  0.413738  0.276662 -0.472035
2013-01-04 -0.013960 -0.362543 -0.006154 -0.923061
2013-01-05  0.895717  0.805244 -1.206412  2.565646
```

```
In [4]: df1.loc[2:3]
```

`TypeError: cannot do slice indexing on <class 'pandas.tseries.index.DatetimeIndex'>`
`~with these indexers [2] of <type 'int'>`

String likes in slicing *can* be convertible to the type of the index and lead to natural slicing.

```
In [37]: df1.loc['20130102':'20130104']
Out[37]:
          A         B         C         D
2013-01-02  0.357021 -0.674600 -1.776904 -0.968914
2013-01-03 -1.294524  0.413738  0.276662 -0.472035
2013-01-04 -0.013960 -0.362543 -0.006154 -0.923061
```

Warning: Changed in version 1.0.0.

pandas will raise a `KeyError` if indexing with a list with missing labels. See [list-like Using loc with missing keys in a list is Deprecated](#).

pandas provides a suite of methods in order to have **purely label based indexing**. This is a strict inclusion based protocol. Every label asked for must be in the index, or a `KeyError` will be raised. When slicing, both the start bound **AND** the stop bound are *included*, if present in the index. Integers are valid labels, but they refer to the label **and not the position**.

The .loc attribute is the primary access method. The following are valid inputs:

- A single label, e.g. 5 or 'a' (Note that 5 is interpreted as a *label* of the index. This use is **not** an integer position along the index.).

- A list or array of labels ['a', 'b', 'c'].
- A slice object with labels 'a':'f' (Note that contrary to usual Python slices, **both** the start and the stop are included, when present in the index! See *Slicing with labels*.
- A boolean array.
- A **callable**, see *Selection By Callable*.

```
In [38]: s1 = pd.Series(np.random.randn(6), index=list('abcdef'))
```

```
In [39]: s1
```

```
Out[39]:
```

```
a    1.431256
b    1.340309
c   -1.170299
d   -0.226169
e    0.410835
f    0.813850
dtype: float64
```

```
In [40]: s1.loc['c':]
```

```
Out[40]:
```

```
c   -1.170299
d   -0.226169
e    0.410835
f    0.813850
dtype: float64
```

```
In [41]: s1.loc['b']
```

```
Out[41]: 1.3403088497993827
```

Note that setting works as well:

```
In [42]: s1.loc['c'] = 0
```

```
In [43]: s1
```

```
Out[43]:
```

```
a    1.431256
b    1.340309
c    0.000000
d    0.000000
e    0.000000
f    0.000000
dtype: float64
```

With a DataFrame:

```
In [44]: df1 = pd.DataFrame(np.random.randn(6, 4),
....:                         index=list('abcdef'),
....:                         columns=list('ABCD'))
....:
```

```
In [45]: df1
```

```
Out[45]:
```

(continues on next page)

(continued from previous page)

	A	B	C	D
a	0.132003	-0.827317	-0.076467	-1.187678
b	1.130127	-1.436737	-1.413681	1.607920
c	1.024180	0.569605	0.875906	-2.211372
d	0.974466	-2.006747	-0.410001	-0.078638
e	0.545952	-1.219217	-1.226825	0.769804
f	-1.281247	-0.727707	-0.121306	-0.097883

In [46]: df1.loc[['a', 'b', 'd'], :]**Out[46]:**

	A	B	C	D
a	0.132003	-0.827317	-0.076467	-1.187678
b	1.130127	-1.436737	-1.413681	1.607920
d	0.974466	-2.006747	-0.410001	-0.078638

Accessing via label slices:

In [47]: df1.loc['d':, 'A':'C']**Out[47]:**

	A	B	C
d	0.974466	-2.006747	-0.410001
e	0.545952	-1.219217	-1.226825
f	-1.281247	-0.727707	-0.121306

For getting a cross section using a label (equivalent to df.xs('a')):

In [48]: df1.loc['a']**Out[48]:**

A	0.132003
B	-0.827317
C	-0.076467
D	-1.187678
Name: a, dtype: float64	

For getting values with a boolean array:

In [49]: df1.loc['a'] > 0**Out[49]:**

A	True
B	False
C	False
D	False
Name: a, dtype: bool	

In [50]: df1.loc[:, df1.loc['a'] > 0]**Out[50]:**

	A
a	0.132003
b	1.130127
c	1.024180
d	0.974466
e	0.545952
f	-1.281247

NA values in a boolean array propagate as False:

Changed in version 1.0.2.

```
In [51]: mask = pd.array([True, False, True, False, pd.NA, False], dtype="boolean")

In [52]: mask
Out[52]:
<BooleanArray>
[True, False, True, False, <NA>, False]
Length: 6, dtype: boolean

In [53]: df1[mask]
Out[53]:
      A          B          C          D
a  0.132003 -0.827317 -0.076467 -1.187678
c  1.024180  0.569605  0.875906 -2.211372
```

For getting a value explicitly:

```
# this is also equivalent to ``df1.at['a', 'A']``
In [54]: df1.loc['a', 'A']
Out[54]: 0.13200317033032932
```

Slicing with labels

When using .loc with slices, if both the start and the stop labels are present in the index, then elements *located* between the two (including them) are returned:

```
In [55]: s = pd.Series(list('abcde'), index=[0, 3, 2, 5, 4])

In [56]: s.loc[3:5]
Out[56]:
3    b
2    c
5    d
dtype: object
```

If at least one of the two is absent, but the index is sorted, and can be compared against start and stop labels, then slicing will still work as expected, by selecting labels which *rank* between the two:

```
In [57]: s.sort_index()
Out[57]:
0    a
2    c
3    b
4    e
5    d
dtype: object

In [58]: s.sort_index().loc[1:6]
Out[58]:
2    c
```

(continues on next page)

(continued from previous page)

```
3    b
4    e
5    d
dtype: object
```

However, if at least one of the two is absent *and* the index is not sorted, an error will be raised (since doing otherwise would be computationally expensive, as well as potentially ambiguous for mixed type indexes). For instance, in the above example, `s.loc[1:6]` would raise `KeyError`.

For the rationale behind this behavior, see [Endpoints are inclusive](#).

```
In [59]: s = pd.Series(list('abcdef'), index=[0, 3, 2, 5, 4, 2])
```

```
In [60]: s.loc[3:5]
```

```
Out[60]:
```

```
3    b
2    c
5    d
dtype: object
```

Also, if the index has duplicate labels *and* either the start or the stop label is duplicated, an error will be raised. For instance, in the above example, `s.loc[2:5]` would raise a `KeyError`.

For more information about duplicate labels, see [Duplicate Labels](#).

2.5.6 Selection by position

Warning: Whether a copy or a reference is returned for a setting operation, may depend on the context. This is sometimes called [chained assignment](#) and should be avoided. See [Returning a View versus Copy](#).

pandas provides a suite of methods in order to get **purely integer based indexing**. The semantics follow closely Python and NumPy slicing. These are **0-based indexing**. When slicing, the start bound is *included*, while the upper bound is *excluded*. Trying to use a non-integer, even a **valid** label will raise an `IndexError`.

The `.iloc` attribute is the primary access method. The following are valid inputs:

- An integer e.g. 5.
- A list or array of integers [4, 3, 0].
- A slice object with ints 1:7.
- A boolean array.
- A `callable`, see [Selection By Callable](#).

```
In [61]: s1 = pd.Series(np.random.randn(5), index=list(range(0, 10, 2)))
```

```
In [62]: s1
```

```
Out[62]:
```

```
0    0.695775
2    0.341734
4    0.959726
6   -1.110336
```

(continues on next page)

(continued from previous page)

```
8    -0.619976
dtype: float64
```

In [63]: s1.iloc[:3]

Out[63]:

```
0    0.695775
2    0.341734
4    0.959726
dtype: float64
```

In [64]: s1.iloc[3]

Out[64]: -1.110336102891167

Note that setting works as well:

In [65]: s1.iloc[:3] = 0

In [66]: s1

Out[66]:

```
0    0.000000
2    0.000000
4    0.000000
6   -1.110336

Out[88]:

	A	B
4	0.27423	0.132885

A single indexer that is out of bounds will raise an `IndexError`. A list of indexers where any element is out of bounds will raise an `IndexError`.

```
>>> df1.iloc[[4, 5, 6]]
IndexError: positional indexers are out-of-bounds
```

```
>>> df1.iloc[:, 4]
IndexError: single positional indexer is out-of-bounds
```

2.5.7 Selection by callable

`.loc`, `.iloc`, and also `[]` indexing can accept a `callable` as indexer. The callable must be a function with one argument (the calling Series or DataFrame) that returns valid output for indexing.

```
In [89]: df1 = pd.DataFrame(np.random.randn(6, 4),
.....:                               index=list('abcdef'),
.....:                               columns=list('ABCD'))
.....:
```

In [90]: df1

Out[90]:

	A	B	C	D
a	-0.023688	2.410179	1.450520	0.206053
b	-0.251905	-2.213588	1.063327	1.266143
c	0.299368	-0.863838	0.408204	-1.048089
d	-0.025747	-0.988387	0.094055	1.262731
e	1.289997	0.082423	-0.055758	0.536580
f	-0.489682	0.369374	-0.034571	-2.484478

In [91]: df1.loc[lambda df: df['A'] > 0, :]

Out[91]:

	A	B	C	D
c	0.299368	-0.863838	0.408204	-1.048089
e	1.289997	0.082423	-0.055758	0.536580

In [92]: df1.loc[:, lambda df: ['A', 'B']]

Out[92]:

	A	B
a	-0.023688	2.410179
b	-0.251905	-2.213588
c	0.299368	-0.863838

(continues on next page)

(continued from previous page)

```
d -0.025747 -0.988387
e 1.289997 0.082423
f -0.489682 0.369374
```

In [93]: df1.iloc[:, lambda df: [0, 1]]

Out[93]:

	A	B
a	-0.023688	2.410179
b	-0.251905	-2.213588
c	0.299368	-0.863838
d	-0.025747	-0.988387
e	1.289997	0.082423
f	-0.489682	0.369374

In [94]: df1[lambda df: df.columns[0]]

Out[94]:

	A
a	-0.023688
b	-0.251905
c	0.299368
d	-0.025747
e	1.289997
f	-0.489682

Name: A, dtype: float64

You can use callable indexing in Series.

In [95]: df1['A'].loc[lambda s: s > 0]

Out[95]:

	A
c	0.299368
e	1.289997

Name: A, dtype: float64

Using these methods / indexers, you can chain data selection operations without using a temporary variable.

In [96]: bb = pd.read_csv('data/baseball.csv', index_col='id')

In [97]: (bb.groupby(['year', 'team']).sum()
..... .loc[lambda df: df['r'] > 100])
.....

Out[97]:

year	team	stint	g	ab	r	h	X2b	X3b	hr	rbi	sb	cs	bb	so	ibb
		hbp	sh	sf	gidp										
2007	CIN	6	379	745	101	203	35	2	36	125.0	10.0	1.0	105	127.0	14.0

	DET	5	301	1062	162	283	54	4	37	144.0	24.0	7.0	97	176.0	3.0
		10.0	4.0	8.0	28.0										
	HOU	4	311	926	109	218	47	6	14	77.0	10.0	4.0	60	212.0	3.0
		9.0	16.0	6.0	17.0										
	LAN	11	413	1021	153	293	61	3	36	154.0	7.0	5.0	114	141.0	8.0
		9.0	3.0	8.0	29.0										

(continues on next page)

(continued from previous page)

2.5.8 Combining positional and label-based indexing

If you wish to get the 0th and the 2nd elements from the index in the 'A' column, you can do:

```
In [98]: dfd = pd.DataFrame({'A': [1, 2, 3],  
.....: 'B': [4, 5, 6]},  
.....: index=list('abc'))  
.....:  
  
In [99]: dfd  
Out[99]:  
A   B  
a   1   4  
b   2   5  
c   3   6  
  
In [100]: dfd.loc[dfd.index[[0, 2]], 'A']  
Out[100]:  
a    1  
c    3  
Name: A, dtype: int64
```

This can also be expressed using `.iloc`, by explicitly getting locations on the indexers, and using *positional* indexing to select things.

```
In [101]: dfd.iloc[[0, 2], dfd.columns.get_loc('A')]  
Out[101]:  
a    1  
c    3  
Name: A, dtype: int64
```

For getting *multiple* indexers, using .get_indexer:

```
In [102]: dfd.iloc[[0, 2], dfd.columns.get_indexer(['A', 'B'])]
Out[102]:
   A   B
a  1   4
c  3   6
```

2.5.9 Indexing with list with missing labels is deprecated

Warning: Changed in version 1.0.0.

Using .loc or [] with a list with one or more missing labels will no longer reindex, in favor of .reindex.

In prior versions, using .loc[list-of-labels] would work as long as *at least 1* of the keys was found (otherwise it would raise a `KeyError`). This behavior was changed and will now raise a `KeyError` if at least one label is missing. The recommended alternative is to use `.reindex()`.

For example.

```
In [103]: s = pd.Series([1, 2, 3])
In [104]: s
Out[104]:
0    1
1    2
2    3
dtype: int64
```

Selection with all keys found is unchanged.

```
In [105]: s.loc[[1, 2]]
Out[105]:
1    2
2    3
dtype: int64
```

Previous behavior

```
In [4]: s.loc[[1, 2, 3]]
Out[4]:
1    2.0
2    3.0
3    NaN
dtype: float64
```

Current behavior

```
In [4]: s.loc[[1, 2, 3]]
Passing list-like to .loc with any non-matching elements will raise
KeyError in the future, you can use .reindex() as an alternative.

See the documentation here:
https://pandas.pydata.org/pandas-docs/stable/indexing.html#deprecate-loc-reindex-listlike

Out[4]:
1    2.0
2    3.0
3    NaN
dtype: float64
```

Reindexing

The idiomatic way to achieve selecting potentially not-found elements is via `.reindex()`. See also the section on [reindexing](#).

```
In [106]: s.reindex([1, 2, 3])
```

```
Out[106]:
```

```
1    2.0
2    3.0
3    NaN
dtype: float64
```

Alternatively, if you want to select only *valid* keys, the following is idiomatic and efficient; it is guaranteed to preserve the dtype of the selection.

```
In [107]: labels = [1, 2, 3]
```

```
In [108]: s.loc[s.index.intersection(labels)]
```

```
Out[108]:
```

```
1    2
2    3
dtype: int64
```

Having a duplicated index will raise for a `.reindex()`:

```
In [109]: s = pd.Series(np.arange(4), index=['a', 'a', 'b', 'c'])
```

```
In [110]: labels = ['c', 'd']
```

```
In [17]: s.reindex(labels)
```

```
ValueError: cannot reindex on an axis with duplicate labels
```

Generally, you can intersect the desired labels with the current axis, and then reindex.

```
In [111]: s.loc[s.index.intersection(labels)].reindex(labels)
```

```
Out[111]:
```

```
c    3.0
d    NaN
dtype: float64
```

However, this would *still* raise if your resulting index is duplicated.

```
In [41]: labels = ['a', 'd']
```

```
In [42]: s.loc[s.index.intersection(labels)].reindex(labels)
```

```
ValueError: cannot reindex on an axis with duplicate labels
```

2.5.10 Selecting random samples

A random selection of rows or columns from a Series or DataFrame with the `sample()` method. The method will sample rows by default, and accepts a specific number of rows/columns to return, or a fraction of rows.

```
In [112]: s = pd.Series([0, 1, 2, 3, 4, 5])

# When no arguments are passed, returns 1 row.
In [113]: s.sample()
Out[113]:
4    4
dtype: int64

# One may specify either a number of rows:
In [114]: s.sample(n=3)
Out[114]:
0    0
4    4
1    1
dtype: int64

# Or a fraction of the rows:
In [115]: s.sample(frac=0.5)
Out[115]:
5    5
3    3
1    1
dtype: int64
```

By default, `sample` will return each row at most once, but one can also sample with replacement using the `replace` option:

```
In [116]: s = pd.Series([0, 1, 2, 3, 4, 5])

# Without replacement (default):
In [117]: s.sample(n=6, replace=False)
Out[117]:
0    0
1    1
5    5
3    3
2    2
4    4
dtype: int64

# With replacement:
In [118]: s.sample(n=6, replace=True)
Out[118]:
0    0
4    4
3    3
2    2
4    4
4    4
```

(continues on next page)

(continued from previous page)

```
dtype: int64
```

By default, each row has an equal probability of being selected, but if you want rows to have different probabilities, you can pass the `sample` function sampling weights as `weights`. These weights can be a list, a NumPy array, or a Series, but they must be of the same length as the object you are sampling. Missing values will be treated as a weight of zero, and inf values are not allowed. If weights do not sum to 1, they will be re-normalized by dividing all weights by the sum of the weights. For example:

```
In [119]: s = pd.Series([0, 1, 2, 3, 4, 5])

In [120]: example_weights = [0, 0, 0.2, 0.2, 0.2, 0.4]

In [121]: s.sample(n=3, weights=example_weights)
Out[121]:
5      5
4      4
3      3
dtype: int64

# Weights will be re-normalized automatically
In [122]: example_weights2 = [0.5, 0, 0, 0, 0, 0]

In [123]: s.sample(n=1, weights=example_weights2)
Out[123]:
0      0
dtype: int64
```

When applied to a DataFrame, you can use a column of the DataFrame as sampling weights (provided you are sampling rows and not columns) by simply passing the name of the column as a string.

```
In [124]: df2 = pd.DataFrame({'col1': [9, 8, 7, 6],
.....:                      'weight_column': [0.5, 0.4, 0.1, 0]})

In [125]: df2.sample(n=3, weights='weight_column')
Out[125]:
   col1  weight_column
1     8          0.4
0     9          0.5
2     7          0.1
```

`sample` also allows users to sample columns instead of rows using the `axis` argument.

```
In [126]: df3 = pd.DataFrame({'col1': [1, 2, 3], 'col2': [2, 3, 4]})

In [127]: df3.sample(n=1, axis=1)
Out[127]:
   col1
0     1
1     2
2     3
```

Finally, one can also set a seed for `sample`'s random number generator using the `random_state` argument, which will

accept either an integer (as a seed) or a NumPy RandomState object.

```
In [128]: df4 = pd.DataFrame({'col1': [1, 2, 3], 'col2': [2, 3, 4]})

# With a given seed, the sample will always draw the same rows.
In [129]: df4.sample(n=2, random_state=2)
Out[129]:
   col1  col2
2      3      4
1      2      3

In [130]: df4.sample(n=2, random_state=2)
Out[130]:
   col1  col2
2      3      4
1      2      3
```

2.5.11 Setting with enlargement

The `.loc/[]` operations can perform enlargement when setting a non-existent key for that axis.

In the Series case this is effectively an appending operation.

```
In [131]: se = pd.Series([1, 2, 3])

In [132]: se
Out[132]:
0    1
1    2
2    3
dtype: int64

In [133]: se[5] = 5.

In [134]: se
Out[134]:
0    1.0
1    2.0
2    3.0
5    5.0
dtype: float64
```

A DataFrame can be enlarged on either axis via `.loc`.

```
In [135]: dfi = pd.DataFrame(np.arange(6).reshape(3, 2),
                           columns=['A', 'B'])
.....
.....
In [136]: dfi
Out[136]:
   A  B
0  0  1
1  2  3
```

(continues on next page)

(continued from previous page)

```
2 4 5

In [137]: dfi.loc[:, 'C'] = dfi.loc[:, 'A']

In [138]: dfi
Out[138]:
   A   B   C
0  0   1   0
1  2   3   2
2  4   5   4
```

This is like an append operation on the DataFrame.

```
In [139]: dfi.loc[3] = 5

In [140]: dfi
Out[140]:
   A   B   C
0  0   1   0
1  2   3   2
2  4   5   4
3  5   5   5
```

2.5.12 Fast scalar value getting and setting

Since indexing with [] must handle a lot of cases (single-label access, slicing, boolean indexing, etc.), it has a bit of overhead in order to figure out what you're asking for. If you only want to access a scalar value, the fastest way is to use the `at` and `iat` methods, which are implemented on all of the data structures.

Similarly to `loc`, `at` provides `label` based scalar lookups, while, `iat` provides `integer` based lookups analogously to `iloc`

```
In [141]: s.iat[5]
Out[141]: 5

In [142]: df.at[dates[5], 'A']
Out[142]: -0.6736897080883706

In [143]: df.iat[3, 0]
Out[143]: 0.7215551622443669
```

You can also set using these same indexers.

```
In [144]: df.at[dates[5], 'E'] = 7
In [145]: df.iat[3, 0] = 7
```

`at` may enlarge the object in-place as above if the indexer is missing.

```
In [146]: df.at[dates[-1] + pd.Timedelta('1 day'), 0] = 7
In [147]: df
```

(continues on next page)

(continued from previous page)

Out[147]:

	A	B	C	D	E	0

2.5.13 Boolean indexing

Another common operation is the use of boolean vectors to filter the data. The operators are: `|` for `or`, `&` for `and`, and `~` for `not`. These **must** be grouped by using parentheses, since by default Python will evaluate an expression such as `df['A'] > 2 & df['B'] < 3` as `df['A'] > (2 & df['B']) < 3`, while the desired evaluation order is `(df['A'] > 2) & (df['B'] < 3)`.

Using a boolean vector to index a Series works exactly as in a NumPy ndarray:

In [148]: `s = pd.Series(range(-3, 4))`**In [149]:** `s`**Out[149]:**

```
0    -3
1    -2
2    -1
3     0
4     1
5     2
6     3
dtype: int64
```

In [150]: `s[s > 0]`**Out[150]:**

```
4     1
5     2
6     3
dtype: int64
```

In [151]: `s[(s < -1) | (s > 0.5)]`**Out[151]:**

```
0    -3
1    -2
4     1
5     2
6     3
dtype: int64
```

In [152]: `s[~(s < 0)]`

(continues on next page)

(continued from previous page)

Out[152]:

```
3    0
4    1
5    2
6    3
dtype: int64
```

You may select rows from a DataFrame using a boolean vector the same length as the DataFrame's index (for example, something derived from one of the columns of the DataFrame):

In [153]: df[df['A'] > 0]**Out[153]:**

	A	B	C	D	E	0
2000-01-01	0.469112	-0.282863	-1.509059	-1.135632	NaN	NaN
2000-01-02	1.212112	-0.173215	0.119209	-1.044236	NaN	NaN
2000-01-04	7.000000	-0.706771	-1.039575	0.271860	NaN	NaN
2000-01-07	0.404705	0.577046	-1.715002	-1.039268	NaN	NaN

List comprehensions and the `map` method of Series can also be used to produce more complex criteria:

```
In [154]: df2 = pd.DataFrame({'a': ['one', 'one', 'two', 'three', 'two', 'one', 'six'],
.....:                               'b': ['x', 'y', 'y', 'x', 'y', 'x', 'x'],
.....:                               'c': np.random.randn(7)})

# only want 'two' or 'three'
In [155]: criterion = df2['a'].map(lambda x: x.startswith('t'))

In [156]: df2[criterion]
Out[156]:
      a   b       c
2  two  y  0.041290
3 three  x  0.361719
4  two  y -0.238075

# equivalent but slower
In [157]: df2[[x.startswith('t') for x in df2['a']]]
Out[157]:
      a   b       c
2  two  y  0.041290
3 three  x  0.361719
4  two  y -0.238075

# Multiple criteria
In [158]: df2[criterion & (df2['b'] == 'x')]
Out[158]:
      a   b       c
3 three  x  0.361719
```

With the choice methods *Selection by Label*, *Selection by Position*, and *Advanced Indexing* you may select along more than one axis using boolean vectors combined with other indexing expressions.

```
In [159]: df2.loc[criterion & (df2['b'] == 'x'), 'b':'c']
Out[159]:
   b          c
3  x  0.361719
```

Warning: iloc supports two kinds of boolean indexing. If the indexer is a boolean Series, an error will be raised. For instance, in the following example, df.iloc[s.values, 1] is ok. The boolean indexer is an array. But df.iloc[s, 1] would raise ValueError.

```
In [160]: df = pd.DataFrame([[1, 2], [3, 4], [5, 6]],
.....:                 index=list('abc'),
.....:                 columns=['A', 'B'])
.....:

In [161]: s = (df['A'] > 2)

In [162]: s
Out[162]:
a    False
b    True
c    True
Name: A, dtype: bool

In [163]: df.loc[s, 'B']
Out[163]:
b    4
c    6
Name: B, dtype: int64

In [164]: df.iloc[s.values, 1]
Out[164]:
b    4
c    6
Name: B, dtype: int64
```

2.5.14 Indexing with isin

Consider the `isin()` method of Series, which returns a boolean vector that is true wherever the Series elements exist in the passed list. This allows you to select rows where one or more columns have values you want:

```
In [165]: s = pd.Series(np.arange(5), index=np.arange(5)[::-1], dtype='int64')

In [166]: s
Out[166]:
4    0
3    1
2    2
1    3
0    4
dtype: int64
```

(continues on next page)

(continued from previous page)

In [167]: s.isin([2, 4, 6])**Out[167]:**

```
4    False
3    False
2    True
1    False
0    True
dtype: bool
```

In [168]: s[s.isin([2, 4, 6])]**Out[168]:**

```
2    2
0    4
dtype: int64
```

The same method is available for Index objects and is useful for the cases when you don't know which of the sought labels are in fact present:

In [169]: s[s.index.isin([2, 4, 6])]**Out[169]:**

```
4    0
2    2
dtype: int64
```

compare it to the following

In [170]: s.reindex([2, 4, 6])**Out[170]:**

```
2    2.0
4    0.0
6    NaN
dtype: float64
```

In addition to that, MultiIndex allows selecting a separate level to use in the membership check:

In [171]: s_mi = pd.Series(np.arange(6),
.....: index=pd.MultiIndex.from_product([[0, 1], ['a', 'b', 'c']])))
.....:**In [172]:** s_mi**Out[172]:**

0	a	0
	b	1
	c	2
1	a	3
	b	4
	c	5

dtype: int64

In [173]: s_mi.iloc[s_mi.index.isin([(1, 'a'), (2, 'b'), (0, 'c'))])]**Out[173]:**

0	c	2
---	---	---

(continues on next page)

(continued from previous page)

```
1 a    3
dtype: int64

In [174]: s_mi.iloc[s_mi.index.isin(['a', 'c', 'e'], level=1)]
Out[174]:
0 a    0
c   2
1 a    3
c   5
dtype: int64
```

DataFrame also has an `isin()` method. When calling `isin`, pass a set of values as either an array or dict. If values is an array, `isin` returns a DataFrame of booleans that is the same shape as the original DataFrame, with True wherever the element is in the sequence of values.

```
In [175]: df = pd.DataFrame({'vals': [1, 2, 3, 4], 'ids': ['a', 'b', 'f', 'n'],
.....:           'ids2': ['a', 'n', 'c', 'n']})
.....:

In [176]: values = ['a', 'b', 1, 3]

In [177]: df.isin(values)
Out[177]:
   vals     ids   ids2
0  True    True   True
1 False   True  False
2  True  False  False
3 False  False  False
```

Oftentimes you'll want to match certain values with certain columns. Just make values a dict where the key is the column, and the value is a list of items you want to check for.

```
In [178]: values = {'ids': ['a', 'b'], 'vals': [1, 3]}

In [179]: df.isin(values)
Out[179]:
   vals     ids   ids2
0  True    True  False
1 False   True  False
2  True  False  False
3 False  False  False
```

To return the DataFrame of booleans where the values are *not* in the original DataFrame, use the `~` operator:

```
In [180]: values = {'ids': ['a', 'b'], 'vals': [1, 3]}

In [181]: ~df.isin(values)
Out[181]:
   vals     ids   ids2
0 False  False   True
1  True  False   True
2 False   True   True
3  True   True   True
```

Combine DataFrame's `isin` with the `any()` and `all()` methods to quickly select subsets of your data that meet a given criteria. To select a row where each column meets its own criterion:

```
In [182]: values = {'ids': ['a', 'b'], 'ids2': ['a', 'c'], 'vals': [1, 3]}

In [183]: row_mask = df.isin(values).all(1)

In [184]: df[row_mask]
Out[184]:
   vals  ids  ids2
0      1    a     a
```

2.5.15 The `where()` Method and Masking

Selecting values from a Series with a boolean vector generally returns a subset of the data. To guarantee that selection output has the same shape as the original data, you can use the `where` method in Series and DataFrame.

To return only the selected rows:

```
In [185]: s[s > 0]
Out[185]:
3    1
2    2
1    3
0    4
dtype: int64
```

To return a Series of the same shape as the original:

```
In [186]: s.where(s > 0)
Out[186]:
4    NaN
3    1.0
2    2.0
1    3.0
0    4.0
dtype: float64
```

Selecting values from a DataFrame with a boolean criterion now also preserves input data shape. `where` is used under the hood as the implementation. The code below is equivalent to `df.where(df < 0)`.

```
In [187]: df[df < 0]
Out[187]:
          A         B         C         D
2000-01-01 -2.104139 -1.309525      NaN      NaN
2000-01-02 -0.352480      NaN -1.192319      NaN
2000-01-03 -0.864883      NaN -0.227870      NaN
2000-01-04      NaN -1.222082      NaN -1.233203
2000-01-05      NaN -0.605656 -1.169184      NaN
2000-01-06      NaN -0.948458      NaN -0.684718
2000-01-07 -2.670153 -0.114722      NaN -0.048048
2000-01-08      NaN      NaN -0.048788 -0.808838
```

In addition, `where` takes an optional `other` argument for replacement of values where the condition is False, in the returned copy.

```
In [188]: df.where(df < 0, -df)
Out[188]:
          A         B         C         D
2000-01-01 -2.104139 -1.309525 -0.485855 -0.245166
2000-01-02 -0.352480 -0.390389 -1.192319 -1.655824
2000-01-03 -0.864883 -0.299674 -0.227870 -0.281059
2000-01-04 -0.846958 -1.222082 -0.600705 -1.233203
2000-01-05 -0.669692 -0.605656 -1.169184 -0.342416
2000-01-06 -0.868584 -0.948458 -2.297780 -0.684718
2000-01-07 -2.670153 -0.114722 -0.168904 -0.048048
2000-01-08 -0.801196 -1.392071 -0.048788 -0.808838
```

You may wish to set values based on some boolean criteria. This can be done intuitively like so:

```
In [189]: s2 = s.copy()
In [190]: s2[s2 < 0] = 0
In [191]: s2
Out[191]:
4      0
3      1
2      2
1      3
0      4
dtype: int64

In [192]: df2 = df.copy()
In [193]: df2[df2 < 0] = 0
In [194]: df2
Out[194]:
          A         B         C         D
2000-01-01 0.000000 0.000000 0.485855 0.245166
2000-01-02 0.000000 0.390389 0.000000 1.655824
2000-01-03 0.000000 0.299674 0.000000 0.281059
2000-01-04 0.846958 0.000000 0.600705 0.000000
2000-01-05 0.669692 0.000000 0.000000 0.342416
2000-01-06 0.868584 0.000000 2.297780 0.000000
2000-01-07 0.000000 0.000000 0.168904 0.000000
2000-01-08 0.801196 1.392071 0.000000 0.000000
```

By default, `where` returns a modified copy of the data. There is an optional parameter `inplace` so that the original data can be modified without creating a copy:

```
In [195]: df_orig = df.copy()
In [196]: df_orig.where(df > 0, -df, inplace=True)
In [197]: df_orig
```

(continues on next page)

(continued from previous page)

Out[197]:

	A	B	C	D
2000-01-01	2.104139	1.309525	0.485855	0.245166
2000-01-02	0.352480	0.390389	1.192319	1.655824

2000-01-07	True	True	True	True
2000-01-08	True	True	True	True

Alignment

Furthermore, `where` aligns the input boolean condition (ndarray or DataFrame), such that partial selection with setting is possible. This is analogous to partial setting via `.loc` (but on the contents rather than the axis labels).

In [199]: `df2 = df.copy()`**In [200]:** `df2[df2[1:4] > 0] = 3`**In [201]:** `df2`**Out[201]:**

	A	B	C	D
2000-01-01	-2.104139	-1.309525	0.485855	0.245166
2000-01-02	-0.352480	3.000000	-1.192319	3.000000
2000-01-03	-0.864883	3.000000	-0.227870	3.000000
2000-01-04	3.000000	-1.222082	3.000000	-1.233203
2000-01-05	0.669692	-0.605656	-1.169184	0.342416
2000-01-06	0.868584	-0.948458	2.297780	-0.684718
2000-01-07	-2.670153	-0.114722	0.168904	-0.048048
2000-01-08	0.801196	1.392071	-0.048788	-0.808838

Where can also accept `axis` and `level` parameters to align the input when performing the `where`.

In [202]: `df2 = df.copy()`

(continues on next page)

(continued from previous page)

In [203]: `df2.where(df2 > 0, df2['A'], axis='index')`

Out[203]:

	A	B	C	D
2000-01-01	-2.104139	-2.104139	0.485855	0.245166
2000-01-02	-0.352480	0.390389	-0.352480	1.655824
2000-01-03	-0.864883	0.299674	-0.864883	0.281059
2000-01-04	0.846958	0.846958	0.600705	0.846958
2000-01-05	0.669692	0.669692	0.669692	0.342416
2000-01-06	0.868584	0.868584	2.297780	0.868584
2000-01-07	-2.670153	-2.670153	0.168904	-2.670153
2000-01-08	0.801196	1.392071	0.801196	0.801196

This is equivalent to (but faster than) the following.

In [204]: `df2 = df.copy()`

In [205]: `df.apply(lambda x, y: x.where(x > 0, y), y=df['A'])`

Out[205]:

	A	B	C	D
2000-01-01	-2.104139	-2.104139	0.485855	0.245166
2000-01-02	-0.352480	0.390389	-0.352480	1.655824
2000-01-03	-0.864883	0.299674	-0.864883	0.281059
2000-01-04	0.846958	0.846958	0.600705	0.846958
2000-01-05	0.669692	0.669692	0.669692	0.342416
2000-01-06	0.868584	0.868584	2.297780	0.868584
2000-01-07	-2.670153	-2.670153	0.168904	-2.670153
2000-01-08	0.801196	1.392071	0.801196	0.801196

`where` can accept a callable as condition and `other` arguments. The function must be with one argument (the calling Series or DataFrame) and that returns valid output as condition and `other` argument.

In [206]: `df3 = pd.DataFrame({'A': [1, 2, 3],
.....: 'B': [4, 5, 6],
.....: 'C': [7, 8, 9]})`

In [207]: `df3.where(lambda x: x > 4, lambda x: x + 10)`

Out[207]:

	A	B	C
0	11	14	7
1	12	5	8
2	13	6	9

Mask

`mask()` is the inverse boolean operation of `where`.

```
In [208]: s.mask(s >= 0)
```

```
Out[208]:
```

```
4    NaN  
3    NaN

```

2.5.16 Setting with enlargement conditionally using `numpy()`

An alternative to `where()` is to use `numpy.where()`. Combined with setting a new column, you can use it to enlarge a DataFrame where the values are determined conditionally.

Consider you have two choices to choose from in the following DataFrame. And you want to set a new column color to 'green' when the second column has 'Z'. You can do the following:

```
In [210]: df = pd.DataFrame({'col1': list('ABBC'), 'col2': list('ZZXY')})
```

```
In [211]: df['color'] = np.where(df['col2'] == 'Z', 'green', 'red')
```

```
In [212]: df
```

```
Out[212]:
```

```
   col1  col2  color  
0     A     Z  green  
1     B     Z  green  
2     B     X   red  
3     C     Y   red
```

If you have multiple conditions, you can use `numpy.select()` to achieve that. Say corresponding to three conditions there are three choice of colors, with a fourth color as a fallback, you can do the following.

```
In [213]: conditions = [  
.....:     (df['col2'] == 'Z') & (df['col1'] == 'A'),  
.....:     (df['col2'] == 'Z') & (df['col1'] == 'B'),  
.....:     (df['col1'] == 'B')  
.....:]
```

(continues on next page)

(continued from previous page)

```
.....:

In [214]: choices = ['yellow', 'blue', 'purple']

In [215]: df['color'] = np.select(conditions, choices, default='black')

In [216]: df
Out[216]:
   col1  col2    color
0     A     Z  yellow
1     B     Z    blue
2     B     X  purple
3     C     Y  black
```

2.5.17 The query() Method

DataFrame objects have a `query()` method that allows selection using an expression.

You can get the value of the frame where column b has values between the values of columns a and c. For example:

```
In [217]: n = 10

In [218]: df = pd.DataFrame(np.random.rand(n, 3), columns=list('abc'))

In [219]: df
Out[219]:
       a        b        c
0  0.438921  0.118680  0.863670
1  0.138138  0.577363  0.686602
2  0.595307  0.564592  0.520630
3  0.913052  0.926075  0.616184
4  0.078718  0.854477  0.898725
5  0.076404  0.523211  0.591538
6  0.792342  0.216974  0.564056
7  0.397890  0.454131  0.915716
8  0.074315  0.437913  0.019794
9  0.559209  0.502065  0.026437

# pure python
In [220]: df[(df['a'] < df['b']) & (df['b'] < df['c'])]
Out[220]:
       a        b        c
1  0.138138  0.577363  0.686602
4  0.078718  0.854477  0.898725
5  0.076404  0.523211  0.591538
7  0.397890  0.454131  0.915716

# query
In [221]: df.query('(a < b) & (b < c)')
Out[221]:
       a        b        c
```

(continues on next page)

(continued from previous page)

```
1  0.138138  0.577363  0.686602
4  0.078718  0.854477  0.898725
5  0.076404  0.523211  0.591538
7  0.397890  0.454131  0.915716
```

Do the same thing but fall back on a named index if there is no column with the name a.

```
In [222]: df = pd.DataFrame(np.random.randint(n / 2, size=(n, 2)), columns=list('bc'))
```

```
In [223]: df.index.name = 'a'
```

```
In [224]: df
```

```
Out[224]:
```

```
   b   c
a
0  0   4
1  0   1
2  3   4
3  4   3
4  1   4
5  0   3
6  0   1
7  3   4
8  2   3
9  1   1
```

```
In [225]: df.query('a < b and b < c')
```

```
Out[225]:
```

```
   b   c
a
2  3   4
```

If instead you don't want to or cannot name your index, you can use the name `index` in your query expression:

```
In [226]: df = pd.DataFrame(np.random.randint(n, size=(n, 2)), columns=list('bc'))
```

```
In [227]: df
```

```
Out[227]:
```

```
   b   c
0  3   1
1  3   0
2  5   6
3  5   2
4  7   4
5  0   1
6  2   5
7  0   1
8  6   0
9  7   9
```

```
In [228]: df.query('index < b < c')
```

```
Out[228]:
```

(continues on next page)

(continued from previous page)

b	c
2	5
6	

Note: If the name of your index overlaps with a column name, the column name is given precedence. For example,

```
In [229]: df = pd.DataFrame({'a': np.random.randint(5, size=5)})
```

```
In [230]: df.index.name = 'a'
```

```
In [231]: df.query('a > 2') # uses the column 'a', not the index
```

```
Out[231]:
```

a	
a	
1	3
3	3

You can still use the index in a query expression by using the special identifier ‘index’:

```
In [232]: df.query('index > 2')
```

```
Out[232]:
```

a	
a	
3	3
4	2

If for some reason you have a column named `index`, then you can refer to the index as `ilevel_0` as well, but at this point you should consider renaming your columns to something less ambiguous.

MultiIndex query() Syntax

You can also use the levels of a DataFrame with a `MultiIndex` as if they were columns in the frame:

```
In [233]: n = 10
```

```
In [234]: colors = np.random.choice(['red', 'green'], size=n)
```

```
In [235]: foods = np.random.choice(['eggs', 'ham'], size=n)
```

```
In [236]: colors
```

```
Out[236]:
```

```
array(['red', 'red', 'red', 'green', 'green', 'green', 'green', 'green',
       'green', 'green'], dtype='<U5')
```

```
In [237]: foods
```

```
Out[237]:
```

```
array(['ham', 'ham', 'eggs', 'eggs', 'eggs', 'ham', 'ham', 'eggs', 'eggs',
       'eggs'], dtype='<U4')
```

```
In [238]: index = pd.MultiIndex.from_arrays([colors, foods], names=['color', 'food'])
```

(continues on next page)

(continued from previous page)

```
In [239]: df = pd.DataFrame(np.random.randn(n, 2), index=index)
```

```
In [240]: df
```

```
Out[240]:
```

```
          0         1  
color food  
red   ham  0.194889 -0.381994  
      ham  0.318587  2.089075  
    eggs -0.728293 -0.090255  
green eggs -0.748199  1.318931  
    eggs -2.029766  0.792652  
    ham  0.461007 -0.542749  
    ham -0.305384 -0.479195  
    eggs  0.095031 -0.270099  
    eggs -0.707140 -0.773882  
    eggs  0.229453  0.304418
```

```
In [241]: df.query('color == "red"')
```

```
Out[241]:
```

```
          0         1  
color food  
red   ham  0.194889 -0.381994  
      ham  0.318587  2.089075  
    eggs -0.728293 -0.090255
```

If the levels of the MultiIndex are unnamed, you can refer to them using special names:

```
In [242]: df.index.names = [None, None]
```

```
In [243]: df
```

```
Out[243]:
```

```
          0         1  
red   ham  0.194889 -0.381994  
      ham  0.318587  2.089075  
    eggs -0.728293 -0.090255  
green eggs -0.748199  1.318931  
    eggs -2.029766  0.792652  
    ham  0.461007 -0.542749  
    ham -0.305384 -0.479195  
    eggs  0.095031 -0.270099  
    eggs -0.707140 -0.773882  
    eggs  0.229453  0.304418
```

```
In [244]: df.query('ilevel_0 == "red"')
```

```
Out[244]:
```

```
          0         1  
red ham  0.194889 -0.381994  
    ham  0.318587  2.089075  
  eggs -0.728293 -0.090255
```

The convention is `ilevel_0`, which means “index level 0” for the 0th level of the `index`.

query() Use Cases

A use case for `query()` is when you have a collection of `DataFrame` objects that have a subset of column names (or index levels/names) in common. You can pass the same query to both frames *without* having to specify which frame you're interested in querying

```
In [245]: df = pd.DataFrame(np.random.rand(n, 3), columns=list('abc'))
```

```
In [246]: df
```

```
Out[246]:
```

	a	b	c
0	0.224283	0.736107	0.139168
1	0.302827	0.657803	0.713897
2	0.611185	0.136624	0.984960
3	0.195246	0.123436	0.627712
4	0.618673	0.371660	0.047902
5	0.480088	0.062993	0.185760
6	0.568018	0.483467	0.445289
7	0.309040	0.274580	0.587101
8	0.258993	0.477769	0.370255
9	0.550459	0.840870	0.304611

```
In [247]: df2 = pd.DataFrame(np.random.rand(n + 2, 3), columns=df.columns)
```

```
In [248]: df2
```

```
Out[248]:
```

	a	b	c
0	0.357579	0.229800	0.596001
1	0.309059	0.957923	0.965663
2	0.123102	0.336914	0.318616
3	0.526506	0.323321	0.860813
4	0.518736	0.486514	0.384724
5	0.190804	0.505723	0.614533
6	0.891939	0.623977	0.676639
7	0.480559	0.378528	0.460858
8	0.420223	0.136404	0.141295
9	0.732206	0.419540	0.604675
10	0.604466	0.848974	0.896165
11	0.589168	0.920046	0.732716

```
In [249]: expr = '0.0 <= a <= c <= 0.5'
```

```
In [250]: map(lambda frame: frame.query(expr), [df, df2])
```

```
Out[250]: <map at 0x7f54a647bdf0>
```

query() Python versus pandas Syntax Comparison

Full numpy-like syntax:

```
In [251]: df = pd.DataFrame(np.random.randint(n, size=(n, 3)), columns=list('abc'))
```

```
In [252]: df
```

```
Out[252]:
```

```
   a   b   c  
0  7   8   9  
1  1   0   7  
2  2   7   2  
3  6   2   2  
4  2   6   3  
5  3   8   2  
6  1   7   2  
7  5   1   5  
8  9   8   0  
9  1   5   0
```

```
In [253]: df.query('(a < b) & (b < c)')
```

```
Out[253]:
```

```
   a   b   c  
0  7   8   9
```

```
In [254]: df[(df['a'] < df['b']) & (df['b'] < df['c'])]
```

```
Out[254]:
```

```
   a   b   c  
0  7   8   9
```

Slightly nicer by removing the parentheses (comparison operators bind tighter than & and |):

```
In [255]: df.query('a < b & b < c')
```

```
Out[255]:
```

```
   a   b   c  
0  7   8   9
```

Use English instead of symbols:

```
In [256]: df.query('a < b and b < c')
```

```
Out[256]:
```

```
   a   b   c  
0  7   8   9
```

Pretty close to how you might write it on paper:

```
In [257]: df.query('a < b < c')
```

```
Out[257]:
```

```
   a   b   c  
0  7   8   9
```

The `in` and `not in` operators

`query()` also supports special use of Python's `in` and `not in` comparison operators, providing a succinct syntax for calling the `isin` method of a Series or DataFrame.

```
# get all rows where columns "a" and "b" have overlapping values
In [258]: df = pd.DataFrame({'a': list('aabbcdddeeff'), 'b': list('aaaabbbbcccc'),
.....:                               'c': np.random.randint(5, size=12),
.....:                               'd': np.random.randint(9, size=12)})
```

In [259]: `df`

Out[259]:

	a	b	c	d
0	a	a	2	6
1	a	a	4	7
2	b	a	1	6
3	b	a	2	1
4	c	b	3	6
5	c	b	0	2
6	d	b	3	3
7	d	b	2	1
8	e	c	4	3
9	e	c	2	0
10	f	c	0	6
11	f	c	1	2

In [260]: `df.query('a in b')`

Out[260]:

	a	b	c	d
0	a	a	2	6
1	a	a	4	7
2	b	a	1	6
3	b	a	2	1
4	c	b	3	6
5	c	b	0	2

How you'd do it in pure Python

In [261]: `df[df['a'].isin(df['b'])]`

Out[261]:

	a	b	c	d
0	a	a	2	6
1	a	a	4	7
2	b	a	1	6
3	b	a	2	1
4	c	b	3	6
5	c	b	0	2

In [262]: `df.query('a not in b')`

Out[262]:

	a	b	c	d
6	d	b	3	3
7	d	b	2	1

(continues on next page)

(continued from previous page)

```

8   e  c  4  3
9   e  c  2  0
10  f  c  0  6
11  f  c  1  2

# pure Python
In [263]: df[~df['a'].isin(df['b'])]
Out[263]:
   a  b  c  d
6  d  b  3  3
7  d  b  2  1
8  e  c  4  3
9  e  c  2  0
10 f  c  0  6
11 f  c  1  2

```

You can combine this with other expressions for very succinct queries:

```

# rows where cols a and b have overlapping values
# and col c's values are less than col d's
In [264]: df.query('a in b and c < d')
Out[264]:
   a  b  c  d
0  a  a  2  6
1  a  a  4  7
2  b  a  1  6
4  c  b  3  6
5  c  b  0  2

# pure Python
In [265]: df[df['b'].isin(df['a'])] & (df['c'] < df['d'])
Out[265]:
   a  b  c  d
0  a  a  2  6
1  a  a  4  7
2  b  a  1  6
4  c  b  3  6
5  c  b  0  2
10 f  c  0  6
11 f  c  1  2

```

Note: Note that `in` and `not in` are evaluated in Python, since `numexpr` has no equivalent of this operation. However, **only the `in/not in` expression itself** is evaluated in vanilla Python. For example, in the expression

```
df.query('a in b + c + d')
```

`(b + c + d)` is evaluated by `numexpr` and *then* the `in` operation is evaluated in plain Python. In general, any operations that can be evaluated using `numexpr` will be.

Special use of the == operator with list objects

Comparing a list of values to a column using ==/!= works similarly to `in/not in`.

```
In [266]: df.query('b == ["a", "b", "c"]')
```

```
Out[266]:
```

	a	b	c	d
0	a	a	2	6
1	a	a	4	7
2	b	a	1	6
3	b	a	2	1
4	c	b	3	6
5	c	b	0	2
6	d	b	3	3
7	d	b	2	1
8	e	c	4	3
9	e	c	2	0
10	f	c	0	6
11	f	c	1	2

```
# pure Python
```

```
In [267]: df[df['b'].isin(["a", "b", "c"])]
```

```
Out[267]:
```

	a	b	c	d
0	a	a	2	6
1	a	a	4	7
2	b	a	1	6
3	b	a	2	1
4	c	b	3	6
5	c	b	0	2
6	d	b	3	3
7	d	b	2	1
8	e	c	4	3
9	e	c	2	0
10	f	c	0	6
11	f	c	1	2

```
In [268]: df.query('c == [1, 2]')
```

```
Out[268]:
```

	a	b	c	d
0	a	a	2	6
2	b	a	1	6
3	b	a	2	1
7	d	b	2	1
9	e	c	2	0
11	f	c	1	2

```
In [269]: df.query('c != [1, 2]')
```

```
Out[269]:
```

	a	b	c	d
1	a	a	4	7
4	c	b	3	6
5	c	b	0	2

(continues on next page)

(continued from previous page)

```

6   d   b   3   3
8   e   c   4   3
10  f   c   0   6

# using in/not in
In [270]: df.query('[1, 2] in c')
Out[270]:
   a   b   c   d
0   a   a   2   6
2   b   a   1   6
3   b   a   2   1
7   d   b   2   1
9   e   c   2   0
11  f   c   1   2

In [271]: df.query('[1, 2] not in c')
Out[271]:
   a   b   c   d
1   a   a   4   7
4   c   b   3   6
5   c   b   0   2
6   d   b   3   3
8   e   c   4   3
10  f   c   0   6

# pure Python
In [272]: df[df['c'].isin([1, 2])]
Out[272]:
   a   b   c   d
0   a   a   2   6
2   b   a   1   6
3   b   a   2   1
7   d   b   2   1
9   e   c   2   0
11  f   c   1   2

```

Boolean operators

You can negate boolean expressions with the word `not` or the `~` operator.

```

In [273]: df = pd.DataFrame(np.random.rand(n, 3), columns=list('abc'))
In [274]: df['bools'] = np.random.rand(len(df)) > 0.5
In [275]: df.query('~bools')
Out[275]:
           a           b           c  bools
2  0.697753  0.212799  0.329209  False
7  0.275396  0.691034  0.826619  False
8  0.190649  0.558748  0.262467  False

```

(continues on next page)

(continued from previous page)

```
In [276]: df.query('not bools')
Out[276]:
      a      b      c  bools
2  0.697753  0.212799  0.329209  False
7  0.275396  0.691034  0.826619  False
8  0.190649  0.558748  0.262467  False

In [277]: df.query('not bools') == df[~df['bools']]
Out[277]:
      a      b      c  bools
2  True  True  True  True
7  True  True  True  True
8  True  True  True  True
```

Of course, expressions can be arbitrarily complex too:

```
# short query syntax
In [278]: shorter = df.query('a < b < c and (not bools) or bools > 2')

# equivalent in pure Python
In [279]: longer = df[(df['a'] < df['b']) & (df['b'] < df['c']) & (~df['bools']) | (df['bools'] > 2)]

In [280]: shorter
Out[280]:
      a      b      c  bools
7  0.275396  0.691034  0.826619  False

In [281]: longer
Out[281]:
      a      b      c  bools
7  0.275396  0.691034  0.826619  False

In [282]: shorter == longer
Out[282]:
      a      b      c  bools
7  True  True  True  True
```

Performance of query()

`DataFrame.query()` using `numexpr` is slightly faster than Python for large frames.

Note: You will only see the performance benefits of using the `numexpr` engine with `DataFrame.query()` if your frame has more than approximately 200,000 rows.

This plot was created using a `DataFrame` with 3 columns each containing floating point values generated using `numpy.random.randn()`.

2.5.18 Duplicate data

If you want to identify and remove duplicate rows in a DataFrame, there are two methods that will help: `duplicated` and `drop_duplicates`. Each takes as an argument the columns to use to identify duplicated rows.

- `duplicated` returns a boolean vector whose length is the number of rows, and which indicates whether a row is duplicated.
- `drop_duplicates` removes duplicate rows.

By default, the first observed row of a duplicate set is considered unique, but each method has a `keep` parameter to specify targets to be kept.

- `keep='first'` (default): mark / drop duplicates except for the first occurrence.
- `keep='last'`: mark / drop duplicates except for the last occurrence.
- `keep=False`: mark / drop all duplicates.

```
In [283]: df2 = pd.DataFrame({'a': ['one', 'one', 'two', 'two', 'two', 'three', 'four'],
.....:                   'b': ['x', 'y', 'x', 'y', 'x', 'x', 'x'],
.....:                   'c': np.random.randn(7)})
.....:
```

```
In [284]: df2
Out[284]:
      a   b       c
0   one  x -1.067137
1   one  y  0.309500
2   two  x -0.211056
3   two  y -1.842023
4   two  x -0.390820
5  three  x -1.964475
6   four  x  1.298329
```

```
In [285]: df2.duplicated('a')
Out[285]:
0    False
1     True
2    False
3     True
4     True
5    False
6    False
dtype: bool
```

```
In [286]: df2.duplicated('a', keep='last')
Out[286]:
0     True
1    False
2     True
3     True
4    False
5    False
6    False
dtype: bool
```

(continues on next page)

(continued from previous page)

```
In [287]: df2.duplicated('a', keep=False)
```

```
Out[287]:
```

```
0    True  
1    True  
2    True  
3    True  
4    True  
5   False  
6   False  
dtype: bool
```

```
In [288]: df2.drop_duplicates('a')
```

```
Out[288]:
```

```
      a   b       c  
0   one  x -1.067137  
2   two  x -0.211056  
5 three  x -1.964475  
6 four  x  1.298329
```

```
In [289]: df2.drop_duplicates('a', keep='last')
```

```
Out[289]:
```

```
      a   b       c  
1   one  y  0.309500  
4   two  x -0.390820  
5 three  x -1.964475  
6 four  x  1.298329
```

```
In [290]: df2.drop_duplicates('a', keep=False)
```

```
Out[290]:
```

```
      a   b       c  
5 three  x -1.964475  
6 four  x  1.298329
```

Also, you can pass a list of columns to identify duplications.

```
In [291]: df2.duplicated(['a', 'b'])
```

```
Out[291]:
```

```
0    False  
1    False  
2    False  
3    False  
4    True  
5    False  
6    False  
dtype: bool
```

```
In [292]: df2.drop_duplicates(['a', 'b'])
```

```
Out[292]:
```

```
      a   b       c  
0   one  x -1.067137  
1   one  y  0.309500
```

(continues on next page)

(continued from previous page)

```
2    two  x -0.211056
3    two  y -1.842023
5  three  x -1.964475
6   four  x  1.298329
```

To drop duplicates by index value, use `Index.duplicated` then perform slicing. The same set of options are available for the `keep` parameter.

```
In [293]: df3 = pd.DataFrame({'a': np.arange(6),
.....:                      'b': np.random.randn(6)},
.....:                      index=['a', 'a', 'b', 'c', 'b', 'a'])
```

```
In [294]: df3
```

```
Out[294]:
      a          b
a  0  1.440455
a  1  2.456086
b  2  1.038402
c  3 -0.894409
b  4  0.683536
a  5  3.082764
```

```
In [295]: df3.index.duplicated()
```

```
Out[295]: array([False,  True, False, False,  True,  True])
```

```
In [296]: df3[~df3.index.duplicated()]
```

```
Out[296]:
      a          b
a  0  1.440455
b  2  1.038402
c  3 -0.894409
```

```
In [297]: df3[~df3.index.duplicated(keep='last')]
```

```
Out[297]:
      a          b
c  3 -0.894409
b  4  0.683536
a  5  3.082764
```

```
In [298]: df3[~df3.index.duplicated(keep=False)]
```

```
Out[298]:
      a          b
c  3 -0.894409
```

2.5.19 Dictionary-like get() method

Each of Series or DataFrame have a get method which can return a default value.

```
In [299]: s = pd.Series([1, 2, 3], index=['a', 'b', 'c'])
```

```
In [300]: s.get('a') # equivalent to s['a']
```

```
Out[300]: 1
```

```
In [301]: s.get('x', default=-1)
```

```
Out[301]: -1
```

2.5.20 Looking up values by index/column labels

Sometimes you want to extract a set of values given a sequence of row labels and column labels, this can be achieved by pandas.factorize and NumPy indexing. For instance:

```
In [302]: df = pd.DataFrame({'col': ["A", "A", "B", "B"],  
.....: 'A': [80, 23, np.nan, 22],  
.....: 'B': [80, 55, 76, 67]})  
.....:
```

```
In [303]: df
```

```
Out[303]:  
      col      A      B  
0     A    80.0    80  
1     A    23.0    55  
2     B    NaN    76  
3     B    22.0    67
```

```
In [304]: idx, cols = pd.factorize(df['col'])
```

```
In [305]: df.reindex(cols, axis=1).to_numpy()[np.arange(len(df)), idx]
```

```
Out[305]: array([80., 23., 76., 67.])
```

Formerly this could be achieved with the dedicated DataFrame.lookup method which was deprecated in version 1.2.0.

2.5.21 Index objects

The pandas `Index` class and its subclasses can be viewed as implementing an *ordered multiset*. Duplicates are allowed. However, if you try to convert an `Index` object with duplicate entries into a `set`, an exception will be raised.

`Index` also provides the infrastructure necessary for lookups, data alignment, and reindexing. The easiest way to create an `Index` directly is to pass a list or other sequence to `Index`:

```
In [306]: index = pd.Index(['e', 'd', 'a', 'b'])
```

```
In [307]: index
```

```
Out[307]: Index(['e', 'd', 'a', 'b'], dtype='object')
```

```
In [308]: 'd' in index
```

```
Out[308]: True
```

You can also pass a `name` to be stored in the index:

```
In [309]: index = pd.Index(['e', 'd', 'a', 'b'], name='something')

In [310]: index.name
Out[310]: 'something'
```

The name, if set, will be shown in the console display:

```
In [311]: index = pd.Index(list(range(5)), name='rows')

In [312]: columns = pd.Index(['A', 'B', 'C'], name='cols')

In [313]: df = pd.DataFrame(np.random.randn(5, 3), index=index, columns=columns)

In [314]: df
Out[314]:
   cols      A      B      C
rows
0    1.295989 -1.051694  1.340429
1   -2.366110  0.428241  0.387275
2    0.433306  0.929548  0.278094
3    2.154730 -0.315628  0.264223
4    1.126818  1.132290 -0.353310

In [315]: df['A']
Out[315]:
rows
0    1.295989
1   -2.366110
2    0.433306
3    2.154730
4    1.126818
Name: A, dtype: float64
```

Setting metadata

Indexes are “mostly immutable”, but it is possible to set and change their `name` attribute. You can use the `rename`, `set_names` to set these attributes directly, and they default to returning a copy.

See [Advanced Indexing](#) for usage of MultiIndexes.

```
In [316]: ind = pd.Index([1, 2, 3])

In [317]: ind.rename("apple")
Out[317]: Int64Index([1, 2, 3], dtype='int64', name='apple')

In [318]: ind
Out[318]: Int64Index([1, 2, 3], dtype='int64')

In [319]: ind.set_names(["apple"], inplace=True)

In [320]: ind.name = "bob"
```

(continues on next page)

(continued from previous page)

```
In [321]: ind
Out[321]: Int64Index([1, 2, 3], dtype='int64', name='bob')
```

`set_names`, `set_levels`, and `set_codes` also take an optional `level` argument

```
In [322]: index = pd.MultiIndex.from_product([range(3), ['one', 'two']], names=['first',
   ↪ 'second'])
```

```
In [323]: index
Out[323]:
MultiIndex([(0, 'one'),
            (0, 'two'),
            (1, 'one'),
            (1, 'two'),
            (2, 'one'),
            (2, 'two')], names=['first', 'second'])
```

```
In [324]: index.levels[1]
Out[324]: Index(['one', 'two'], dtype='object', name='second')
```

```
In [325]: index.set_levels(["a", "b"], level=1)
Out[325]:
MultiIndex([(0, 'a'),
            (0, 'b'),
            (1, 'a'),
            (1, 'b'),
            (2, 'a'),
            (2, 'b')], names=['first', 'second'])
```

Set operations on Index objects

The two main operations are `union` and `intersection`. Difference is provided via the `.difference()` method.

```
In [326]: a = pd.Index(['c', 'b', 'a'])
```

```
In [327]: b = pd.Index(['c', 'e', 'd'])
```

```
In [328]: a.difference(b)
Out[328]: Index(['a', 'b'], dtype='object')
```

Also available is the `symmetric_difference` operation, which returns elements that appear in either `idx1` or `idx2`, but not in both. This is equivalent to the `Index` created by `idx1.difference(idx2).union(idx2.difference(idx1))`, with duplicates dropped.

```
In [329]: idx1 = pd.Index([1, 2, 3, 4])
```

```
In [330]: idx2 = pd.Index([2, 3, 4, 5])
```

(continues on next page)

(continued from previous page)

```
In [331]: idx1.symmetric_difference(idx2)
Out[331]: Int64Index([1, 5], dtype='int64')
```

Note: The resulting index from a set operation will be sorted in ascending order.

When performing `Index.union()` between indexes with different dtypes, the indexes must be cast to a common dtype. Typically, though not always, this is object dtype. The exception is when performing a union between integer and float data. In this case, the integer values are converted to float

```
In [332]: idx1 = pd.Index([0, 1, 2])
In [333]: idx2 = pd.Index([0.5, 1.5])
In [334]: idx1.union(idx2)
Out[334]: Float64Index([0.0, 0.5, 1.0, 1.5, 2.0], dtype='float64')
```

Missing values

Important: Even though Index can hold missing values (NaN), it should be avoided if you do not want any unexpected results. For example, some operations exclude missing values implicitly.

`Index.fillna` fills missing values with specified scalar value.

```
In [335]: idx1 = pd.Index([1, np.nan, 3, 4])
In [336]: idx1
Out[336]: Float64Index([1.0, nan, 3.0, 4.0], dtype='float64')

In [337]: idx1.fillna(2)
Out[337]: Float64Index([1.0, 2.0, 3.0, 4.0], dtype='float64')

In [338]: idx2 = pd.DatetimeIndex([pd.Timestamp('2011-01-01'),
.....:                 pd.NaT,
.....:                 pd.Timestamp('2011-01-03')])
.....:

In [339]: idx2
Out[339]: DatetimeIndex(['2011-01-01', 'NaT', '2011-01-03'], dtype='datetime64[ns]', freq=None)

In [340]: idx2.fillna(pd.Timestamp('2011-01-02'))
Out[340]: DatetimeIndex(['2011-01-01', '2011-01-02', '2011-01-03'], dtype='datetime64[ns]', freq=None)
```

2.5.22 Set / reset index

Occasionally you will load or create a data set into a DataFrame and want to add an index after you've already done so. There are a couple of different ways.

Set an index

DataFrame has a `set_index()` method which takes a column name (for a regular Index) or a list of column names (for a MultiIndex). To create a new, re-indexed DataFrame:

```
In [341]: data
Out[341]:
      a    b    c    d
0  bar  one   z  1.0
1  bar  two   y  2.0
2  foo  one   x  3.0
3  foo  two   w  4.0

In [342]: indexed1 = data.set_index('c')

In [343]: indexed1
Out[343]:
      a    b    d
c
z  bar  one  1.0
y  bar  two  2.0
x  foo  one  3.0
w  foo  two  4.0

In [344]: indexed2 = data.set_index(['a', 'b'])

In [345]: indexed2
Out[345]:
      c    d
a    b
bar one   z  1.0
      two   y  2.0
foo one   x  3.0
      two   w  4.0
```

The `append` keyword option allow you to keep the existing index and append the given columns to a MultiIndex:

```
In [346]: frame = data.set_index('c', drop=False)

In [347]: frame = frame.set_index(['a', 'b'], append=True)

In [348]: frame
Out[348]:
      c    d
c a    b
z bar one   z  1.0
y bar two   y  2.0
```

(continues on next page)

(continued from previous page)

```
x  foo  one   x  3.0
w  foo  two   w  4.0
```

Other options in `set_index` allow you not drop the index columns or to add the index in-place (without creating a new object):

```
In [349]: data.set_index('c', drop=False)
Out[349]:
      a    b    c    d
c
z  bar  one   z  1.0
y  bar  two   y  2.0
x  foo  one   x  3.0
w  foo  two   w  4.0

In [350]: data.set_index(['a', 'b'], inplace=True)

In [351]: data
Out[351]:
      c    d
a    b
bar one   z  1.0
      two   y  2.0
foo one   x  3.0
      two   w  4.0
```

Reset the index

As a convenience, there is a new function on DataFrame called `reset_index()` which transfers the index values into the DataFrame's columns and sets a simple integer index. This is the inverse operation of `set_index()`.

```
In [352]: data
Out[352]:
      c    d
a    b
bar one   z  1.0
      two   y  2.0
foo one   x  3.0
      two   w  4.0

In [353]: data.reset_index()
Out[353]:
      a    b    c    d
0  bar  one   z  1.0
1  bar  two   y  2.0
2  foo  one   x  3.0
3  foo  two   w  4.0
```

The output is more similar to a SQL table or a record array. The names for the columns derived from the index are the ones stored in the `names` attribute.

You can use the `level` keyword to remove only a portion of the index:

```
In [354]: frame
```

```
Out[354]:
```

```
      c      d  
c a    b  
z bar one  z  1.0  
y bar two  y  2.0  
x foo one  x  3.0  
w foo two  w  4.0
```

```
In [355]: frame.reset_index(level=1)
```

```
Out[355]:
```

```
      a      c      d  
c b  
z one  bar   z  1.0  
y two  bar   y  2.0  
x one  foo   x  3.0  
w two  foo   w  4.0
```

`reset_index` takes an optional parameter `drop` which if true simply discards the index, instead of putting index values in the DataFrame's columns.

Adding an ad hoc index

If you create an index yourself, you can just assign it to the `index` field:

```
data.index = index
```

2.5.23 Returning a view versus a copy

When setting values in a pandas object, care must be taken to avoid what is called `chained indexing`. Here is an example.

```
In [356]: dfmi = pd.DataFrame([list('abcd'),  
.....:           list('efgh'),  
.....:           list('ijkl'),  
.....:           list('mnop')],  
.....:           columns=pd.MultiIndex.from_product([[['one', 'two'],  
.....:                                         ['first', 'second']]])  
.....:
```

```
In [357]: dfmi
```

```
Out[357]:
```

```
      one          two  
      first second first second  
0     a       b     c       d  
1     e       f     g       h  
2     i       j     k       l  
3     m       n     o       p
```

Compare these two access methods:

```
In [358]: dfmi['one']['second']
```

```
Out[358]:
```

```
0    b
1    f
2    j
3    n
Name: second, dtype: object
```

```
In [359]: dfmi.loc[:, ('one', 'second')]
```

```
Out[359]:
```

```
0    b
1    f
2    j
3    n
Name: (one, second), dtype: object
```

These both yield the same results, so which should you use? It is instructive to understand the order of operations on these and why method 2 (.loc) is much preferred over method 1 (chained []).

`dfmi['one']` selects the first level of the columns and returns a DataFrame that is singly-indexed. Then another Python operation `dfmi_with_one['second']` selects the series indexed by 'second'. This is indicated by the variable `dfmi_with_one` because pandas sees these operations as separate events. e.g. separate calls to `__getitem__`, so it has to treat them as linear operations, they happen one after another.

Contrast this to `df.loc[:,('one','second')]` which passes a nested tuple of `(slice(None), ('one', 'second'))` to a single call to `__getitem__`. This allows pandas to deal with this as a single entity. Furthermore this order of operations *can* be significantly faster, and allows one to index *both* axes if so desired.

Why does assignment fail when using chained indexing?

The problem in the previous section is just a performance issue. What's up with the `SettingWithCopy` warning? We don't **usually** throw warnings around when you do something that might cost a few extra milliseconds!

But it turns out that assigning to the product of chained indexing has inherently unpredictable results. To see this, think about how the Python interpreter executes this code:

```
dfmi.loc[:, ('one', 'second')] = value
# becomes
dfmi.loc.__setitem__((slice(None), ('one', 'second')), value)
```

But this code is handled differently:

```
dfmi['one']['second'] = value
# becomes
dfmi.__getitem__('one').__setitem__('second', value)
```

See that `__getitem__` in there? Outside of simple cases, it's very hard to predict whether it will return a view or a copy (it depends on the memory layout of the array, about which pandas makes no guarantees), and therefore whether the `__setitem__` will modify `dfmi` or a temporary object that gets thrown out immediately afterward. **That's** what `SettingWithCopy` is warning you about!

Note: You may be wondering whether we should be concerned about the `loc` property in the first example. But

`dfmi.loc` is guaranteed to be `dfmi` itself with modified indexing behavior, so `dfmi.loc.__getitem__ / dfmi.loc.__setitem__` operate on `dfmi` directly. Of course, `dfmi.loc.__getitem__(idx)` may be a view or a copy of `dfmi`.

Sometimes a `SettingWithCopy` warning will arise at times when there's no obvious chained indexing going on. These are the bugs that `SettingWithCopy` is designed to catch! pandas is probably trying to warn you that you've done this:

```
def do_something(df):
    foo = df[['bar', 'baz']] # Is foo a view? A copy? Nobody knows!
    # ... many lines here ...
    # We don't know whether this will modify df or not!
    foo['quux'] = value
    return foo
```

Yikes!

Evaluation order matters

When you use chained indexing, the order and type of the indexing operation partially determine whether the result is a slice into the original object, or a copy of the slice.

pandas has the `SettingWithCopyWarning` because assigning to a copy of a slice is frequently not intentional, but a mistake caused by chained indexing returning a copy where a slice was expected.

If you would like pandas to be more or less trusting about assignment to a chained indexing expression, you can set the `option mode.chained_assignment` to one of these values:

- 'warn', the default, means a `SettingWithCopyWarning` is printed.
- 'raise' means pandas will raise a `SettingWithCopyException` you have to deal with.
- 'None' will suppress the warnings entirely.

```
In [360]: dfb = pd.DataFrame({'a': ['one', 'one', 'two',
.....:                               'three', 'two', 'one', 'six'],
.....:                               'c': np.arange(7)})
.....:

# This will show the SettingWithCopyWarning
# but the frame values will be set
In [361]: dfb['c'][dfb['a'].str.startswith('o')] = 42
```

This however is operating on a copy and will not work.

```
>>> pd.set_option('mode.chained_assignment','warn')
>>> dfb[dfb['a'].str.startswith('o')]['c'] = 42
Traceback (most recent call last)
...
SettingWithCopyWarning:
  A value is trying to be set on a copy of a slice from a DataFrame.
  Try using .loc[row_index,col_indexer] = value instead
```

A chained assignment can also crop up in setting in a mixed dtype frame.

Note: These setting rules apply to all of `.loc/.iloc`.

The following is the recommended access method using `.loc` for multiple items (using `mask`) and a single item using a fixed index:

```
In [362]: dfc = pd.DataFrame({'a': ['one', 'one', 'two',
.....:                 'three', 'two', 'one', 'six'],
.....:                 'c': np.arange(7)})

In [363]: dfd = dfc.copy()

# Setting multiple items using a mask
In [364]: mask = dfd['a'].str.startswith('o')

In [365]: dfd.loc[mask, 'c'] = 42

In [366]: dfd
Out[366]:
      a    c
0   one  42
1   one  42
2   two   2
3 three   3
4   two   4
5   one  42
6   six   6

# Setting a single item
In [367]: dfd = dfc.copy()

In [368]: dfd.loc[2, 'a'] = 11

In [369]: dfd
Out[369]:
      a    c
0   one  0
1   one  1
2    11  2
3 three  3
4   two  4
5   one  5
6   six  6
```

The following *can* work at times, but it is not guaranteed to, and therefore should be avoided:

```
In [370]: dfd = dfc.copy()

In [371]: dfd['a'][2] = 111

In [372]: dfd
Out[372]:
      a    c
0   one  0
1   one  1
2   111  2
```

(continues on next page)

(continued from previous page)

```
3  three  3
4    two  4
5    one  5
6    six  6
```

Last, the subsequent example will **not** work at all, and so should be avoided:

```
>>> pd.set_option('mode.chained_assignment','raise')
>>> dfd.loc[0]['a'] = 1111
Traceback (most recent call last)
...
SettingWithCopyException:
A value is trying to be set on a copy of a slice from a DataFrame.
Try using .loc[row_index,col_indexer] = value instead
```

Warning: The chained assignment warnings / exceptions are aiming to inform the user of a possibly invalid assignment. There may be false positives; situations where a chained assignment is inadvertently reported.

2.6 MultiIndex / advanced indexing

This section covers *indexing with a MultiIndex* and *other advanced indexing features*.

See the [Indexing and Selecting Data](#) for general indexing documentation.

Warning: Whether a copy or a reference is returned for a setting operation may depend on the context. This is sometimes called **chained assignment** and should be avoided. See [Returning a View versus Copy](#).

See the [cookbook](#) for some advanced strategies.

2.6.1 Hierarchical indexing (MultiIndex)

Hierarchical / Multi-level indexing is very exciting as it opens the door to some quite sophisticated data analysis and manipulation, especially for working with higher dimensional data. In essence, it enables you to store and manipulate data with an arbitrary number of dimensions in lower dimensional data structures like Series (1d) and DataFrame (2d).

In this section, we will show what exactly we mean by “hierarchical” indexing and how it integrates with all of the pandas indexing functionality described above and in prior sections. Later, when discussing [group by](#) and [pivoting and reshaping data](#), we’ll show non-trivial applications to illustrate how it aids in structuring data for analysis.

See the [cookbook](#) for some advanced strategies.

Creating a MultiIndex (hierarchical index) object

The `MultiIndex` object is the hierarchical analogue of the standard `Index` object which typically stores the axis labels in pandas objects. You can think of `MultiIndex` as an array of tuples where each tuple is unique. A `MultiIndex` can be created from a list of arrays (using `MultiIndex.from_arrays()`), an array of tuples (using `MultiIndex.from_tuples()`), a crossed set of iterables (using `MultiIndex.from_product()`), or a `DataFrame` (using `MultiIndex.from_frame()`). The `Index` constructor will attempt to return a `MultiIndex` when it is passed a list of tuples. The following examples demonstrate different ways to initialize `MultiIndex`es.

```
In [1]: arrays = [
...:     ["bar", "bar", "baz", "baz", "foo", "foo", "qux", "qux"],
...:     ["one", "two", "one", "two", "one", "two", "one", "two"],
...: ]
...:

In [2]: tuples = list(zip(*arrays))

In [3]: tuples
Out[3]:
[('bar', 'one'),
 ('bar', 'two'),
 ('baz', 'one'),
 ('baz', 'two'),
 ('foo', 'one'),
 ('foo', 'two'),
 ('qux', 'one'),
 ('qux', 'two')]

In [4]: index = pd.MultiIndex.from_tuples(tuples, names=["first", "second"])

In [5]: index
Out[5]:
MultiIndex([(bar', 'one'),
            ('bar', 'two'),
            ('baz', 'one'),
            ('baz', 'two'),
            ('foo', 'one'),
            ('foo', 'two'),
            ('qux', 'one'),
            ('qux', 'two')],
            names=['first', 'second'])

In [6]: s = pd.Series(np.random.randn(8), index=index)

In [7]: s
Out[7]:
first   second
bar      one      0.469112
              two     -0.282863
baz      one     -1.509059
              two     -1.135632
foo      one      1.212112
              two     -0.173215
```

(continues on next page)

(continued from previous page)

```
qux    one      0.119209
       two     -1.044236
dtype: float64
```

When you want every pairing of the elements in two iterables, it can be easier to use the `MultiIndex.from_product()` method:

```
In [8]: iterables = [["bar", "baz", "foo", "qux"], ["one", "two"]]
In [9]: pd.MultiIndex.from_product(iterables, names=["first", "second"])
Out[9]:
MultiIndex([('bar', 'one'),
            ('bar', 'two'),
            ('baz', 'one'),
            ('baz', 'two'),
            ('foo', 'one'),
            ('foo', 'two'),
            ('qux', 'one'),
            ('qux', 'two')],  
names=['first', 'second'])
```

You can also construct a MultiIndex from a DataFrame directly, using the method `MultiIndex.from_frame()`. This is a complementary method to `MultiIndex.to_frame()`.

```
In [10]: df = pd.DataFrame(  
.....:     [["bar", "one"], ["bar", "two"], ["foo", "one"], ["foo", "two"]],  
.....:     columns=["first", "second"],  
.....: )
.....:  
  
In [11]: pd.MultiIndex.from_frame(df)
Out[11]:
MultiIndex([('bar', 'one'),
            ('bar', 'two'),
            ('foo', 'one'),
            ('foo', 'two')],  
names=['first', 'second'])
```

As a convenience, you can pass a list of arrays directly into Series or DataFrame to construct a MultiIndex automatically:

```
In [12]: arrays = [
.....:     np.array(["bar", "bar", "baz", "baz", "foo", "foo", "qux", "qux"]),
.....:     np.array(["one", "two", "one", "two", "one", "two", "one", "two"]),
.....: ]
.....:  
  
In [13]: s = pd.Series(np.random.randn(8), index=arrays)  
  
In [14]: s
Out[14]:
bar    one    -0.861849
       two    -2.104569
```

(continues on next page)

(continued from previous page)

```
baz  one   -0.494929
     two    1.071804
foo  one    0.721555
     two   -0.706771
qux  one   -1.039575
     two    0.271860
dtype: float64
```

In [15]: df = pd.DataFrame(np.random.randn(8, 4), index=arrays)

In [16]: df

Out[16]:

	0	1	2	3
bar one	-0.424972	0.567020	0.276232	-1.087401
two	-0.673690	0.113648	-1.478427	0.524988
baz one	0.404705	0.577046	-1.715002	-1.039268
two	-0.370647	-1.157892	-1.344312	0.844885
foo one	1.075770	-0.109050	1.643563	-1.469388
two	0.357021	-0.674600	-1.776904	-0.968914
qux one	-1.294524	0.413738	0.276662	-0.472035
two	-0.013960	-0.362543	-0.006154	-0.923061

All of the MultiIndex constructors accept a `names` argument which stores string names for the levels themselves. If no names are provided, `None` will be assigned:

In [17]: df.index.names

Out[17]: FrozenList([None, None])

This index can back any axis of a pandas object, and the number of `levels` of the index is up to you:

In [18]: df = pd.DataFrame(np.random.randn(3, 8), index=["A", "B", "C"], columns=index)

In [19]: df

Out[19]:

first	bar	baz	foo	qux				
second	one	two	one	two	one	two		
A	0.895717	0.805244	-1.206412	2.565646	1.431256	1.340309	-1.170299	-0.226169
B	0.410835	0.813850	0.132003	-0.827317	-0.076467	-1.187678	1.130127	-1.436737
C	-1.413681	1.607920	1.024180	0.569605	0.875906	-2.211372	0.974466	-2.006747

In [20]: pd.DataFrame(np.random.randn(6, 6), index=index[:6], columns=index[:6])

Out[20]:

first	bar	baz	foo				
second	one	two	one	two			
first	second						
bar	one	-0.410001	-0.078638	0.545952	-1.219217	-1.226825	0.769804
	two	-1.281247	-0.727707	-0.121306	-0.097883	0.695775	0.341734
baz	one	0.959726	-1.110336	-0.619976	0.149748	-0.732339	0.687738
	two	0.176444	0.403310	-0.154951	0.301624	-2.179861	-1.369849
foo	one	-0.954208	1.462696	-1.743161	-0.826591	-0.345352	1.314232
	two	0.690579	0.995761	2.396780	0.014871	3.357427	-0.317441

We've "sparsified" the higher levels of the indexes to make the console output a bit easier on the eyes. Note that how

the index is displayed can be controlled using the `multi_sparse` option in `pandas.set_options()`:

```
In [21]: with pd.option_context("display.multi_sparse", False):
....:     df
....:
```

It's worth keeping in mind that there's nothing preventing you from using tuples as atomic labels on an axis:

```
In [22]: pd.Series(np.random.randn(8), index=tuples)
Out[22]:
(bar, one)    -1.236269
(bar, two)     0.896171
(baz, one)    -0.487602
(baz, two)    -0.082240
(foo, one)    -2.182937
(foo, two)     0.380396
(qux, one)     0.084844
(qux, two)     0.432390
dtype: float64
```

The reason that the `MultiIndex` matters is that it can allow you to do grouping, selection, and reshaping operations as we will describe below and in subsequent areas of the documentation. As you will see in later sections, you can find yourself working with hierarchically-indexed data without creating a `MultiIndex` explicitly yourself. However, when loading data from a file, you may wish to generate your own `MultiIndex` when preparing the data set.

Reconstructing the level labels

The method `get_level_values()` will return a vector of the labels for each location at a particular level:

```
In [23]: index.get_level_values(0)
Out[23]: Index(['bar', 'bar', 'baz', 'baz', 'foo', 'foo', 'qux', 'qux'], dtype='object', name='first')

In [24]: index.get_level_values("second")
Out[24]: Index(['one', 'two', 'one', 'two', 'one', 'two', 'one', 'two'], dtype='object', name='second')
```

Basic indexing on axis with MultiIndex

One of the important features of hierarchical indexing is that you can select data by a “partial” label identifying a subgroup in the data. **Partial** selection “drops” levels of the hierarchical index in the result in a completely analogous way to selecting a column in a regular DataFrame:

```
In [25]: df["bar"]
Out[25]:
second      one      two
A        0.895717  0.805244
B        0.410835  0.813850
C       -1.413681  1.607920

In [26]: df["bar", "one"]
Out[26]:
```

(continues on next page)

(continued from previous page)

```
A    0.895717
B    0.410835
C   -1.413681
Name: (bar, one), dtype: float64
```

In [27]: df["bar"]["one"]

Out[27]:

```
A    0.895717
B    0.410835
C   -1.413681
Name: one, dtype: float64
```

In [28]: s["qux"]

Out[28]:

```
one   -1.039575
two    0.271860
dtype: float64
```

See [Cross-section with hierarchical index](#) for how to select on a deeper level.

Defined levels

The `MultiIndex` keeps all the defined levels of an index, even if they are not actually used. When slicing an index, you may notice this. For example:

In [29]: df.columns.levels # original MultiIndex

Out[29]: FrozenList([['bar', 'baz', 'foo', 'qux'], ['one', 'two']])

In [30]: df[["foo", "qux"]].columns.levels # sliced

Out[30]: FrozenList([['bar', 'baz', 'foo', 'qux'], ['one', 'two']])

This is done to avoid a recomputation of the levels in order to make slicing highly performant. If you want to see only the used levels, you can use the `get_level_values()` method.

In [31]: df[["foo", "qux"]].columns.to_numpy()

Out[31]:

```
array([('foo', 'one'), ('foo', 'two'), ('qux', 'one'), ('qux', 'two')],  
      dtype=object)
```

for a specific level

In [32]: df[["foo", "qux"]].columns.get_level_values(0)

Out[32]: Index(['foo', 'foo', 'qux', 'qux'], dtype='object', name='first')

To reconstruct the `MultiIndex` with only the used levels, the `remove_unused_levels()` method may be used.

In [33]: new_mi = df[["foo", "qux"]].columns.remove_unused_levels()

In [34]: new_mi.levels

Out[34]: FrozenList([['foo', 'qux'], ['one', 'two']])

Data alignment and using reindex

Operations between differently-indexed objects having MultiIndex on the axes will work as you expect; data alignment will work the same as an Index of tuples:

```
In [35]: s + s[:-2]
```

```
Out[35]:
```

```
bar one -1.723698
      two -4.209138
baz one -0.989859
      two 2.143608
foo one 1.443110
      two -1.413542
qux one      NaN
      two      NaN
dtype: float64
```

```
In [36]: s + s[::-2]
```

```
Out[36]:
```

```
bar one -1.723698
      two      NaN
baz one -0.989859
      two      NaN
foo one 1.443110
      two      NaN
qux one -2.079150
      two      NaN
dtype: float64
```

The `reindex()` method of Series/DataFrames can be called with another MultiIndex, or even a list or array of tuples:

```
In [37]: s.reindex(index[:3])
```

```
Out[37]:
```

```
first second
bar one -0.861849
      two -2.104569
baz one -0.494929
dtype: float64
```

```
In [38]: s.reindex([("foo", "two"), ("bar", "one"), ("qux", "one"), ("baz", "one")])
```

```
Out[38]:
```

```
foo two -0.706771
bar one -0.861849
qux one -1.039575
baz one -0.494929
dtype: float64
```

2.6.2 Advanced indexing with hierarchical index

Syntactically integrating MultiIndex in advanced indexing with .loc is a bit challenging, but we've made every effort to do so. In general, MultiIndex keys take the form of tuples. For example, the following works as you would expect:

```
In [39]: df = df.T
```

```
In [40]: df
```

```
Out[40]:
```

		A	B	C
first	second			
bar	one	0.895717	0.410835	-1.413681
	two	0.805244	0.813850	1.607920
baz	one	-1.206412	0.132003	1.024180
	two	2.565646	-0.827317	0.569605
foo	one	1.431256	-0.076467	0.875906
	two	1.340309	-1.187678	-2.211372
qux	one	-1.170299	1.130127	0.974466
	two	-0.226169	-1.436737	-2.006747

```
In [41]: df.loc[("bar", "two")]
```

```
Out[41]:
```

		A	B	C
		0.805244		
		0.813850		
		1.607920		
	Name:	(bar, two)		
				dtype: float64

Note that df.loc['bar', 'two'] would also work in this example, but this shorthand notation can lead to ambiguity in general.

If you also want to index a specific column with .loc, you must use a tuple like this:

```
In [42]: df.loc[("bar", "two"), "A"]
```

```
Out[42]: 0.8052440253863785
```

You don't have to specify all levels of the MultiIndex by passing only the first elements of the tuple. For example, you can use “partial” indexing to get all elements with bar in the first level as follows:

```
In [43]: df.loc["bar"]
```

```
Out[43]:
```

		A	B	C
second				
one		0.895717	0.410835	-1.413681
two		0.805244	0.813850	1.607920

This is a shortcut for the slightly more verbose notation df.loc[('bar',),] (equivalent to df.loc['bar',] in this example).

“Partial” slicing also works quite nicely.

```
In [44]: df.loc["baz":"foo"]
```

```
Out[44]:
```

		A	B	C
first	second			
baz	one	-1.206412	0.132003	1.024180

(continues on next page)

(continued from previous page)

	two	2.565646	-0.827317	0.569605
foo	one	1.431256	-0.076467	0.875906
	two	1.340309	-1.187678	-2.211372

You can slice with a ‘range’ of values, by providing a slice of tuples.

```
In [45]: df.loc[("baz", "two"):(("qux", "one"))]
Out[45]:
```

	A	B	C	
first	second			
baz	two	2.565646	-0.827317	0.569605
foo	one	1.431256	-0.076467	0.875906
	two	1.340309	-1.187678	-2.211372
qux	one	-1.170299	1.130127	0.974466

```
In [46]: df.loc[("baz", "two"):"foo"]
```

```
Out[46]:
```

	A	B	C	
first	second			
baz	two	2.565646	-0.827317	0.569605
foo	one	1.431256	-0.076467	0.875906
	two	1.340309	-1.187678	-2.211372

Passing a list of labels or tuples works similar to reindexing:

```
In [47]: df.loc[[("bar", "two"), ("qux", "one"))]
Out[47]:
```

	A	B	C	
first	second			
bar	two	0.805244	0.813850	1.607920
qux	one	-1.170299	1.130127	0.974466

Note: It is important to note that tuples and lists are not treated identically in pandas when it comes to indexing. Whereas a tuple is interpreted as one multi-level key, a list is used to specify several keys. Or in other words, tuples go horizontally (traversing levels), lists go vertically (scanning levels).

Importantly, a list of tuples indexes several complete MultiIndex keys, whereas a tuple of lists refer to several values within a level:

```
In [48]: s = pd.Series(
    ....:     [1, 2, 3, 4, 5, 6],
    ....:     index=pd.MultiIndex.from_product([["A", "B"], ["c", "d", "e"]]),
    ....: )
    ....:
```

```
In [49]: s.loc[[("A", "c"), ("B", "d")]] # list of tuples
```

```
Out[49]:
```

A	c	1
B	d	5
		dtype: int64

(continues on next page)

(continued from previous page)

```
In [50]: s.loc[[["A", "B"], ["c", "d"]]] # tuple of lists
Out[50]:
A  c    1
   d    2
B  c    4
   d    5
dtype: int64
```

Using slicers

You can slice a MultiIndex by providing multiple indexers.

You can provide any of the selectors as if you are indexing by label, see [Selection by Label](#), including slices, lists of labels, labels, and boolean indexers.

You can use `slice(None)` to select all the contents of *that* level. You do not need to specify all the *deeper* levels, they will be implied as `slice(None)`.

As usual, **both sides** of the slicers are included as this is label indexing.

Warning: You should specify all axes in the `.loc` specifier, meaning the indexer for the **index** and for the **columns**. There are some ambiguous cases where the passed indexer could be mis-interpreted as indexing *both* axes, rather than into say the MultiIndex for the rows.

You should do this:

```
df.loc[[slice("A1", "A3"), ...], :] # noqa: E999
```

You should **not** do this:

```
df.loc[[slice("A1", "A3"), ...]] # noqa: E999
```

```
In [51]: def mklbl(prefix, n):
....:     return ["%s%s" % (prefix, i) for i in range(n)]
....:

In [52]: miindex = pd.MultiIndex.from_product(
....:         [mklbl("A", 4), mklbl("B", 2), mklbl("C", 4), mklbl("D", 2)])
....:
....:

In [53]: micolumns = pd.MultiIndex.from_tuples(
....:         [("a", "foo"), ("a", "bar"), ("b", "foo"), ("b", "bah")], names=["lvl0",
....: "lvl1"])
....:
....:

In [54]: dfmi = (
....:     pd.DataFrame(
....:         np.arange(len(miindex) * len(micolumns)).reshape(
....:             (len(miindex), len(micolumns))
....:         ),
```

(continues on next page)

(continued from previous page)

```

....:
        index=miindex,
        columns=micolumns,
    )
....:
    .sort_index()
....:
    .sort_index(axis=1)
....:
)
....:

```

In [55]: dfmi**Out[55]:**

	lv10	a	b					
	lv11	bar	foo	bah	foo			
A0	B0	C0	D0	1	0	3	2	
			D1	5	4	7	6	
		C1	D0	9	8	11	10	
			D1	13	12	15	14	
		C2	D0	17	16	19	18	
		
A3	B1	C1	D1	237	236	239	238	
			C2	D0	241	240	243	242
				D1	245	244	247	246
		C3	D0	249	248	251	250	
			D1	253	252	255	254	

[64 rows x 4 columns]

Basic MultiIndex slicing using slices, lists, and labels.

In [56]: dfmi.loc[(slice("A1", "A3"), slice(None), ["C1", "C3"]), :]**Out[56]:**

	lv10	a	b				
	lv11	bar	foo	bah	foo		
A1	B0	C1	D0	73	72	75	74
			D1	77	76	79	78
		C3	D0	89	88	91	90
			D1	93	92	95	94
	B1	C1	D0	105	104	107	106

A3	B0	C3	D1	221	220	223	222
	B1	C1	D0	233	232	235	234
			D1	237	236	239	238
	C3	D0	249	248	251	250	
		D1	253	252	255	254	

[24 rows x 4 columns]

You can use `pandas.IndexSlice` to facilitate a more natural syntax using `:`, rather than using `slice(None)`.**In [57]:** idx = pd.IndexSlice**In [58]:** dfmi.loc[idx[:, :, ["C1", "C3"]], idx[:, "foo"]]**Out[58]:**

(continues on next page)

(continued from previous page)

```

lvl0      a    b
lvl1      foo   foo
A0 B0 C1 D0    8   10
              D1   12   14
              C3 D0   24   26
              D1   28   30
B1 C1 D0   40   42
...
A3 B0 C3 D1  220  222
B1 C1 D0   232  234
              D1   236  238
C3 D0   248  250
              D1   252  254

```

[32 rows x 2 columns]

It is possible to perform quite complicated selections using this method on multiple axes at the same time.

In [59]: dfmi.loc["A1", (slice(None), "foo")]

Out[59]:

```

lvl0      a    b
lvl1      foo   foo
B0 C0 D0   64   66
              D1   68   70
              C1 D0   72   74
              D1   76   78
C2 D0   80   82
...
B1 C1 D1  108  110
C2 D0   112  114
              D1   116  118
C3 D0   120  122
              D1   124  126

```

[16 rows x 2 columns]

In [60]: dfmi.loc[idx[:, :, ["C1", "C3"]], idx[:, "foo"]]

Out[60]:

```

lvl0      a    b
lvl1      foo   foo
A0 B0 C1 D0    8   10
              D1   12   14
              C3 D0   24   26
              D1   28   30
B1 C1 D0   40   42
...
A3 B0 C3 D1  220  222
B1 C1 D0   232  234
              D1   236  238
C3 D0   248  250
              D1   252  254

```

(continues on next page)

(continued from previous page)

[32 rows x 2 columns]

Using a boolean indexer you can provide selection related to the *values*.

In [61]: mask = dfmi[("a", "foo")] > 200																											
In [62]: dfmi.loc[idx[mask, :, ["C1", "C3"]], idx[:, "foo"]]																											
Out[62]:																											
<table border="1"> <tr><td>lvl0</td><td>a</td><td>b</td></tr> <tr><td>lvl1</td><td>foo</td><td>foo</td></tr> <tr><td>A3 B0 C1 D1</td><td>204</td><td>206</td></tr> <tr><td> C3 D0</td><td>216</td><td>218</td></tr> <tr><td> D1</td><td>220</td><td>222</td></tr> <tr><td>B1 C1 D0</td><td>232</td><td>234</td></tr> <tr><td> D1</td><td>236</td><td>238</td></tr> <tr><td>C3 D0</td><td>248</td><td>250</td></tr> <tr><td> D1</td><td>252</td><td>254</td></tr> </table>	lvl0	a	b	lvl1	foo	foo	A3 B0 C1 D1	204	206	C3 D0	216	218	D1	220	222	B1 C1 D0	232	234	D1	236	238	C3 D0	248	250	D1	252	254
lvl0	a	b																									
lvl1	foo	foo																									
A3 B0 C1 D1	204	206																									
C3 D0	216	218																									
D1	220	222																									
B1 C1 D0	232	234																									
D1	236	238																									
C3 D0	248	250																									
D1	252	254																									

You can also specify the `axis` argument to `.loc` to interpret the passed slicers on a single axis.

In [63]: dfmi.loc(axis=0)[:, :, ["C1", "C3"]]																																																															
Out[63]:																																																															
<table border="1"> <tr><td>lvl0</td><td>a</td><td>b</td></tr> <tr><td>lvl1</td><td>bar</td><td>foo</td><td>bah</td><td>foo</td></tr> <tr><td>A0 B0 C1 D0</td><td>9</td><td>8</td><td>11</td><td>10</td></tr> <tr><td> D1</td><td>13</td><td>12</td><td>15</td><td>14</td></tr> <tr><td> C3 D0</td><td>25</td><td>24</td><td>27</td><td>26</td></tr> <tr><td> D1</td><td>29</td><td>28</td><td>31</td><td>30</td></tr> <tr><td>B1 C1 D0</td><td>41</td><td>40</td><td>43</td><td>42</td></tr> <tr><td>...</td><td>...</td><td>...</td><td>...</td><td>...</td></tr> <tr><td>A3 B0 C3 D1</td><td>221</td><td>220</td><td>223</td><td>222</td></tr> <tr><td> B1 C1 D0</td><td>233</td><td>232</td><td>235</td><td>234</td></tr> <tr><td> D1</td><td>237</td><td>236</td><td>239</td><td>238</td></tr> <tr><td> C3 D0</td><td>249</td><td>248</td><td>251</td><td>250</td></tr> <tr><td> D1</td><td>253</td><td>252</td><td>255</td><td>254</td></tr> </table>	lvl0	a	b	lvl1	bar	foo	bah	foo	A0 B0 C1 D0	9	8	11	10	D1	13	12	15	14	C3 D0	25	24	27	26	D1	29	28	31	30	B1 C1 D0	41	40	43	42	A3 B0 C3 D1	221	220	223	222	B1 C1 D0	233	232	235	234	D1	237	236	239	238	C3 D0	249	248	251	250	D1	253	252	255	254
lvl0	a	b																																																													
lvl1	bar	foo	bah	foo																																																											
A0 B0 C1 D0	9	8	11	10																																																											
D1	13	12	15	14

qux	-1.170299	1.130127	0.974466

using the slicers

In [72]: df.loc[:, slice(None), "one", :]**Out[72]:**

	A	B	C
first second			
bar one	0.895717	0.410835	-1.413681
baz one	-1.206412	0.132003	1.024180
foo one	1.431256	-0.076467	0.875906
qux one	-1.170299	1.130127	0.974466

You can also select on the columns with `xs`, by providing the `axis` argument.**In [73]:** df = df.T**In [74]:** df.xs("one", level="second", axis=1)**Out[74]:**

	bar	baz	foo	qux
A	0.895717	-1.206412	1.431256	-1.170299
B	0.410835	0.132003	-0.076467	1.130127
C	-1.413681	1.024180	0.875906	0.974466

using the slicers

In [75]: df.loc[:, :, slice(None), "one"]**Out[75]:**

	bar	baz	foo	qux
first	bar	baz	foo	qux
second	one	one	one	one
A	0.895717	-1.206412	1.431256	-1.170299
B	0.410835	0.132003	-0.076467	1.130127
C	-1.413681	1.024180	0.875906	0.974466

`xs` also allows selection with multiple keys.**In [76]:** df.xs(("one", "bar"), level=("second", "first"), axis=1)**Out[76]:**

	bar
first	bar
second	one
A	0.895717
B	0.410835
C	-1.413681

using the slicers

In [77]: df.loc[:, :, ("bar", "one")]**Out[77]:**

(continues on next page)

(continued from previous page)

```
A    0.895717
B    0.410835
C   -1.413681
Name: (bar, one), dtype: float64
```

You can pass `drop_level=False` to `xs` to retain the level that was selected.

```
In [78]: df.xs("one", level="second", axis=1, drop_level=False)
Out[78]:
first      bar      baz      foo      qux
second     one      one      one      one
A         0.895717 -1.206412  1.431256 -1.170299
B         0.410835  0.132003 -0.076467  1.130127
C        -1.413681  1.024180  0.875906  0.974466
```

Compare the above with the result using `drop_level=True` (the default value).

```
In [79]: df.xs("one", level="second", axis=1, drop_level=True)
Out[79]:
first      bar      baz      foo      qux
A         0.895717 -1.206412  1.431256 -1.170299
B         0.410835  0.132003 -0.076467  1.130127
C        -1.413681  1.024180  0.875906  0.974466
```

Advanced reindexing and alignment

Using the parameter `level` in the `reindex()` and `align()` methods of pandas objects is useful to broadcast values across a level. For instance:

```
In [80]: midx = pd.MultiIndex(
.....:     levels=[["zero", "one"], ["x", "y"]], codes=[[1, 1, 0, 0], [1, 0, 1, 0]]
.....: )
.....:

In [81]: df = pd.DataFrame(np.random.randn(4, 2), index=midx)

In [82]: df
Out[82]:
          0           1
one  y  1.519970 -0.493662
      x  0.600178  0.274230
zero y  0.132885 -0.023688
      x  2.410179  1.450520

In [83]: df2 = df.groupby(level=0).mean()

In [84]: df2
Out[84]:
          0           1
one    1.060074 -0.109716
zero   1.271532  0.713416
```

(continues on next page)

(continued from previous page)

```
In [85]: df2.reindex(df.index, level=0)
Out[85]:
      0      1
one  y  1.060074 -0.109716
     x  1.060074 -0.109716
zero y  1.271532  0.713416
     x  1.271532  0.713416

# aligning
In [86]: df_aligned, df2_aligned = df.align(df2, level=0)

In [87]: df_aligned
Out[87]:
      0      1
one  y  1.519970 -0.493662
     x  0.600178  0.274230
zero y  0.132885 -0.023688
     x  2.410179  1.450520

In [88]: df2_aligned
Out[88]:
      0      1
one  y  1.060074 -0.109716
     x  1.060074 -0.109716
zero y  1.271532  0.713416
     x  1.271532  0.713416
```

Swapping levels with `swaplevel`

The `swaplevel()` method can switch the order of two levels:

```
In [89]: df[:5]
Out[89]:
      0      1
one  y  1.519970 -0.493662
     x  0.600178  0.274230
zero y  0.132885 -0.023688
     x  2.410179  1.450520

In [90]: df[:5].swaplevel(0, 1, axis=0)
Out[90]:
      0      1
y one  1.519970 -0.493662
x one  0.600178  0.274230
y zero 0.132885 -0.023688
x zero 2.410179  1.450520
```

Reordering levels with `reorder_levels`

The `reorder_levels()` method generalizes the `swaplevel` method, allowing you to permute the hierarchical index levels in one step:

```
In [91]: df[:5].reorder_levels([1, 0], axis=0)
Out[91]:
          0      1
y one  1.519970 -0.493662
x one  0.600178  0.274230
y zero 0.132885 -0.023688
x zero 2.410179  1.450520
```

Renaming names of an Index or MultiIndex

The `rename()` method is used to rename the labels of a MultiIndex, and is typically used to rename the columns of a DataFrame. The `columns` argument of `rename` allows a dictionary to be specified that includes only the columns you wish to rename.

```
In [92]: df.rename(columns={0: "col0", 1: "col1"})
Out[92]:
      col0      col1
one  y  1.519970 -0.493662
     x  0.600178  0.274230
zero y  0.132885 -0.023688
     x  2.410179  1.450520
```

This method can also be used to rename specific labels of the main index of the DataFrame.

```
In [93]: df.rename(index={"one": "two", "y": "z"})
Out[93]:
          0      1
two  z  1.519970 -0.493662
     x  0.600178  0.274230
zero z  0.132885 -0.023688
     x  2.410179  1.450520
```

The `rename_axis()` method is used to rename the name of a Index or MultiIndex. In particular, the names of the levels of a MultiIndex can be specified, which is useful if `reset_index()` is later used to move the values from the MultiIndex to a column.

```
In [94]: df.rename_axis(index=["abc", "def"])
Out[94]:
      0      1
abc def
one  y  1.519970 -0.493662
     x  0.600178  0.274230
zero y  0.132885 -0.023688
     x  2.410179  1.450520
```

Note that the columns of a DataFrame are an index, so that using `rename_axis` with the `columns` argument will change the name of that index.

```
In [95]: df.rename_axis(columns="Cols").columns
Out[95]: RangeIndex(start=0, stop=2, step=1, name='Cols')
```

Both `rename` and `rename_axis` support specifying a dictionary, `Series` or a mapping function to map labels/names to new values.

When working with an `Index` object directly, rather than via a `DataFrame`, `Index.set_names()` can be used to change the names.

```
In [96]: mi = pd.MultiIndex.from_product([[1, 2], ["a", "b"]], names=["x", "y"])

In [97]: mi.names
Out[97]: FrozenList(['x', 'y'])

In [98]: mi2 = mi.rename("new name", level=0)

In [99]: mi2
Out[99]:
MultiIndex([(1, 'a'),
             (1, 'b'),
             (2, 'a'),
             (2, 'b')], names=['new name', 'y'])
```

You cannot set the names of the MultiIndex via a level.

```
In [100]: mi.levels[0].name = "name via level"
-----
RuntimeError                                     Traceback (most recent call last)
Input In [100], in <module>
----> 1 mi.levels[0].name = "name via level"

1660         # Used in MultiIndex.levels to avoid silently ignoring name updates.
-> 1661     raise RuntimeError(
1662         "Cannot set name on a level of a MultiIndex. Use "
1663         "'MultiIndex.set_names' instead."
1664     )
1665     maybe_extract_name(value, None, type(self))
1666     self._name = value

RuntimeError: Cannot set name on a level of a MultiIndex. Use 'MultiIndex.set_names' instead.
```

Use `Index.set_names()` instead.

2.6.3 Sorting a MultiIndex

For *MultiIndex*-ed objects to be indexed and sliced effectively, they need to be sorted. As with any index, you can use `sort_index()`.

```
In [101]: import random

In [102]: random.shuffle(tuples)

In [103]: s = pd.Series(np.random.randn(8), index=pd.MultiIndex.from_tuples(tuples))

In [104]: s
Out[104]:
baz  two    0.206053
qux  two   -0.251905
foo  one   -2.213588
bar  one    1.063327
qux  one    1.266143
baz  one    0.299368
bar  two   -0.863838
foo  two    0.408204
dtype: float64

In [105]: s.sort_index()
Out[105]:
bar  one    1.063327
      two   -0.863838
baz  one    0.299368
      two    0.206053
foo  one   -2.213588
      two    0.408204
qux  one    1.266143
      two   -0.251905
dtype: float64

In [106]: s.sort_index(level=0)
Out[106]:
bar  one    1.063327
      two   -0.863838
baz  one    0.299368
      two    0.206053
foo  one   -2.213588
      two    0.408204
qux  one    1.266143
      two   -0.251905
dtype: float64

In [107]: s.sort_index(level=1)
Out[107]:
bar  one    1.063327
baz  one    0.299368
foo  one   -2.213588
qux  one    1.266143
```

(continues on next page)

(continued from previous page)

```
bar  two    -0.863838
baz  two     0.206053
foo  two     0.408204
qux  two    -0.251905
dtype: float64
```

You may also pass a level name to `sort_index` if the `MultiIndex` levels are named.

In [108]: `s.index.set_names(["L1", "L2"], inplace=True)`

In [109]: `s.sort_index(level="L1")`

Out[109]:

```
L1   L2
bar  one    1.063327
      two    -0.863838
baz  one    0.299368
      two    0.206053
foo  one    -2.213588
      two     0.408204
qux  one    1.266143
      two    -0.251905
dtype: float64
```

In [110]: `s.sort_index(level="L2")`

Out[110]:

```
L1   L2
bar  one    1.063327
baz  one    0.299368
foo  one    -2.213588
qux  one    1.266143
bar  two    -0.863838
baz  two    0.206053
foo  two     0.408204
qux  two    -0.251905
dtype: float64
```

On higher dimensional objects, you can sort any of the other axes by level if they have a `MultiIndex`:

In [111]: `df.T.sort_index(level=1, axis=1)`

Out[111]:

	one	zero	one	zero
	x	x	y	y
0	0.600178	2.410179	1.519970	0.132885
1	0.274230	1.450520	-0.493662	-0.023688

Indexing will work even if the data are not sorted, but will be rather inefficient (and show a `PerformanceWarning`). It will also return a copy of the data rather than a view:

In [112]: `dfm = pd.DataFrame(
.....: {"jim": [0, 0, 1, 1], "joe": ["x", "x", "z", "y"], "jolie": np.random.
.....: rand(4)}
.....:)
.....:`

(continues on next page)

(continued from previous page)

```
In [113]: dfm = dfm.set_index(["jim", "joe"])
```

```
In [114]: dfm
```

```
Out[114]:
          jolie
jim joe
0    x    0.490671
     x    0.120248
1    z    0.537020
     y    0.110968
```

```
In [4]: dfm.loc[(1, 'z')]
```

PerformanceWarning: indexing past lexsort depth may impact performance.

```
Out[4]:
          jolie
```

```
jim joe
1    z    0.64094
```

Furthermore, if you try to index something that is not fully lexsorted, this can raise:

```
In [5]: dfm.loc[(0, 'y'): (1, 'z')]
```

UnsortedIndexError: 'Key length (2) was greater than MultiIndex lexsort depth (1)'

The `is_monotonic_increasing()` method on a `MultiIndex` shows if the index is sorted:

```
In [115]: dfm.index.is_monotonic_increasing
```

```
Out[115]: False
```

```
In [116]: dfm = dfm.sort_index()
```

```
In [117]: dfm
```

```
Out[117]:
          jolie
jim joe
0    x    0.490671
     x    0.120248
1    y    0.110968
     z    0.537020
```

```
In [118]: dfm.index.is_monotonic_increasing
```

```
Out[118]: True
```

And now selection works as expected.

```
In [119]: dfm.loc[(0, "y") : (1, "z")]
```

```
Out[119]:
          jolie
jim joe
1    y    0.110968
     z    0.537020
```

2.6.4 Take methods

Similar to NumPy ndarrays, pandas Index, Series, and DataFrame also provides the `take()` method that retrieves elements along a given axis at the given indices. The given indices must be either a list or an ndarray of integer index positions. `take` will also accept negative integers as relative positions to the end of the object.

```
In [120]: index = pd.Index(np.random.randint(0, 1000, 10))

In [121]: index
Out[121]: Int64Index([214, 502, 712, 567, 786, 175, 993, 133, 758, 329], dtype='int64')

In [122]: positions = [0, 9, 3]

In [123]: index[positions]
Out[123]: Int64Index([214, 329, 567], dtype='int64')

In [124]: index.take(positions)
Out[124]: Int64Index([214, 329, 567], dtype='int64')

In [125]: ser = pd.Series(np.random.randn(10))

In [126]: ser.iloc[positions]
Out[126]:
0    -0.179666
9     1.824375
3     0.392149
dtype: float64

In [127]: ser.take(positions)
Out[127]:
0    -0.179666
9     1.824375
3     0.392149
dtype: float64
```

For DataFrames, the given indices should be a 1d list or ndarray that specifies row or column positions.

```
In [128]: frm = pd.DataFrame(np.random.randn(5, 3))

In [129]: frm.take([1, 4, 3])
Out[129]:
      0         1         2
1 -1.237881  0.106854 -1.276829
4  0.629675 -1.425966  1.857704
3  0.979542 -1.633678  0.615855

In [130]: frm.take([0, 2], axis=1)
Out[130]:
      0         2
0  0.595974  0.601544
1 -1.237881 -1.276829
2 -0.767101  1.499591
3  0.979542  0.615855
4  0.629675  1.857704
```

It is important to note that the `take` method on pandas objects are not intended to work on boolean indices and may return unexpected results.

```
In [131]: arr = np.random.randn(10)

In [132]: arr.take([False, False, True, True])
Out[132]: array([-1.1935, -1.1935,  0.6775,  0.6775])

In [133]: arr[[0, 1]]
Out[133]: array([-1.1935,  0.6775])

In [134]: ser = pd.Series(np.random.randn(10))

In [135]: ser.take([False, False, True, True])
Out[135]:
0    0.233141
0    0.233141
1   -0.223540
1   -0.223540
dtype: float64

In [136]: ser.iloc[[0, 1]]
Out[136]:
0    0.233141
1   -0.223540
dtype: float64
```

Finally, as a small note on performance, because the `take` method handles a narrower range of inputs, it can offer performance that is a good deal faster than fancy indexing.

```
In [137]: arr = np.random.randn(10000, 5)

In [138]: indexer = np.arange(10000)

In [139]: random.shuffle(indexer)

In [140]: %timeit arr[indexer]
.....: %timeit arr.take(indexer, axis=0)
.....:
210 us +- 12.5 us per loop (mean +- std. dev. of 7 runs, 1,000 loops each)
63.6 us +- 6.41 us per loop (mean +- std. dev. of 7 runs, 10,000 loops each)
```

```
In [141]: ser = pd.Series(arr[:, 0])

In [142]: %timeit ser.iloc[indexer]
.....: %timeit ser.take(indexer)
.....:
99.2 us +- 9.69 us per loop (mean +- std. dev. of 7 runs, 10,000 loops each)
92.6 us +- 6.58 us per loop (mean +- std. dev. of 7 runs, 10,000 loops each)
```

2.6.5 Index types

We have discussed MultiIndex in the previous sections pretty extensively. Documentation about DatetimeIndex and PeriodIndex are shown [here](#), and documentation about TimedeltaIndex is found [here](#).

In the following sub-sections we will highlight some other index types.

CategoricalIndex

`CategoricalIndex` is a type of index that is useful for supporting indexing with duplicates. This is a container around a `Categorical` and allows efficient indexing and storage of an index with a large number of duplicated elements.

```
In [143]: from pandas.api.types import CategoricalDtype
In [144]: df = pd.DataFrame({"A": np.arange(6), "B": list("aabbca")})
In [145]: df["B"] = df["B"].astype(CategoricalDtype(list("cab")))
In [146]: df
Out[146]:
   A    B
0  0    a
1  1    a
2  2    b
3  3    b
4  4    c
5  5    a

In [147]: df.dtypes
Out[147]:
A      int64
B    category
dtype: object

In [148]: df["B"].cat.categories
Out[148]: Index(['c', 'a', 'b'], dtype='object')
```

Setting the index will create a `CategoricalIndex`.

```
In [149]: df2 = df.set_index("B")
In [150]: df2.index
Out[150]: CategoricalIndex(['a', 'a', 'b', 'b', 'c', 'a'], categories=['c', 'a', 'b'],
                           ordered=False, dtype='category', name='B')
```

Indexing with `__getitem__`/`.iloc`/`.loc` works similarly to an `Index` with duplicates. The indexers **must** be in the category or the operation will raise a `KeyError`.

```
In [151]: df2.loc["a"]
Out[151]:
   A
B
a  0
```

(continues on next page)

(continued from previous page)

```
a 1
a 5
```

The CategoricalIndex is **preserved** after indexing:

```
In [152]: df2.loc["a"].index
Out[152]: CategoricalIndex(['a', 'a', 'a'], categories=['c', 'a', 'b'], ordered=False, 
                           dtype='category', name='B')
```

Sorting the index will sort by the order of the categories (recall that we created the index with CategoricalDtype(list('cab'))), so the sorted order is cab).

```
In [153]: df2.sort_index()
Out[153]:
A
B
c 4
a 0
a 1
a 5
b 2
b 3
```

Groupby operations on the index will preserve the index nature as well.

```
In [154]: df2.groupby(level=0).sum()
Out[154]:
A
B
c 4
a 6
b 5

In [155]: df2.groupby(level=0).sum().index
Out[155]: CategoricalIndex(['c', 'a', 'b'], categories=['c', 'a', 'b'], ordered=False, 
                           dtype='category', name='B')
```

Reindexing operations will return a resulting index based on the type of the passed indexer. Passing a list will return a plain-old Index; indexing with a Categorical will return a CategoricalIndex, indexed according to the categories of the **passed** Categorical dtype. This allows one to arbitrarily index these even with values **not** in the categories, similarly to how you can reindex **any** pandas index.

```
In [156]: df3 = pd.DataFrame(
.....:     {"A": np.arange(3), "B": pd.Series(list("abc")).astype("category")}
.....: )
.....:

In [157]: df3 = df3.set_index("B")

In [158]: df3
Out[158]:
A
B
```

(continues on next page)

(continued from previous page)

```
a  0
b  1
c  2
```

In [159]: df3.reindex(["a", "e"])

Out[159]:

```
A
B
a  0.0
e  NaN
```

In [160]: df3.reindex(["a", "e"]).index

Out[160]: Index(['a', 'e'], dtype='object', name='B')

In [161]: df3.reindex(pd.Categorical(["a", "e"], categories=list("abe")))

Out[161]:

```
A
B
a  0.0
e  NaN
```

In [162]: df3.reindex(pd.Categorical(["a", "e"], categories=list("abe"))).index

Out[162]: CategoricalIndex(['a', 'e'], categories=['a', 'b', 'e'], ordered=False, dtype='category', name='B')

Warning: Reshaping and Comparison operations on a CategoricalIndex must have the same categories or a TypeError will be raised.

In [163]: df4 = pd.DataFrame({"A": np.arange(2), "B": list("ba")})

In [164]: df4["B"] = df4["B"].astype(CategoricalDtype(list("ab")))

In [165]: df4 = df4.set_index("B")

In [166]: df4.index

Out[166]: CategoricalIndex(['b', 'a'], categories=['a', 'b'], ordered=False, dtype='category', name='B')

In [167]: df5 = pd.DataFrame({"A": np.arange(2), "B": list("bc")})

In [168]: df5["B"] = df5["B"].astype(CategoricalDtype(list("bc")))

In [169]: df5 = df5.set_index("B")

In [170]: df5.index

Out[170]: CategoricalIndex(['b', 'c'], categories=['b', 'c'], ordered=False, dtype='category', name='B')

In [1]: pd.concat([df4, df5])

TypeError: categories must match existing categories when appending

Int64Index and RangeIndex

Deprecated since version 1.4.0: In pandas 2.0, `Index` will become the default index type for numeric types instead of `Int64Index`, `Float64Index` and `UInt64Index` and those index types are therefore deprecated and will be removed in a future version. `RangeIndex` will not be removed, as it represents an optimized version of an integer index.

`Int64Index` is a fundamental basic index in pandas. This is an immutable array implementing an ordered, sliceable set.

`RangeIndex` is a sub-class of `Int64Index` that provides the default index for all `NDFrame` objects. `RangeIndex` is an optimized version of `Int64Index` that can represent a monotonic ordered set. These are analogous to Python `range` types.

Float64Index

Deprecated since version 1.4.0: `Index` will become the default index type for numeric types in the future instead of `Int64Index`, `Float64Index` and `UInt64Index` and those index types are therefore deprecated and will be removed in a future version of Pandas. `RangeIndex` will not be removed as it represents an optimized version of an integer index.

By default a `Float64Index` will be automatically created when passing floating, or mixed-integer-floating values in index creation. This enables a pure label-based slicing paradigm that makes `[]`, `ix`, `loc` for scalar indexing and slicing work exactly the same.

```
In [171]: indexf = pd.Index([1.5, 2, 3, 4.5, 5])
In [172]: indexf
Out[172]: Float64Index([1.5, 2.0, 3.0, 4.5, 5.0], dtype='float64')

In [173]: sf = pd.Series(range(5), index=indexf)

In [174]: sf
Out[174]:
1.5      0
2.0      1
3.0      2
4.5      3
5.0      4
dtype: int64
```

Scalar selection for `[]`, `.loc` will always be label based. An integer will match an equal float index (e.g. 3 is equivalent to `3.0`).

```
In [175]: sf[3]
Out[175]: 2

In [176]: sf[3.0]
Out[176]: 2

In [177]: sf.loc[3]
Out[177]: 2

In [178]: sf.loc[3.0]
Out[178]: 2
```

The only positional indexing is via `iloc`.

```
In [179]: sf.iloc[3]
Out[179]: 3
```

A scalar index that is not found will raise a `KeyError`. Slicing is primarily on the values of the index when using `[]`, `ix`, `loc`, and **always** positional when using `iloc`. The exception is when the slice is boolean, in which case it will always be positional.

```
In [180]: sf[2:4]
```

```
Out[180]:
```

```
2.0    1
3.0    2
dtype: int64
```

```
In [181]: sf.loc[2:4]
```

```
Out[181]:
```

```
2.0    1
3.0    2
dtype: int64
```

```
In [182]: sf.iloc[2:4]
```

```
Out[182]:
```

```
3.0    2
4.5    3
dtype: int64
```

In float indexes, slicing using floats is allowed.

```
In [183]: sf[2.1:4.6]
```

```
Out[183]:
```

```
3.0    2
4.5    3
dtype: int64
```

```
In [184]: sf.loc[2.1:4.6]
```

```
Out[184]:
```

```
3.0    2
4.5    3
dtype: int64
```

In non-float indexes, slicing using floats will raise a `TypeError`.

```
In [1]: pd.Series(range(5))[3.5]
```

```
TypeError: the label [3.5] is not a proper indexer for this index type (Int64Index)
```

```
In [1]: pd.Series(range(5))[3.5:4.5]
```

```
TypeError: the slice start [3.5] is not a proper indexer for this index type (Int64Index)
```

Here is a typical use-case for using this type of indexing. Imagine that you have a somewhat irregular timedelta-like indexing scheme, but the data is recorded as floats. This could, for example, be millisecond offsets.

```
In [185]: dfir = pd.concat(
.....:     [
```

(continues on next page)

(continued from previous page)

In [186]: dfir

In [185]:

	A	B
0.0	-0.435772	-1.188928
250.0	-0.808286	-0.284634
500.0	-1.815703	1.347213
750.0	-0.243487	0.514704
1000.0	1.162969	-0.287725
1000.4	-0.179734	0.993962
1250.5	-0.212673	0.909872
1500.6	-0.733333	-0.349893
1750.7	0.456434	-0.306735
2000.8	0.553396	0.166221
2250.9	-0.101684	-0.734907

Selection operations then will always work on a value basis, for all selection operators.

```
In [187]: dfir[0:1000.4]
```

Out[187]:

	A	B
0.0	-0.435772	-1.188928
250.0	-0.808286	-0.284634
500.0	-1.815703	1.347213
750.0	-0.243487	0.514704
1000.0	1.162969	-0.287725
1000.4	-0.179734	0.993962

```
In [188]: dfir.loc[0:1001, "A"]
```

Out[188]:

```
0.0      -0.435772
250.0    -0.808286
500.0    -1.815703
750.0    -0.243487
1000.0   1.162969
1000.4   -0.179734
Name: A, dtype: float64
```

```
In [189]: dfir.loc[1000:4]
```

Out[189]:

(continues on next page)

(continued from previous page)

```
A    -0.179734
B     0.993962
Name: 1000.4, dtype: float64
```

You could retrieve the first 1 second (1000 ms) of data as such:

```
In [190]: dfir[0:1000]
Out[190]:
      A          B
0.0   -0.435772 -1.188928
250.0  -0.808286 -0.284634
500.0  -1.815703  1.347213
750.0  -0.243487  0.514704
1000.0  1.162969 -0.287725
```

If you need integer based selection, you should use `iloc`:

```
In [191]: dfir.iloc[0:5]
Out[191]:
      A          B
0.0   -0.435772 -1.188928
250.0  -0.808286 -0.284634
500.0  -1.815703  1.347213
750.0  -0.243487  0.514704
1000.0  1.162969 -0.287725
```

IntervalIndex

`IntervalIndex` together with its own dtype, `IntervalDtype` as well as the `Interval` scalar type, allow first-class support in pandas for interval notation.

The `IntervalIndex` allows some unique indexing and is also used as a return type for the categories in `cut()` and `qcut()`.

Indexing with an IntervalIndex

An `IntervalIndex` can be used in `Series` and in `DataFrame` as the index.

```
In [192]: df = pd.DataFrame(
.....:     {"A": [1, 2, 3, 4]}, index=pd.IntervalIndex.from_breaks([0, 1, 2, 3, 4])
.....: )
.....:

In [193]: df
Out[193]:
      A
(0, 1]  1
(1, 2]  2
(2, 3]  3
(3, 4]  4
```

Label based indexing via `.loc` along the edges of an interval works as you would expect, selecting that particular interval.

```
In [194]: df.loc[2]
Out[194]:
A    2
Name: (1, 2], dtype: int64

In [195]: df.loc[[2, 3]]
Out[195]:
A
(1, 2]  2
(2, 3]  3
```

If you select a label *contained* within an interval, this will also select the interval.

```
In [196]: df.loc[2.5]
Out[196]:
A    3
Name: (2, 3], dtype: int64

In [197]: df.loc[[2.5, 3.5]]
Out[197]:
A
(2, 3]  3
(3, 4]  4
```

Selecting using an `Interval` will only return exact matches (starting from pandas 0.25.0).

```
In [198]: df.loc[pd.Interval(1, 2)]
Out[198]:
A    2
Name: (1, 2], dtype: int64
```

Trying to select an `Interval` that is not exactly contained in the `IntervalIndex` will raise a `KeyError`.

```
In [7]: df.loc[pd.Interval(0.5, 2.5)]
-----
KeyError: Interval(0.5, 2.5, closed='right')
```

Selecting all `Intervals` that overlap a given `Interval` can be performed using the `overlaps()` method to create a boolean indexer.

```
In [199]: idxr = df.index.overlaps(pd.Interval(0.5, 2.5))

In [200]: idxr
Out[200]: array([ True,  True,  True, False])

In [201]: df[idxr]
Out[201]:
A
(0, 1]  1
(1, 2]  2
(2, 3]  3
```

Binning data with `cut` and `qcut`

`cut()` and `qcut()` both return a Categorical object, and the bins they create are stored as an IntervalIndex in its `.categories` attribute.

```
In [202]: c = pd.cut(range(4), bins=2)
```

```
In [203]: c
```

```
Out[203]:
```

```
[(-0.003, 1.5], (-0.003, 1.5], (1.5, 3.0], (1.5, 3.0]]  
Categories (2, interval[float64, right]): [(-0.003, 1.5] < (1.5, 3.0)]
```

```
In [204]: c.categories
```

```
Out[204]: IntervalIndex([(-0.003, 1.5], (1.5, 3.0]], dtype='interval[float64, right]')
```

`cut()` also accepts an IntervalIndex for its `bins` argument, which enables a useful pandas idiom. First, We call `cut()` with some data and bins set to a fixed number, to generate the bins. Then, we pass the values of `.categories` as the `bins` argument in subsequent calls to `cut()`, supplying new data which will be binned into the same bins.

```
In [205]: pd.cut([0, 3, 5, 1], bins=c.categories)
```

```
Out[205]:
```

```
[(-0.003, 1.5], (1.5, 3.0], NaN, (-0.003, 1.5]]  
Categories (2, interval[float64, right]): [(-0.003, 1.5] < (1.5, 3.0)]
```

Any value which falls outside all bins will be assigned a `NaN` value.

Generating ranges of intervals

If we need intervals on a regular frequency, we can use the `interval_range()` function to create an IntervalIndex using various combinations of `start`, `end`, and `periods`. The default frequency for `interval_range` is a 1 for numeric intervals, and calendar day for datetime-like intervals:

```
In [206]: pd.interval_range(start=0, end=5)
```

```
Out[206]: IntervalIndex([(0, 1], (1, 2], (2, 3], (3, 4], (4, 5]], dtype='interval[int64, right]')
```

```
In [207]: pd.interval_range(start=pd.Timestamp("2017-01-01"), periods=4)
```

```
Out[207]: IntervalIndex([(2017-01-01, 2017-01-02], (2017-01-02, 2017-01-03], (2017-01-03, 2017-01-04], (2017-01-04, 2017-01-05]], dtype='interval[datetime64[ns], right]')
```

```
In [208]: pd.interval_range(end=pd.Timedelta("3 days"), periods=3)
```

```
Out[208]: IntervalIndex([(0 days 00:00:00, 1 days 00:00:00], (1 days 00:00:00, 2 days 00:00:00], (2 days 00:00:00, 3 days 00:00:00]], dtype='interval[timedelta64[ns], right]')
```

The `freq` parameter can be used to specify non-default frequencies, and can utilize a variety of `frequency aliases` with datetime-like intervals:

```
In [209]: pd.interval_range(start=0, periods=5, freq=1.5)
```

```
Out[209]: IntervalIndex([(0.0, 1.5], (1.5, 3.0], (3.0, 4.5], (4.5, 6.0], (6.0, 7.5]], dtype='interval[float64, right]')
```

```
In [210]: pd.interval_range(start=pd.Timestamp("2017-01-01"), periods=4, freq="W")
```

```
Out[210]: IntervalIndex([(2017-01-01, 2017-01-08], (2017-01-08, 2017-01-15], (2017-01-15, 2017-01-22], (2017-01-22, 2017-01-29]], dtype='interval[datetime64[ns], right]')
```

(continued from previous page)

```
In [211]: pd.interval_range(start=pd.Timedelta("0 days"), periods=3, freq="9H")
Out[211]: IntervalIndex([(0 days 00:00:00, 0 days 09:00:00], (0 days 09:00:00, 0 days 18:00:00], (0 days 18:00:00, 1 days 03:00:00]], dtype='interval[timedelta64[ns], right]')
```

Additionally, the `closed` parameter can be used to specify which side(s) the intervals are closed on. Intervals are closed on the right side by default.

```
In [212]: pd.interval_range(start=0, end=4, closed="both")
Out[212]: IntervalIndex([[0, 1], [1, 2], [2, 3], [3, 4]], dtype='interval[int64, both]')

In [213]: pd.interval_range(start=0, end=4, closed="neither")
Out[213]: IntervalIndex([(0, 1), (1, 2), (2, 3), (3, 4)], dtype='interval[int64, neither]')
```

Specifying `start`, `end`, and `periods` will generate a range of evenly spaced intervals from `start` to `end` inclusively, with `periods` number of elements in the resulting `IntervalIndex`:

```
In [214]: pd.interval_range(start=0, end=6, periods=4)
Out[214]: IntervalIndex([(0.0, 1.5], (1.5, 3.0], (3.0, 4.5], (4.5, 6.0]], dtype='interval[float64, right]'

In [215]: pd.interval_range(pd.Timestamp("2018-01-01"), pd.Timestamp("2018-02-28"), periods=3)
Out[215]: IntervalIndex([(2018-01-01, 2018-01-20 08:00:00], (2018-01-20 08:00:00, 2018-02-08 16:00:00], (2018-02-08 16:00:00, 2018-02-28]], dtype='interval[datetime64[ns], right]')
```

2.6.6 Miscellaneous indexing FAQ

Integer indexing

Label-based indexing with integer axis labels is a thorny topic. It has been discussed heavily on mailing lists and among various members of the scientific Python community. In pandas, our general viewpoint is that labels matter more than integer locations. Therefore, with an integer axis index *only* label-based indexing is possible with the standard tools like `.loc`. The following code will generate exceptions:

```
In [216]: s = pd.Series(range(5))

In [217]: s[-1]
-----
ValueError                                Traceback (most recent call last)
File /pandas/pandas/core/indexes/range.py:385, in RangeIndex.get_loc(self, key, method, tolerance)
    384     try:
--> 385         return self._range.index(new_key)
    386     except ValueError as err:
```

`ValueError: -1 is not in range`

The above exception was the direct cause of the following exception:

(continues on next page)

(continued from previous page)

```

KeyError                                     Traceback (most recent call last)

  385         return self._range.index(new_key)
  386     except ValueError as err:
--> 387         raise KeyError(key) from err
  388 self._check_indexing_error(key)
  389 raise KeyError(key)

KeyError: -1

In [218]: df = pd.DataFrame(np.random.randn(5, 4))

In [219]: df
Out[219]:
   0         1         2         3
0 -0.130121 -0.476046  0.759104  0.213379
1 -0.082641  0.448008  0.656420 -1.051443
2  0.594956 -0.151360 -0.069303  1.221431
3 -0.182832  0.791235  0.042745  2.069775
4  1.446552  0.019814 -1.389212 -0.702312

In [220]: df.loc[-2:]
Out[220]:
   0         1         2         3
0 -0.130121 -0.476046  0.759104  0.213379
1 -0.082641  0.448008  0.656420 -1.051443
2  0.594956 -0.151360 -0.069303  1.221431
3 -0.182832  0.791235  0.042745  2.069775
4  1.446552  0.019814 -1.389212 -0.702312

```

This deliberate decision was made to prevent ambiguities and subtle bugs (many users reported finding bugs when the API change was made to stop “falling back” on position-based indexing).

Non-monotonic indexes require exact matches

If the index of a Series or DataFrame is monotonically increasing or decreasing, then the bounds of a label-based slice can be outside the range of the index, much like slice indexing a normal Python list. Monotonicity of an index can be tested with the `is_monotonic_increasing()` and `is_monotonic_decreasing()` attributes.

```
In [221]: df = pd.DataFrame(index=[2, 3, 3, 4, 5], columns=["data"], data=list(range(5)))

In [222]: df.index.is_monotonic_increasing
Out[222]: True

# no rows 0 or 1, but still returns rows 2, 3 (both of them), and 4:
In [223]: df.loc[0:4, :]
Out[223]:
   data
2    0
3    1
3    2
4    3

# slice is outside the index, so empty DataFrame is returned
In [224]: df.loc[13:15, :]
Out[224]:
Empty DataFrame
Columns: [data]
Index: []
```

On the other hand, if the index is not monotonic, then both slice bounds must be *unique* members of the index.

```
In [225]: df = pd.DataFrame(index=[2, 3, 1, 4, 3, 5], columns=["data"], data=list(range(6)))

In [226]: df.index.is_monotonic_increasing
Out[226]: False

# OK because 2 and 4 are in the index
In [227]: df.loc[2:4, :]
Out[227]:
   data
2    0
3    1
1    2
4    3
```

```
# 0 is not in the index
In [9]: df.loc[0:4, :]
KeyError: 0

# 3 is not a unique label
In [11]: df.loc[2:3, :]
KeyError: 'Cannot get right slice bound for non-unique label: 3'
```

`Index.is_monotonic_increasing` and `Index.is_monotonic_decreasing` only check that an index is weakly monotonic. To check for strict monotonicity, you can combine one of those with the `is_unique()` attribute.

```
In [228]: weakly_monotonic = pd.Index(["a", "b", "c", "c"])

In [229]: weakly_monotonic
Out[229]: Index(['a', 'b', 'c', 'c'], dtype='object')

In [230]: weakly_monotonic.is_monotonic_increasing
Out[230]: True

In [231]: weakly_monotonic.is_monotonic_increasing & weakly_monotonic.is_unique
Out[231]: False
```

Endpoints are inclusive

Compared with standard Python sequence slicing in which the slice endpoint is not inclusive, label-based slicing in pandas **is inclusive**. The primary reason for this is that it is often not possible to easily determine the “successor” or next element after a particular label in an index. For example, consider the following Series:

```
In [232]: s = pd.Series(np.random.randn(6), index=list("abcdef"))

In [233]: s
Out[233]:
a    0.301379
b    1.240445
c   -0.846068
d   -0.043312
e   -1.658747
f   -0.819549
dtype: float64
```

Suppose we wished to slice from `c` to `e`, using integers this would be accomplished as such:

```
In [234]: s[2:5]
Out[234]:
c   -0.846068
d   -0.043312
e   -1.658747
dtype: float64
```

However, if you only had `c` and `e`, determining the next element in the index can be somewhat complicated. For example, the following does not work:

```
s.loc['c':'e' + 1]
```

A very common use case is to limit a time series to start and end at two specific dates. To enable this, we made the design choice to make label-based slicing include both endpoints:

```
In [235]: s.loc["c":"e"]
Out[235]:
c   -0.846068
d   -0.043312
e   -1.658747
dtype: float64
```

This is most definitely a “practicality beats purity” sort of thing, but it is something to watch out for if you expect label-based slicing to behave exactly in the way that standard Python integer slicing works.

Indexing potentially changes underlying Series dtype

The different indexing operation can potentially change the dtype of a Series.

```
In [236]: series1 = pd.Series([1, 2, 3])
```

```
In [237]: series1.dtype
```

```

```
2    NaN
```

```
dtype: object
```

This is because the (re)indexing operations above silently inserts NaNs and the dtype changes accordingly. This can cause some issues when using numpy ufuncs such as `numpy.logical_and`.

See the [GH2388](#) for a more detailed discussion.

2.7 Merge, join, concatenate and compare

pandas provides various facilities for easily combining together Series or DataFrame with various kinds of set logic for the indexes and relational algebra functionality in the case of join / merge-type operations.

In addition, pandas also provides utilities to compare two Series or DataFrame and summarize their differences.

2.7.1 Concatenating objects

The `concat()` function (in the main pandas namespace) does all of the heavy lifting of performing concatenation operations along an axis while performing optional set logic (union or intersection) of the indexes (if any) on the other axes. Note that I say “if any” because there is only a single possible axis of concatenation for Series.

Before diving into all of the details of `concat` and what it can do, here is a simple example:

```
In [1]: df1 = pd.DataFrame(  
...:     {  
...:         "A": ["A0", "A1", "A2", "A3"],  
...:         "B": ["B0", "B1", "B2", "B3"],  
...:         "C": ["C0", "C1", "C2", "C3"],  
...:         "D": ["D0", "D1", "D2", "D3"],  
...:     },  
...:     index=[0, 1, 2, 3],  
...: )  
  
In [2]: df2 = pd.DataFrame(  
...:     {  
...:         "A": ["A4", "A5", "A6", "A7"],  
...:         "B": ["B4", "B5", "B6", "B7"],  
...:         "C": ["C4", "C5", "C6", "C7"],  
...:         "D": ["D4", "D5", "D6", "D7"],  
...:     },  
...:     index=[4, 5, 6, 7],  
...: )  
  
In [3]: df3 = pd.DataFrame(  
...:     {  
...:         "A": ["A8", "A9", "A10", "A11"],  
...:         "B": ["B8", "B9", "B10", "B11"],  
...:         "C": ["C8", "C9", "C10", "C11"],  
...:         "D": ["D8", "D9", "D10", "D11"],  
...:     },  
...:     index=[8, 9, 10, 11],  
...: )  
  
In [4]: frames = [df1, df2, df3]  
  
In [5]: result = pd.concat(frames)
```

df1					Result				
	A	B	C	D		A	B	C	D
0	A0	B0	C0	D0	0	A0	B0	C0	D0
1	A1	B1	C1	D1	1	A1	B1	C1	D1
2	A2	B2	C2	D2	2	A2	B2	C2	D2
3	A3	B3	C3	D3	3	A3	B3	C3	D3
df2					Result				
	A	B	C	D		A	B	C	D
4	A4	B4	C4	D4	4	A4	B4	C4	D4
5	A5	B5	C5	D5	5	A5	B5	C5	D5
6	A6	B6	C6	D6	6	A6	B6	C6	D6
7	A7	B7	C7	D7	7	A7	B7	C7	D7
df3					Result				
	A	B	C	D		A	B	C	D
8	A8	B8	C8	D8	8	A8	B8	C8	D8
9	A9	B9	C9	D9	9	A9	B9	C9	D9
10	A10	B10	C10	D10	10	A10	B10	C10	D10
11	A11	B11	C11	D11	11	A11	B11	C11	D11

Like its sibling function on ndarrays, `numpy.concatenate`, `pandas.concat` takes a list or dict of homogeneously-typed objects and concatenates them with some configurable handling of “what to do with the other axes”:

```
pd.concat(
    objs,
    axis=0,
    join="outer",
    ignore_index=False,
    keys=None,
    levels=None,
    names=None,
    verify_integrity=False,
    copy=True,
)
```

- `objs` : a sequence or mapping of Series or DataFrame objects. If a dict is passed, the sorted keys will be used as the `keys` argument, unless it is passed, in which case the values will be selected (see below). Any `None` objects will be dropped silently unless they are all `None` in which case a `ValueError` will be raised.
- `axis` : {0, 1, ...}, default 0. The axis to concatenate along.
- `join` : {'inner', 'outer'}, default 'outer'. How to handle indexes on other axis(es). Outer for union and inner for intersection.
- `ignore_index` : boolean, default False. If True, do not use the index values on the concatenation axis. The resulting axis will be labeled 0, ..., n - 1. This is useful if you are concatenating objects where the concatenation axis does not have meaningful indexing information. Note the index values on the other axes are still respected in the join.

- **keys** : sequence, default None. Construct hierarchical index using the passed keys as the outermost level. If multiple levels passed, should contain tuples.
- **levels** : list of sequences, default None. Specific levels (unique values) to use for constructing a MultiIndex. Otherwise they will be inferred from the keys.
- **names** : list, default None. Names for the levels in the resulting hierarchical index.
- **verify_integrity** : boolean, default False. Check whether the new concatenated axis contains duplicates. This can be very expensive relative to the actual data concatenation.
- **copy** : boolean, default True. If False, do not copy data unnecessarily.

Without a little bit of context many of these arguments don't make much sense. Let's revisit the above example. Suppose we wanted to associate specific keys with each of the pieces of the chopped up DataFrame. We can do this using the `keys` argument:

```
In [6]: result = pd.concat(frames, keys=["x", "y", "z"])
```

df1				Result						
	A	B	C	D		A	B	C	D	
0	A0	B0	C0	D0	x	0	A0	B0	C0	D0
1	A1	B1	C1	D1	x	1	A1	B1	C1	D1
2	A2	B2	C2	D2	x	2	A2	B2	C2	D2
3	A3	B3	C3	D3	x	3	A3	B3	C3	D3
df2				y	4	A4	B4	C4	D4	
df3				y	5	A5	B5	C5	D5	
4	A4	B4	C4	D4	y	6	A6	B6	C6	D6
5	A5	B5	C5	D5	y	7	A7	B7	C7	D7
6	A6	B6	C6	D6	z	8	A8	B8	C8	D8
7	A7	B7	C7	D7	z	9	A9	B9	C9	D9
df1				z	10	A10	B10	C10	D10	
df2				z	11	A11	B11	C11	D11	
8	A8	B8	C8	D8						
9	A9	B9	C9	D9						
10	A10	B10	C10	D10						
11	A11	B11	C11	D11						

As you can see (if you've read the rest of the documentation), the resulting object's index has a [hierarchical index](#). This means that we can now select out each chunk by key:

```
In [7]: result.loc["y"]
```

Out[7]:

	A	B	C	D
4	A4	B4	C4	D4
5	A5	B5	C5	D5
6	A6	B6	C6	D6
7	A7	B7	C7	D7

It's not a stretch to see how this can be very useful. More detail on this functionality below.

Note: It is worth noting that `concat()` (and therefore `append()`) makes a full copy of the data, and that constantly reusing this function can create a significant performance hit. If you need to use the operation over several datasets, use a list comprehension.

```
frames = [ process_your_file(f) for f in files ]
result = pd.concat(frames)
```

Note: When concatenating DataFrames with named axes, pandas will attempt to preserve these index/column names whenever possible. In the case where all inputs share a common name, this name will be assigned to the result. When the input names do not all agree, the result will be unnamed. The same is true for `MultiIndex`, but the logic is applied separately on a level-by-level basis.

Set logic on the other axes

When gluing together multiple DataFrames, you have a choice of how to handle the other axes (other than the one being concatenated). This can be done in the following two ways:

- Take the union of them all, `join='outer'`. This is the default option as it results in zero information loss.
- Take the intersection, `join='inner'`.

Here is an example of each of these methods. First, the default `join='outer'` behavior:

```
In [8]: df4 = pd.DataFrame(
...:     {
...:         "B": ["B2", "B3", "B6", "B7"],
...:         "D": ["D2", "D3", "D6", "D7"],
...:         "F": ["F2", "F3", "F6", "F7"],
...:     },
...:     index=[2, 3, 6, 7],
...: )
```

```
In [9]: result = pd.concat([df1, df4], axis=1)
```

df1				df4			Result									
	A	B	C	D	B	D	F	A	B	C	D	B	D	F		
0	A0	B0	C0	D0	2	B2	D2	F2	0	A0	B0	C0	D0	NaN	NaN	NaN
1	A1	B1	C1	D1	3	B3	D3	F3	1	A1	B1	C1	D1	NaN	NaN	NaN
2	A2	B2	C2	D2	6	B6	D6	F6	2	A2	B2	C2	D2	B2	D2	F2
3	A3	B3	C3	D3	7	B7	D7	F7	3	A3	B3	C3	D3	B3	D3	F3
									6	NaN	NaN	NaN	NaN	B6	D6	F6
									7	NaN	NaN	NaN	NaN	B7	D7	F7

Here is the same thing with `join='inner'`:

```
In [10]: result = pd.concat([df1, df4], axis=1, join="inner")
```

	df1				df4			Result								
	A	B	C	D	B	D	F	A	B	C	D	B	D	F		
0	A0	B0	C0	D0	2	B2	D2	F2	2	A2	B2	C2	D2	B2	D2	F2
1	A1	B1	C1	D1	3	B3	D3	F3	3	A3	B3	C3	D3	B3	D3	F3
2	A2	B2	C2	D2	6	B6	D6	F6								
3	A3	B3	C3	D3	7	B7	D7	F7								

Lastly, suppose we just wanted to reuse the *exact index* from the original DataFrame:

```
In [11]: result = pd.concat([df1, df4], axis=1).reindex(df1.index)
```

Similarly, we could index before the concatenation:

```
In [12]: pd.concat([df1, df4.reindex(df1.index)], axis=1)
```

Out[12]:

	A	B	C	D	B	D	F
0	A0	B0	C0	D0	NaN	NaN	NaN
1	A1	B1	C1	D1	NaN	NaN	NaN
2	A2	B2	C2	D2	B2	D2	F2
3	A3	B3	C3	D3	B3	D3	F3

	df1				df4			Result								
	A	B	C	D	B	D	F	A	B	C	D	B	D	F		
0	A0	B0	C0	D0	2	B2	D2	F2	0	A0	B0	C0	D0	NaN	NaN	NaN
1	A1	B1	C1	D1	3	B3	D3	F3	1	A1	B1	C1	D1	NaN	NaN	NaN
2	A2	B2	C2	D2	6	B6	D6	F6	2	A2	B2	C2	D2	B2	D2	F2
3	A3	B3	C3	D3	7	B7	D7	F7	3	A3	B3	C3	D3	B3	D3	F3

Ignoring indexes on the concatenation axis

For DataFrame objects which don't have a meaningful index, you may wish to append them and ignore the fact that they may have overlapping indexes. To do this, use the `ignore_index=True` argument:

```
In [13]: result = pd.concat([df1, df4], ignore_index=True, sort=False)
```

df1				Result	
	A	B	C	D	F
0	A0	B0	C0	D0	NaN
1	A1	B1	C1	D1	NaN
2	A2	B2	C2	D2	NaN
3	A3	B3	C3	D3	NaN

df4			Result		
	B	D	F		
2	B2	D2	F2		
3	B3	D3	F3		
6	B6	D6	F6		
7	B7	D7	F7		

Concatenating with mixed ndims

You can concatenate a mix of Series and DataFrame objects. The Series will be transformed to DataFrame with the column name as the name of the Series.

```
In [14]: s1 = pd.Series(["X0", "X1", "X2", "X3"], name="X")
```

```
In [15]: result = pd.concat([df1, s1], axis=1)
```

df1				s1	Result					
	A	B	C	D	X	A	B	C	D	X
0	A0	B0	C0	D0	X0	A0	B0	C0	D0	X0
1	A1	B1	C1	D1	X1	A1	B1	C1	D1	X1
2	A2	B2	C2	D2	X2	A2	B2	C2	D2	X2
3	A3	B3	C3	D3	X3	A3	B3	C3	D3	X3

Note: Since we're concatenating a Series to a DataFrame, we could have achieved the same result with `DataFrame.assign()`. To concatenate an arbitrary number of pandas objects (DataFrame or Series), use `concat`.

If unnamed Series are passed they will be numbered consecutively.

```
In [16]: s2 = pd.Series(["_0", "_1", "_2", "_3"])
```

```
In [17]: result = pd.concat([df1, s2, s2, s2], axis=1)
```

	df1				s2		Result							
	A	B	C	D	0	_0	0	A0	B0	C0	D0	0	1	2
0	A0	B0	C0	D0	0	_0	0	A0	B0	C0	D0	_0	_0	_0
1	A1	B1	C1	D1	1	_1	1	A1	B1	C1	D1	_1	_1	_1
2	A2	B2	C2	D2	2	_2	2	A2	B2	C2	D2	_2	_2	_2
3	A3	B3	C3	D3	3	_3	3	A3	B3	C3	D3	_3	_3	_3

Passing `ignore_index=True` will drop all name references.

```
In [18]: result = pd.concat([df1, s1], axis=1, ignore_index=True)
```

	df1				s1		Result				
	A	B	C	D	X		0	1	2	3	4
0	A0	B0	C0	D0	X0	0	A0	B0	C0	D0	X0
1	A1	B1	C1	D1	X1	1	A1	B1	C1	D1	X1
2	A2	B2	C2	D2	X2	2	A2	B2	C2	D2	X2
3	A3	B3	C3	D3	X3	3	A3	B3	C3	D3	X3

More concatenating with group keys

A fairly common use of the `keys` argument is to override the column names when creating a new DataFrame based on existing Series. Notice how the default behaviour consists on letting the resulting DataFrame inherit the parent Series' name, when these existed.

```
In [19]: s3 = pd.Series([0, 1, 2, 3], name="foo")
```

```
In [20]: s4 = pd.Series([0, 1, 2, 3])
```

```
In [21]: s5 = pd.Series([0, 1, 4, 5])
```

```
In [22]: pd.concat([s3, s4, s5], axis=1)
```

Out[22]:

foo	0	1
0	0	0
1	1	1
2	2	2
3	3	5

Through the `keys` argument we can override the existing column names.

```
In [23]: pd.concat([s3, s4, s5], axis=1, keys=["red", "blue", "yellow"])
```

Out[23]:

	red	blue	yellow
0	0	0	0
1	1	1	1
2	2	2	4
3	3	3	5

Let's consider a variation of the very first example presented:

```
In [24]: result = pd.concat(frames, keys=["x", "y", "z"])
```

df1				Result					
	A	B	C	D	A	B	C	D	
0	A0	B0	C0	D0	x 0	AD	BD	CD	DD
1	A1	B1	C1	D1	x 1	A1	B1	C1	D1
2	A2	B2	C2	D2	x 2	A2	B2	C2	D2
3	A3	B3	C3	D3	x 3	A3	B3	C3	D3
df2				Result					
	A	B	C	D	A	B	C	D	
4	A4	B4	C4	D4	y 4	A4	B4	C4	D4
5	A5	B5	C5	D5	y 5	A5	B5	C5	D5
6	A6	B6	C6	D6	y 6	A6	B6	C6	D6
7	A7	B7	C7	D7	y 7	A7	B7	C7	D7
df3				Result					
	A	B	C	D	A	B	C	D	
8	A8	B8	C8	D8	z 8	AB	BB	CB	DB
9	A9	B9	C9	D9	z 9	A9	B9	C9	D9
10	A10	B10	C10	D10	z 10	A10	B10	C10	D10
11	A11	B11	C11	D11	z 11	A11	B11	C11	D11

You can also pass a dict to `concat` in which case the dict keys will be used for the `keys` argument (unless other keys are specified):

```
In [25]: pieces = {"x": df1, "y": df2, "z": df3}
```

```
In [26]: result = pd.concat(pieces)
```

df1					Result					
	A	B	C	D		A	B	C	D	
0	A0	B0	C0	D0	x	0	AD	BD	CD	DD
1	A1	B1	C1	D1	x	1	A1	B1	C1	D1
2	A2	B2	C2	D2	x	2	A2	B2	C2	D2
3	A3	B3	C3	D3	x	3	A3	B3	C3	D3
df2					y	4	A4	B4	C4	D4
df3					y	5	A5	B5	C5	D5
df4					y	6	A6	B6	C6	D6
df5					y	7	A7	B7	C7	D7
df6					z	8	AB	BB	CB	DB
df7					z	9	AB	BB	CB	DB
df8					z	10	A10	B10	C10	D10
df9					z	11	A11	B11	C11	D11

```
In [27]: result = pd.concat(pieces, keys=["z", "y"])
```

df1					Result					
	A	B	C	D		A	B	C	D	
0	A0	B0	C0	D0	z	8	AB	BB	CB	DB
1	A1	B1	C1	D1	z	9	AB	BB	CB	DB
2	A2	B2	C2	D2	z	10	A10	B10	C10	D10
3	A3	B3	C3	D3	z	11	A11	B11	C11	D11
df2					y	4	A4	B4	C4	D4
df3					y	5	A5	B5	C5	D5
df4					y	6	A6	B6	C6	D6
df5					y	7	A7	B7	C7	D7
df6										
df7										
df8										
df9										

The MultiIndex created has levels that are constructed from the passed keys and the index of the DataFrame pieces:

```
In [28]: result.index.levels
```

```
Out[28]: FrozenList([['z', 'y'], [4, 5, 6, 7, 8, 9, 10, 11]])
```

If you wish to specify other levels (as will occasionally be the case), you can do so using the `levels` argument:

```
In [29]: result = pd.concat(
.....      pieces, keys=["x", "y", "z"], levels=[["z", "y", "x", "w"]], names=["group_"
↳key"])
.....)
```

df1					Result				
	A	B	C	D		A	B	C	D
0	A0	B0	C0	D0	x 0	A0	B0	C0	D0
1	A1	B1	C1	D1	x 1	A1	B1	C1	D1
2	A2	B2	C2	D2	x 2	A2	B2	C2	D2
3	A3	B3	C3	D3	x 3	A3	B3	C3	D3
df2						A	B	C	D
	A	B	C	D		A	B	C	D
4	A4	B4	C4	D4	y 4	A4	B4	C4	D4
5	A5	B5	C5	D5	y 5	A5	B5	C5	D5
6	A6	B6	C6	D6	y 6	A6	B6	C6	D6
7	A7	B7	C7	D7	y 7	A7	B7	C7	D7
df3						A	B	C	D
	A	B	C	D		A	B	C	D
8	A8	B8	C8	D8	z 8	A8	B8	C8	D8
9	A9	B9	C9	D9	z 9	A9	B9	C9	D9
10	A10	B10	C10	D10	z 10	A10	B10	C10	D10
11	A11	B11	C11	D11	z 11	A11	B11	C11	D11

```
In [30]: result.index.levels
```

```
Out[30]: FrozenList([['z', 'y', 'x', 'w'], [0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11]])
```

This is fairly esoteric, but it is actually necessary for implementing things like GroupBy where the order of a categorical variable is meaningful.

Appending rows to a DataFrame

If you have a series that you want to append as a single row to a DataFrame, you can convert the row into a DataFrame and use `concat`

```
In [31]: s2 = pd.Series(["X0", "X1", "X2", "X3"], index=["A", "B", "C", "D"])
```

```
In [32]: result = pd.concat([df1, s2.to_frame().T], ignore_index=True)
```

	A	B	C	D
0	A0	B0	C0	D0
1	A1	B1	C1	D1
2	A2	B2	C2	D2
3	A3	B3	C3	D3

s2

	A	B	C	D
A	X0			
B		X1		
C			X2	
D				X3

	A	B	C	D
0	A0	B0	C0	D0
1	A1	B1	C1	D1
2	A2	B2	C2	D2
3	A3	B3	C3	D3
4	X0	X1	X2	X3

You should use `ignore_index` with this method to instruct DataFrame to discard its index. If you wish to preserve the index, you should construct an appropriately-indexed DataFrame and append or concatenate those objects.

2.7.2 Database-style DataFrame or named Series joining/merging

pandas has full-featured, **high performance** in-memory join operations idiomatically very similar to relational databases like SQL. These methods perform significantly better (in some cases well over an order of magnitude better) than other open source implementations (like `base::merge.data.frame` in R). The reason for this is careful algorithmic design and the internal layout of the data in DataFrame.

See the [cookbook](#) for some advanced strategies.

Users who are familiar with SQL but new to pandas might be interested in a [comparison with SQL](#).

pandas provides a single function, `merge()`, as the entry point for all standard database join operations between DataFrame or named Series objects:

```
pd.merge(
    left,
    right,
    how="inner",
    on=None,
    left_on=None,
    right_on=None,
    left_index=False,
    right_index=False,
    sort=True,
```

(continues on next page)

(continued from previous page)

```

    suffixes=("_x", "_y"),
    copy=True,
    indicator=False,
    validate=None,
)

```

- **left:** A DataFrame or named Series object.
- **right:** Another DataFrame or named Series object.
- **on:** Column or index level names to join on. Must be found in both the left and right DataFrame and/or Series objects. If not passed and `left_index` and `right_index` are `False`, the intersection of the columns in the DataFrames and/or Series will be inferred to be the join keys.
- **left_on:** Columns or index levels from the left DataFrame or Series to use as keys. Can either be column names, index level names, or arrays with length equal to the length of the DataFrame or Series.
- **right_on:** Columns or index levels from the right DataFrame or Series to use as keys. Can either be column names, index level names, or arrays with length equal to the length of the DataFrame or Series.
- **left_index:** If `True`, use the index (row labels) from the left DataFrame or Series as its join key(s). In the case of a DataFrame or Series with a MultiIndex (hierarchical), the number of levels must match the number of join keys from the right DataFrame or Series.
- **right_index:** Same usage as `left_index` for the right DataFrame or Series
- **how:** One of '`left`', '`right`', '`outer`', '`inner`', '`cross`'. Defaults to `inner`. See below for more detailed description of each method.
- **sort:** Sort the result DataFrame by the join keys in lexicographical order. Defaults to `True`, setting to `False` will improve performance substantially in many cases.
- **suffixes:** A tuple of string suffixes to apply to overlapping columns. Defaults to ('`_x`', '`_y`').
- **copy:** Always copy data (default `True`) from the passed DataFrame or named Series objects, even when reindexing is not necessary. Cannot be avoided in many cases but may improve performance / memory usage. The cases where copying can be avoided are somewhat pathological but this option is provided nonetheless.
- **indicator:** Add a column to the output DataFrame called `_merge` with information on the source of each row. `_merge` is Categorical-type and takes on a value of `left_only` for observations whose merge key only appears in 'left' DataFrame or Series, `right_only` for observations whose merge key only appears in 'right' DataFrame or Series, and `both` if the observation's merge key is found in both.
- **validate :** string, default `None`. If specified, checks if merge is of specified type.
 - “one_to_one” or “1:1”: checks if merge keys are unique in both left and right datasets.
 - “one_to_many” or “1:m”: checks if merge keys are unique in left dataset.
 - “many_to_one” or “m:1”: checks if merge keys are unique in right dataset.
 - “many_to_many” or “m:m”: allowed, but does not result in checks.

Note: Support for specifying index levels as the `on`, `left_on`, and `right_on` parameters was added in version 0.23.0. Support for merging named Series objects was added in version 0.24.0.

The return type will be the same as `left`. If `left` is a DataFrame or named Series and `right` is a subclass of DataFrame, the return type will still be DataFrame.

`merge` is a function in the pandas namespace, and it is also available as a `DataFrame` instance method `merge()`, with the calling `DataFrame` being implicitly considered the left object in the join.

The related `join()` method, uses `merge` internally for the index-on-index (by default) and column(s)-on-index join. If you are joining on index only, you may wish to use `DataFrame.join` to save yourself some typing.

Brief primer on merge methods (relational algebra)

Experienced users of relational databases like SQL will be familiar with the terminology used to describe join operations between two SQL-table like structures (`DataFrame` objects). There are several cases to consider which are very important to understand:

- **one-to-one** joins: for example when joining two `DataFrame` objects on their indexes (which must contain unique values).
- **many-to-one** joins: for example when joining an index (unique) to one or more columns in a different `DataFrame`.
- **many-to-many** joins: joining columns on columns.

Note: When joining columns on columns (potentially a many-to-many join), any indexes on the passed `DataFrame` objects **will be discarded**.

It is worth spending some time understanding the result of the **many-to-many** join case. In SQL / standard relational algebra, if a key combination appears more than once in both tables, the resulting table will have the **Cartesian product** of the associated data. Here is a very basic example with one unique key combination:

```
In [33]: left = pd.DataFrame(  
.....    {  
.....        "key": ["K0", "K1", "K2", "K3"],  
.....        "A": ["A0", "A1", "A2", "A3"],  
.....        "B": ["B0", "B1", "B2", "B3"],  
.....    }  
.....)  
.....  
In [34]: right = pd.DataFrame(  
.....    {  
.....        "key": ["K0", "K1", "K2", "K3"],  
.....        "C": ["C0", "C1", "C2", "C3"],  
.....        "D": ["D0", "D1", "D2", "D3"],  
.....    }  
.....)  
.....  
In [35]: result = pd.merge(left, right, on="key")
```

left			right			Result							
	key	A		key	C	D		key	A	B	C	D	
0	K0	A0	B0	0	K0	C0	D0	0	K0	A0	B0	C0	D0
1	K1	A1	B1	1	K1	C1	D1	1	K1	A1	B1	C1	D1
2	K2	A2	B2	2	K2	C2	D2	2	K2	A2	B2	C2	D2
3	K3	A3	B3	3	K3	C3	D3	3	K3	A3	B3	C3	D3

Here is a more complicated example with multiple join keys. Only the keys appearing in `left` and `right` are present (the intersection), since `how='inner'` by default.

```
In [36]: left = pd.DataFrame(
...:     {
...:         "key1": ["K0", "K0", "K1", "K2"],
...:         "key2": ["K0", "K1", "K0", "K1"],
...:         "A": ["A0", "A1", "A2", "A3"],
...:         "B": ["B0", "B1", "B2", "B3"],
...:     }
...: )
```

```
In [37]: right = pd.DataFrame(
...:     {
...:         "key1": ["K0", "K1", "K1", "K2"],
...:         "key2": ["K0", "K0", "K0", "K0"],
...:         "C": ["C0", "C1", "C2", "C3"],
...:         "D": ["D0", "D1", "D2", "D3"],
...:     }
...: )
```

```
In [38]: result = pd.merge(left, right, on=["key1", "key2"])
```

left				right				Result						
	key1	key2	A		key1	key2	C	D		key1	key2	A	B	
0	K0	K0	A0	B0	0	K0	K0	C0	D0	0	K0	K0	A0	B0
1	K0	K1	A1	B1	1	K1	K0	C1	D1	1	K1	K0	A2	B2
2	K1	K0	A2	B2	2	K1	K0	C2	D2	2	K1	K0	A2	B2
3	K2	K1	A3	B3	3	K2	K0	C3	D3					

The `how` argument to `merge` specifies how to determine which keys are to be included in the resulting table. If a key combination **does not appear** in either the left or right tables, the values in the joined table will be `NA`. Here is a summary of the `how` options and their SQL equivalent names:

Merge method	SQL Join Name	Description
left	LEFT OUTER JOIN	Use keys from left frame only
right	RIGHT OUTER JOIN	Use keys from right frame only
outer	FULL OUTER JOIN	Use union of keys from both frames
inner	INNER JOIN	Use intersection of keys from both frames
cross	CROSS JOIN	Create the cartesian product of rows of both frames

```
In [39]: result = pd.merge(left, right, how="left", on=["key1", "key2"])
```

left		right		Result			
key1	key2	A	B	key1	key2	C	D
0	K0	K0	A0	B0	0	K0	D0
1	K0	K1	A1	B1	1	K1	D1
2	K1	K0	A2	B2	2	K0	C2
3	K2	K1	A3	B3	3	K2	D3

```
In [40]: result = pd.merge(left, right, how="right", on=["key1", "key2"])
```

left		right		Result			
key1	key2	A	B	key1	key2	C	D
0	K0	K0	A0	B0	0	K0	D0
1	K0	K1	A1	B1	1	K1	C1
2	K1	K0	A2	B2	2	K0	C2
3	K2	K1	A3	B3	3	K2	D3

```
In [41]: result = pd.merge(left, right, how="outer", on=["key1", "key2"])
```

left		right		Result			
key1	key2	A	B	key1	key2	C	D
0	K0	K0	A0	B0	0	K0	D0
1	K0	K1	A1	B1	1	K1	NaN
2	K1	K0	A2	B2	2	K0	C1
3	K2	K1	A3	B3	3	K1	D2
				4	K2	K1	NaN
				5	K2	K0	C3

```
In [42]: result = pd.merge(left, right, how="inner", on=["key1", "key2"])
```

left				right				Result							
	key1	key2	A		key1	key2	C		key1	key2	A	B	C	D	
0	K0	K0	A0	B0	0	K0	C0	D0	0	K0	K0	A0	B0	C0	D0
1	K0	K1	A1	B1	1	K1	K0	C1	1	K1	K0	A2	B2	C1	D1
2	K1	K0	A2	B2	2	K1	K0	C2	2	K1	K0	A2	B2	C2	D2
3	K2	K1	A3	B3	3	K2	K0	C3	3	K2	K0				

```
In [43]: result = pd.merge(left, right, how="cross")
```

left				right				Result									
	key1	key2	A		key1	key2	C		key1_x	key2_x	A	B	key1_y	key2_y	C	D	
0	K0	K0	A0	B0	0	K0	C0	D0	0	K0	A0	B0	K0	K0	C0	D0	
1	K0	K1	A1	B1	1	K1	K0	C1	1	K0	A1	B0	K1	K0	C1	D1	
2	K1	K0	A2	B2	2	K1	K0	C2	2	K0	A2	B0	K1	K0	C2	D2	
3	K2	K1	A3	B3	3	K2	K0	C3	3	K0	A3	B0	K2	K0	C3	D3	
									4	K0	K1	A1	B1	K0	C0	D0	
									5	K0	K1	A1	B1	K1	K0	C1	D1
									6	K0	K1	A1	B1	K1	K0	C2	D2
									7	K0	K1	A1	B1	K2	K0	C3	D3
									8	K1	K0	A2	B2	K0	K0	C0	D0
									9	K1	K0	A2	B2	K1	K0	C1	D1
									10	K1	K0	A2	B2	K1	K0	C2	D2
									11	K1	K0	A2	B2	K2	K0	C3	D3
									12	K2	K1	A3	B3	K0	K0	C0	D0
									13	K2	K1	A3	B3	K1	K0	C1	D1
									14	K2	K1	A3	B3	K1	K0	C2	D2
									15	K2	K1	A3	B3	K2	K0	C3	D3

You can merge a mult-indexed Series and a DataFrame, if the names of the MultiIndex correspond to the columns from the DataFrame. Transform the Series to a DataFrame using `Series.reset_index()` before merging, as shown in the following example.

```
In [44]: df = pd.DataFrame({"Let": ["A", "B", "C"], "Num": [1, 2, 3]})
```

```
In [45]: df
```

```
Out[45]:
```

Let	Num
0	A 1
1	B 2

(continues on next page)

(continued from previous page)

2 C 3

```
In [46]: ser = pd.Series(
....:     ["a", "b", "c", "d", "e", "f"],
....:     index=pd.MultiIndex.from_arrays(
....:         [[["A", "B", "C"] * 2, [1, 2, 3, 4, 5, 6]], names=["Let", "Num"]
....:     ),
....: )
....:
```

In [47]: ser

Out[47]:

	Let	Num	
A	1	a	
B	2	b	
C	3	c	
A	4	d	
B	5	e	
C	6	f	

dtype: object

In [48]: pd.merge(df, ser.reset_index(), on=["Let", "Num"])

Out[48]:

	Let	Num	0
0	A	1	a
1	B	2	b
2	C	3	c

Here is another example with duplicate join keys in DataFrames:

In [49]: left = pd.DataFrame({"A": [1, 2], "B": [2, 2]})

In [50]: right = pd.DataFrame({"A": [4, 5, 6], "B": [2, 2, 2]})

In [51]: result = pd.merge(left, right, on="B", how="outer")

left	right	Result																																																	
<table border="1"> <thead> <tr> <th></th> <th>A</th> <th>B</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>1</td> <td>2</td> </tr> <tr> <td>1</td> <td>2</td> <td>2</td> </tr> </tbody> </table>		A	B	0	1	2	1	2	2	<table border="1"> <thead> <tr> <th></th> <th>A</th> <th>B</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>4</td> <td>2</td> </tr> <tr> <td>1</td> <td>5</td> <td>2</td> </tr> <tr> <td>2</td> <td>6</td> <td>2</td> </tr> </tbody> </table>		A	B	0	4	2	1	5	2	2	6	2	<table border="1"> <thead> <tr> <th></th> <th>A_x</th> <th>B</th> <th>A_y</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>1</td> <td>2</td> <td>4</td> </tr> <tr> <td>1</td> <td>1</td> <td>2</td> <td>5</td> </tr> <tr> <td>2</td> <td>1</td> <td>2</td> <td>6</td> </tr> <tr> <td>3</td> <td>2</td> <td>2</td> <td>4</td> </tr> <tr> <td>4</td> <td>2</td> <td>2</td> <td>5</td> </tr> <tr> <td>5</td> <td>2</td> <td>2</td> <td>6</td> </tr> </tbody> </table>		A_x	B	A_y	0	1	2	4	1	1	2	5	2	1	2	6	3	2	2	4	4	2	2	5	5	2	2	6
	A	B																																																	
0	1	2																																																	
1	2	2																																																	
	A	B																																																	
0	4	2																																																	
1	5	2																																																	
2	6	2																																																	
	A_x	B	A_y																																																
0	1	2	4																																																
1	1	2	5																																																
2	1	2	6																																																
3	2	2	4																																																
4	2	2	5																																																
5	2	2	6																																																

Warning: Joining / merging on duplicate keys can cause a returned frame that is the multiplication of the row dimensions, which may result in memory overflow. It is the user's responsibility to manage duplicate values in keys before joining large DataFrames.

Checking for duplicate keys

Users can use the `validate` argument to automatically check whether there are unexpected duplicates in their merge keys. Key uniqueness is checked before merge operations and so should protect against memory overflows. Checking key uniqueness is also a good way to ensure user data structures are as expected.

In the following example, there are duplicate values of B in the right DataFrame. As this is not a one-to-one merge – as specified in the `validate` argument – an exception will be raised.

```
In [52]: left = pd.DataFrame({"A": [1, 2], "B": [1, 2]})
```

```
In [53]: right = pd.DataFrame({"A": [4, 5, 6], "B": [2, 2, 2]})
```

```
In [53]: result = pd.merge(left, right, on="B", how="outer", validate="one_to_one")
```

```
...
```

```
MergeError: Merge keys are not unique in right dataset; not a one-to-one merge
```

If the user is aware of the duplicates in the right DataFrame but wants to ensure there are no duplicates in the left DataFrame, one can use the `validate='one_to_many'` argument instead, which will not raise an exception.

```
In [54]: pd.merge(left, right, on="B", how="outer", validate="one_to_many")
```

```
Out[54]:
```

	A_x	B	A_y
0	1	1	NaN
1	2	2	4.0
2	2	2	5.0
3	2	2	6.0

The merge indicator

`merge()` accepts the argument `indicator`. If True, a Categorical-type column called `_merge` will be added to the output object that takes on values:

Observation Origin	_merge value
Merge key only in 'left' frame	left_only
Merge key only in 'right' frame	right_only
Merge key in both frames	both

```
In [55]: df1 = pd.DataFrame({"col1": [0, 1], "col_left": ["a", "b"]})
```

```
In [56]: df2 = pd.DataFrame({"col1": [1, 2, 2], "col_right": [2, 2, 2]})
```

```
In [57]: pd.merge(df1, df2, on="col1", how="outer", indicator=True)
```

```
Out[57]:
```

col1	col_left	col_right	_merge
0	a		left_only
1	b	2	right_only
2		2	both

(continues on next page)

(continued from previous page)

0	0	a	NaN	left_only
1	1	b	2.0	both
2	2	NaN	2.0	right_only
3	2	NaN	2.0	right_only

The `indicator` argument will also accept string arguments, in which case the indicator function will use the value of the passed string as the name for the indicator column.

```
In [58]: pd.merge(df1, df2, on="col1", how="outer", indicator="indicator_column")
```

Out[58]:

	col1	col_left	col_right	indicator_column
0	0	a	NaN	left_only
1	1	b	2.0	both
2	2	NaN	2.0	right_only
3	2	NaN	2.0	right_only

Merge dtypes

Merging will preserve the dtype of the join keys.

```
In [59]: left = pd.DataFrame({"key": [1], "v1": [10]})
```

In [60]: left

Out[60]:

	key	v1
0	1	10

```
In [61]: right = pd.DataFrame({"key": [1, 2], "v1": [20, 30]})
```

In [62]: right

Out[62]:

	key	v1
0	1	20
1	2	30

We are able to preserve the join keys:

```
In [63]: pd.merge(left, right, how="outer")
```

Out[63]:

	key	v1
0	1	10
1	1	20
2	2	30

```
In [64]: pd.merge(left, right, how="outer").dtypes
```

Out[64]:

key	int64
v1	int64
dtype:	object

Of course if you have missing values that are introduced, then the resulting dtype will be upcast.

```
In [65]: pd.merge(left, right, how="outer", on="key")
```

```
Out[65]:
```

	key	v1_x	v1_y
0	1	10.0	20
1	2	NaN	30

```
In [66]: pd.merge(left, right, how="outer", on="key").dtypes
```

```
Out[66]:
```

	key	v1_x	v1_y
	int64	float64	int64
			dtype: object

Merging will preserve category dtypes of the mergands. See also the section on [categoricals](#).

The left frame.

```
In [67]: from pandas.api.types import CategoricalDtype
```

```
In [68]: X = pd.Series(np.random.choice(["foo", "bar"], size=(10,)))
```

```
In [69]: X = X.astype(CategoricalDtype(categories=["foo", "bar"]))
```

```
In [70]: left = pd.DataFrame(
.....:     {"X": X, "Y": np.random.choice(["one", "two", "three"], size=(10,))}
.....:
.....:
```

```
In [71]: left
```

```
Out[71]:
```

	X	Y
0	bar	one
1	foo	one
2	foo	three
3	bar	three
4	foo	one
5	bar	one
6	bar	three
7	bar	three
8	bar	three
9	foo	three

```
In [72]: left.dtypes
```

```
Out[72]:
```

	X	Y
	category	
		object
		dtype: object

The right frame.

```
In [73]: right = pd.DataFrame(
```

```
.....:     {
.....:         "X": pd.Series(["foo", "bar"], dtype=CategoricalDtype(["foo", "bar"])),
.....:         "Z": [1, 2],
```

(continues on next page)

(continued from previous page)

...) }

In [74]: right

Out[74]:

	X	Z
0	foo	1
1	bar	2

In [75]: right.dtypes

Out[75]:

```
X      category  
Z      int64  
dtype: object
```

The merged result:

```
In [76]: result = pd.merge(left, right, how="outer")
```

In [77]: result

Out[77]:

	X	Y	Z
0	bar	one	2
1	bar	three	2
2	bar	one	2
3	bar	three	2
4	bar	three	2
5	bar	three	2
6	foo	one	1
7	foo	three	1
8	foo	one	1
9	foo	three	1

In [78]: result.dtypes

Out[78]:

```
X    category
Y    object
Z    int64
dtype: object
```

Note: The category dtypes must be *exactly* the same, meaning the same categories and the ordered attribute. Otherwise the result will coerce to the categories' dtype.

Note: Merging on category dtypes that are the same can be quite performant compared to object dtype merging.

Joining on index

`DataFrame.join()` is a convenient method for combining the columns of two potentially differently-indexed DataFrames into a single result DataFrame. Here is a very basic example:

```
In [79]: left = pd.DataFrame(
.....    {"A": ["A0", "A1", "A2"], "B": ["B0", "B1", "B2"]}, index=["K0", "K1", "K2"]
.....)
.....
```

```
In [80]: right = pd.DataFrame(
.....    {"C": ["C0", "C2", "C3"], "D": ["D0", "D2", "D3"]}, index=["K0", "K2", "K3"]
.....)
.....
```

```
In [81]: result = left.join(right)
```

left		right		Result						
		C	D	A	B	C	D			
K0	A0	B0	K0	C0	D0	K0	A0	B0	C0	D0
K1	A1	B1	K2	C2	D2	K1	A1	B1	NaN	NaN
K2	A2	B2	K3	C3	D3	K2	A2	B2	C2	D2

```
In [82]: result = left.join(right, how="outer")
```

left		right		Result						
		C	D	A	B	C	D			
K0	A0	B0	K0	C0	D0	K0	A0	B0	C0	D0
K1	A1	B1	K2	C2	D2	K1	A1	B1	NaN	NaN
K2	A2	B2	K3	C3	D3	K2	A2	B2	C2	D2
				K3	NaN	NaN	C3	D3		

The same as above, but with `how='inner'`.

```
In [83]: result = left.join(right, how="inner")
```

left		right		Result						
		C	D	A	B	C	D			
K0	A0	B0	K0	C0	D0	K0	A0	B0	C0	D0
K1	A1	B1	K2	C2	D2	K2	A2	B2	C2	D2
K2	A2	B2	K3	C3	D3	K2	A2	B2	C2	D2

The data alignment here is on the indexes (row labels). This same behavior can be achieved using `merge` plus additional arguments instructing it to use the indexes:

```
In [84]: result = pd.merge(left, right, left_index=True, right_index=True, how="outer")
```

left		right		Result			
		C	D	A	B	C	D
K0	A0	B0	D0	K0	A0	B0	D0
K1	A1	B1	D2	K1	A1	B1	NaN
K2	A2	B2	D3	K2	A2	B2	D2
				K3	NaN	NaN	D3

```
In [85]: result = pd.merge(left, right, left_index=True, right_index=True, how="inner")
```

left		right		Result			
		C	D	A	B	C	D
K0	A0	B0	D0	K0	A0	B0	D0
K1	A1	B1	D2	K2	A2	B2	D2
K2	A2	B2	D3				

Joining key columns on an index

`join()` takes an optional `on` argument which may be a column or multiple column names, which specifies that the passed DataFrame is to be aligned on that column in the DataFrame. These two function calls are completely equivalent:

```
left.join(right, on=key_or_keys)
pd.merge(
    left, right, left_on=key_or_keys, right_index=True, how="left", sort=False
)
```

Obviously you can choose whichever form you find more convenient. For many-to-one joins (where one of the DataFrame's is already indexed by the join key), using `join` may be more convenient. Here is a simple example:

```
In [86]: left = pd.DataFrame(
    ...:     {
    ...:         "A": ["A0", "A1", "A2", "A3"],
    ...:         "B": ["B0", "B1", "B2", "B3"],
    ...:         "key": ["K0", "K1", "K0", "K1"],
    ...:     }
    ...: )
```

```
In [87]: right = pd.DataFrame({"C": ["C0", "C1"], "D": ["D0", "D1"]}, index=["K0", "K1"])
```

```
In [88]: result = left.join(right, on="key")
```

left			right		Result							
	A	B	key		C	D	0	A0	B0	key0	C0	D0
0	A0	B0	K0		C0	D0	1	A1	B1	K1	C1	D1
1	A1	B1	K1		C1	D1	2	A2	B2	K0	C0	D0
2	A2	B2	K0				3	A3	B3	K1	C1	D1
3	A3	B3	K1									

```
In [89]: result = pd.merge(
.....:     left, right, left_on="key", right_index=True, how="left", sort=False
.....: )
.....:
```

left			right		Result							
	A	B	key		C	D	0	A0	B0	key0	C0	D0
0	A0	B0	K0		C0	D0	1	A1	B1	K1	C1	D1
1	A1	B1	K1		C1	D1	2	A2	B2	K0	C0	D0
2	A2	B2	K0				3	A3	B3	K1	C1	D1
3	A3	B3	K1									

the passed DataFrame must have a `MultiIndex`:

```
In [90]: left = pd.DataFrame(
.....:     {
.....:         "A": ["A0", "A1", "A2", "A3"],
.....:         "B": ["B0", "B1", "B2", "B3"],
.....:         "key1": ["K0", "K0", "K1", "K2"],
.....:         "key2": ["K0", "K1", "K0", "K1"]
.....:     }
.....: )
.....:
```

```
In [91]: index = pd.MultiIndex.from_tuples(
.....:     [("K0", "K0"), ("K1", "K0"), ("K2", "K0"), ("K2", "K1")]
.....: )
.....:
```

```
In [92]: right = pd.DataFrame(
.....:     {"C": ["C0", "C1", "C2", "C3"], "D": ["D0", "D1", "D2", "D3"]}, index=index
.....: )
.....:
```

To join on multiple keys,

Now this can be joined by passing the two key column names:

```
In [93]: result = left.join(right, on=["key1", "key2"])
```

left				right		Result							
	A	B	key1	key2		C	D	A	B	key1	key2	C	D
0	A0	B0	K0	K0	K0	C0	D0	A0	B0	K0	K0	C0	D0
1	A1	B1	K0	K1	K1	C1	D1	A1	B1	K0	K1	NaN	NaN
2	A2	B2	K1	K0	K2	C2	D2	A2	B2	K1	K0	C1	D1
3	A3	B3	K2	K1	K2	C3	D3	A3	B3	K2	K1	C3	D3

The

default for DataFrame.join is to perform a left join (essentially a “VLOOKUP” operation, for Excel users), which uses only the keys found in the calling DataFrame. Other join types, for example inner join, can be just as easily performed:

```
In [94]: result = left.join(right, on=["key1", "key2"], how="inner")
```

left				right		Result							
	A	B	key1	key2		C	D	A	B	key1	key2	C	D
0	A0	B0	K0	K0	K0	C0	D0	A0	B0	K0	K0	C0	D0
1	A1	B1	K0	K1	K1	C1	D1						
2	A2	B2	K1	K0	K2	C2	D2	A2	B2	K1	K0	C1	D1
3	A3	B3	K2	K1	K2	C3	D3	A3	B3	K2	K1	C3	D3

As you can see, this drops any rows where there was no match.

Joining a single Index to a MultiIndex

You can join a singly-indexed DataFrame with a level of a MultiIndexed DataFrame. The level will match on the name of the index of the singly-indexed frame against a level name of the MultiIndexed frame.

```
In [95]: left = pd.DataFrame(
.....:     {"A": ["A0", "A1", "A2"], "B": ["B0", "B1", "B2"]},
.....:     index=pd.Index(["K0", "K1", "K2"], name="key"),
.....: )
.....:
```

```
In [96]: index = pd.MultiIndex.from_tuples(
.....:     [("K0", "Y0"), ("K1", "Y1"), ("K2", "Y2"), ("K2", "Y3")],
.....:     names=["key", "Y"],
.....: )
.....:
```

```
In [97]: right = pd.DataFrame(
.....:     {"C": ["C0", "C1", "C2", "C3"], "D": ["D0", "D1", "D2", "D3"]},
.....:     index=index,
.....: )
.....:
```

```
In [98]: result = left.join(right, how="inner")
```

left		right		Result					
K0	A0	B0		C0	D0	A0	B0	C0	D0
K1	A1	B1		C1	D1	A1	B1	C1	D1
K2	A2	B2		C2	D2	A2	B2	C2	D2
				C3	D3	A2	B2	C3	D3

This is equivalent but less verbose and more memory efficient / faster than this.

```
In [99]: result = pd.merge(
.....    left.reset_index(), right.reset_index(), on=["key"], how="inner"
.....).set_index(["key", "Y"])
.....
```

left		right		Result					
K0	A0	B0		C0	D0	A0	B0	C0	D0
K1	A1	B1		C1	D1	A1	B1	C1	D1
K2	A2	B2		C2	D2	A2	B2	C2	D2
				C3	D3	A2	B2	C3	D3

Joining with two MultiIndexes

This is supported in a limited way, provided that the index for the right argument is completely used in the join, and is a subset of the indices in the left argument, as in this example:

```
In [100]: leftindex = pd.MultiIndex.from_product(
.....    [list("abc"), list("xy"), [1, 2]], names=["abc", "xy", "num"]
.....)
.....
```

```
In [101]: left = pd.DataFrame({"v1": range(12)}, index=leftindex)
```

```
In [102]: left
```

```
Out[102]:
      v1
abc xy num
a   x  1    0
     2    1
y   1    2
     2    3
b   x  1    4
     2    5
y   1    6
     2    7
```

(continues on next page)

(continued from previous page)

```
c   x  1     8
    2     9
y   1    10
    2    11

In [103]: rightindex = pd.MultiIndex.from_product(
.....:     [list("abc"), list("xy")], names=["abc", "xy"]
.....: )
.....:

In [104]: right = pd.DataFrame({"v2": [100 * i for i in range(1, 7)]}, index=rightindex)

In [105]: right
Out[105]:
      v2
abc xy
a   x  100
    y  200
b   x  300
    y  400
c   x  500
    y  600

In [106]: left.join(right, on=["abc", "xy"], how="inner")
Out[106]:
      v1    v2
abc xy num
a   x  1    0  100
    2    1  100
    y  1    2  200
    2    3  200
b   x  1    4  300
    2    5  300
    y  1    6  400
    2    7  400
c   x  1    8  500
    2    9  500
    y  1   10  600
    2   11  600
```

If that condition is not satisfied, a join with two multi-indexes can be done using the following code.

```
In [107]: leftindex = pd.MultiIndex.from_tuples(
.....:     [("K0", "X0"), ("K0", "X1"), ("K1", "X2")], names=["key", "X"]
.....: )
.....:

In [108]: left = pd.DataFrame(
.....:     {"A": ["A0", "A1", "A2"], "B": ["B0", "B1", "B2"]}, index=leftindex
.....: )
.....:
```

(continues on next page)

(continued from previous page)

```
In [109]: rightindex = pd.MultiIndex.from_tuples(
...:     [("K0", "Y0"), ("K1", "Y1"), ("K2", "Y2"), ("K2", "Y3")], names=["key", "Y"]
...: )
...:

In [110]: right = pd.DataFrame(
...:     {"C": ["C0", "C1", "C2", "C3"], "D": ["D0", "D1", "D2", "D3"]}, index=rightindex
...: )
...:

In [111]: result = pd.merge(
...:     left.reset_index(), right.reset_index(), on=["key"], how="inner"
...: ).set_index(["key", "X", "Y"])
...:
```

left		right		Result			
K0	X0	A	B	C0	D0	A	B
K0	X1	A1	B1	C1	D1	C	D
K1	X2	A2	B2	C2	D2		
K2				C3	D3		

Merging on a combination of columns and index levels

Strings passed as the `on`, `left_on`, and `right_on` parameters may refer to either column names or index level names. This enables merging DataFrame instances on a combination of index levels and columns without resetting indexes.

```
In [112]: left_index = pd.Index(["K0", "K0", "K1", "K2"], name="key1")

In [113]: left = pd.DataFrame(
...:     {
...:         "A": ["A0", "A1", "A2", "A3"],
...:         "B": ["B0", "B1", "B2", "B3"],
...:         "key2": ["K0", "K1", "K0", "K1"],
...:     },
...:     index=left_index,
...: )
...:

In [114]: right_index = pd.Index(["K0", "K1", "K2", "K2"], name="key1")

In [115]: right = pd.DataFrame(
...:     {
...:         "C": ["C0", "C1", "C2", "C3"],
...:         "D": ["D0", "D1", "D2", "D3"],
...:
```

(continues on next page)

(continued from previous page)

```
....:
    "key2": ["K0", "K0", "K0", "K1"],
....:
},
index=right_index,
....:
....:
```

In [116]: `result = left.merge(right, on=["key1", "key2"])`

left			right			Result					
	A	B	C	D	key2		A	B	key2	C	D
K0	A0	B0	C0	D0	K0	K0	A0	B0	K0	C0	D0
K0	A1	B1	C1	D1	K0	K1	A2	B2	K0	C1	D1
K1	A2	B2	C2	D2	K0	K2	A3	B3	K1	C3	D3
K2	A3	B3	C3	D3	K1	K2					

Note: When DataFrames are merged on a string that matches an index level in both frames, the index level is preserved as an index level in the resulting DataFrame.

Note: When DataFrames are merged using only some of the levels of a MultiIndex, the extra levels will be dropped from the resulting merge. In order to preserve those levels, use `reset_index` on those level names to move those levels to columns prior to doing the merge.

Note: If a string matches both a column name and an index level name, then a warning is issued and the column takes precedence. This will result in an ambiguity error in a future version.

Overlapping value columns

The merge `suffixes` argument takes a tuple of list of strings to append to overlapping column names in the input DataFrames to disambiguate the result columns:

In [117]: `left = pd.DataFrame({"k": ["K0", "K1", "K2"], "v": [1, 2, 3]})`

In [118]: `right = pd.DataFrame({"k": ["K0", "K0", "K3"], "v": [4, 5, 6]})`

In [119]: `result = pd.merge(left, right, on="k")`

left		right		Result		
	k	v		k	v_x	v_y
0	K0	1	0	K0	4	
1	K1	2	1	K0	5	
2	K2	3	2	K3	6	

```
In [120]: result = pd.merge(left, right, on="k", suffixes=("_l", "_r"))
```

left		right		Result		
	k	v		k	v_l	v_r
0	K0	1	0	K0	4	
1	K1	2	1	K0	5	
2	K2	3	2	K3	6	

`DataFrame.join()` has `lsuffix` and `rsuffix` arguments which behave similarly.

```
In [121]: left = left.set_index("k")
```

```
In [122]: right = right.set_index("k")
```

```
In [123]: result = left.join(right, lsuffix="_l", rsuffix="_r")
```

left		right		Result	
	v		v	v_l	v_r
K0	1	K0	4	K0	1 4.0
K1	2	K0	5	K0	1 5.0
K2	3	K3	6	K1	2 NaN

Joining multiple DataFrames

A list or tuple of DataFrames can also be passed to `join()` to join them together on their indexes.

```
In [124]: right2 = pd.DataFrame({"v": [7, 8, 9]}, index=["K1", "K1", "K2"])
```

```
In [125]: result = left.join([right, right2])
```

left	right	right2	Result
			v_x v_y v
K0 1	K0 4	K1 7	K0 1 4.0 NaN
K1 2	K0 5	K1 8	K0 1 5.0 NaN
K2 3	K3 6	K2 9	K1 2 NaN 7.0
			K1 2 NaN 8.0
			K2 3 NaN 9.0

Merging together values within Series or DataFrame columns

Another fairly common situation is to have two like-indexed (or similarly indexed) Series or DataFrame objects and wanting to “patch” values in one object from values for matching indices in the other. Here is an example:

```
In [126]: df1 = pd.DataFrame(
.....:     [[np.nan, 3.0, 5.0], [-4.6, np.nan, np.nan], [np.nan, 7.0, np.nan]]
.....: )
.....:
```

```
In [127]: df2 = pd.DataFrame([[-42.6, np.nan, -8.2], [-5.0, 1.6, 4]], index=[1, 2])
```

For this, use the `combine_first()` method:

```
In [128]: result = df1.combine_first(df2)
```

df1	df2	Result
		0 1 2
0 NaN 3.0 5.0	0 -42.6 NaN -8.2	0 NaN 3.0 5.0
1 -4.6 NaN NaN	1 -5.0 1.6 4.0	1 -4.6 NaN -8.2
2 NaN 7.0 NaN	2 -5.0 1.6 4.0	2 -5.0 7.0 4.0

Note that this method only takes values from the right DataFrame if they are missing in the left DataFrame. A related method, `update()`, alters non-NA values in place:

```
In [129]: df1.update(df2)
```

df1	df2	Result
		0 1 2
0 NaN 3.0 5.0	0 -42.6 NaN -8.2	0 NaN 3.0 5.0
1 -4.6 NaN NaN	1 -5.0 1.6 4.0	1 -42.6 NaN -8.2
2 NaN 7.0 NaN	2 -5.0 1.6 4.0	2 -5.0 1.6 4.0

2.7.3 Timeseries friendly merging

Merging ordered data

A `merge_ordered()` function allows combining time series and other ordered data. In particular it has an optional `fill_method` keyword to fill/interpolate missing data:

```
In [130]: left = pd.DataFrame(
    ....:     {"k": ["K0", "K1", "K1", "K2"], "lv": [1, 2, 3, 4], "s": ["a", "b", "c", "d"]
    ↵"]}
    ....: )
....:
```

```
In [131]: right = pd.DataFrame({"k": ["K1", "K2", "K4"], "rv": [1, 2, 3]})
```

```
In [132]: pd.merge_ordered(left, right, fill_method="ffill", left_by="s")
Out[132]:
```

	k	lv	s	rv
0	K0	1.0	a	NaN
1	K1	1.0	a	1.0
2	K2	1.0	a	2.0
3	K4	1.0	a	3.0
4	K1	2.0	b	1.0
5	K2	2.0	b	2.0
6	K4	2.0	b	3.0
7	K1	3.0	c	1.0
8	K2	3.0	c	2.0
9	K4	3.0	c	3.0
10	K1	NaN	d	1.0
11	K2	4.0	d	2.0
12	K4	4.0	d	3.0

Merging asof

A `merge_asof()` is similar to an ordered left-join except that we match on nearest key rather than equal keys. For each row in the `left` DataFrame, we select the last row in the `right` DataFrame whose `on` key is less than the left's key. Both DataFrames must be sorted by the key.

Optionally an asof merge can perform a group-wise merge. This matches the `by` key equally, in addition to the nearest match on the `on` key.

For example; we might have `trades` and `quotes` and we want to asof merge them.

```
In [133]: trades = pd.DataFrame(
    ....:     {
    ....:         "time": pd.to_datetime([
    ....:             "20160525 13:30:00.023",
    ....:             "20160525 13:30:00.038",
    ....:             "20160525 13:30:00.048",
    ....:             "20160525 13:30:00.048",
    ....:             "20160525 13:30:00.048",
    ....:         ])
    ....:     }
```

(continues on next page)

(continued from previous page)

```

        },
        "ticker": ["MSFT", "MSFT", "GOOG", "GOOG", "AAPL"],
        "price": [51.95, 51.95, 720.77, 720.92, 98.00],
        "quantity": [75, 155, 100, 100, 100],
    },
    columns=["time", "ticker", "price", "quantity"],
)
.....

```

In [134]: quotes = pd.DataFrame(
 {
 "time": pd.to_datetime([
 "20160525 13:30:00.023",
 "20160525 13:30:00.023",
 "20160525 13:30:00.030",

3	2016-05-25 13:30:00.041	MSFT	51.99	52.00
4	2016-05-25 13:30:00.048	GOOG	720.50	720.93
5	2016-05-25 13:30:00.049	AAPL	97.99	98.01
6	2016-05-25 13:30:00.072	GOOG	720.50	720.88
7	2016-05-25 13:30:00.075	MSFT	52.01	52.03

By default we are taking the asof of the quotes.

```
In [137]: pd.merge_asof(trades, quotes, on="time", by="ticker")
```

Out[137]:

	time	ticker	price	quantity	bid	ask
0	2016-05-25 13:30:00.023	MSFT	51.95	75	51.95	51.96
1	2016-05-25 13:30:00.038	MSFT	51.95	155	51.97	51.98
2	2016-05-25 13:30:00.048	GOOG	720.77	100	720.50	720.93
3	2016-05-25 13:30:00.048	GOOG	720.92	100	720.50	720.93
4	2016-05-25 13:30:00.048	AAPL	98.00	100	NaN	NaN

We only asof within 2ms between the quote time and the trade time.

```
In [138]: pd.merge_asof(trades, quotes, on="time", by="ticker", tolerance=pd.Timedelta(  
    ↪ "2ms"))
```

Out[138]:

	time	ticker	price	quantity	bid	ask
0	2016-05-25 13:30:00.023	MSFT	51.95	75	51.95	51.96
1	2016-05-25 13:30:00.038	MSFT	51.95	155	NaN	NaN
2	2016-05-25 13:30:00.048	GOOG	720.77	100	720.50	720.93
3	2016-05-25 13:30:00.048	GOOG	720.92	100	720.50	720.93
4	2016-05-25 13:30:00.048	AAPL	98.00	100	NaN	NaN

We only asof within 10ms between the quote time and the trade time and we exclude exact matches on time. Note that though we exclude the exact matches (of the quotes), prior quotes **do** propagate to that point in time.

```
In [139]: pd.merge_asof(  
    .....:     trades,  
    .....:     quotes,  
    .....:     on="time",  
    .....:     by="ticker",  
    .....:     tolerance=pd.Timedelta("10ms"),  
    .....:     allow_exact_matches=False,  
    .....: )  
    .....:
```

Out[139]:

	time	ticker	price	quantity	bid	ask
0	2016-05-25 13:30:00.023	MSFT	51.95	75	NaN	NaN
1	2016-05-25 13:30:00.038	MSFT	51.95	155	51.97	51.98
2	2016-05-25 13:30:00.048	GOOG	720.77	100	NaN	NaN
3	2016-05-25 13:30:00.048	GOOG	720.92	100	NaN	NaN
4	2016-05-25 13:30:00.048	AAPL	98.00	100	NaN	NaN

2.7.4 Comparing objects

The `compare()` and `compare()` methods allow you to compare two DataFrame or Series, respectively, and summarize their differences.

This feature was added in [V1.1.0](#).

For example, you might want to compare two DataFrame and stack their differences side by side.

```
In [140]: df = pd.DataFrame(  
    .....:     {
```

(continues on next page)

(continued from previous page)

```
....:     "col1": ["a", "a", "b", "b", "a"],
....:     "col2": [1.0, 2.0, 3.0, np.nan, 5.0],
....:     "col3": [1.0, 2.0, 3.0, 4.0, 5.0],
....:   },
....:   columns=["col1", "col2", "col3"],
....: )
....:
```

In [141]: df**Out[141]:**

	col1	col2	col3
0	a	1.0	1.0
1	a	2.0	2.0
2	b	3.0	3.0
3	b	NaN	4.0
4	a	5.0	5.0

In [142]: df2 = df.copy()**In [143]:** df2.loc[0, "col1"] = "c"**In [144]:** df2.loc[2, "col3"] = 4.0**In [145]:** df2**Out[145]:**

	col1	col2	col3
0	c	1.0	1.0
1	a	2.0	2.0
2	b	3.0	4.0
3	b	NaN	4.0
4	a	5.0	5.0

In [146]: df.compare(df2)**Out[146]:**

	col1	col3		
	self	other	self	other
0	a	c	NaN	NaN
2	NaN	NaN	3.0	4.0

By default, if two corresponding values are equal, they will be shown as NaN. Furthermore, if all values in an entire row / column, the row / column will be omitted from the result. The remaining differences will be aligned on columns.

If you wish, you may choose to stack the differences on rows.

In [147]: df.compare(df2, align_axis=0)**Out[147]:**

	col1	col3	
0	self	a	NaN
	other	c	NaN
2	self	NaN	3.0
	other	NaN	4.0

If you wish to keep all original rows and columns, set `keep_shape` argument to True.

```
In [148]: df.compare(df2, keep_shape=True)
```

Out[148]:

	col1	col2	col3			
	self	other	self	other	self	other
0	a	c	NaN	NaN	NaN	NaN
1	NaN	NaN	NaN	NaN	NaN	NaN
2	NaN	NaN	NaN	NaN	3.0	4.0
3	NaN	NaN	NaN	NaN	NaN	NaN
4	NaN	NaN	NaN	NaN	NaN	NaN

You may also keep all the original values even if they are equal.

```
In [149]: df.compare(df2, keep_shape=True, keep_equal=True)
```

Out[149]:

	col1	col2	col3			
	self	other	self	other	self	other
0	a	c	1.0	1.0	1.0	1.0
1	a	a	2.0	2.0	2.0	2.0
2	b	b	3.0	3.0	3.0	4.0
3	b	b	NaN	NaN	4.0	4.0
4	a	a	5.0	5.0	5.0	5.0

2.8 Reshaping and pivot tables

2.8.1 Reshaping by pivoting DataFrame objects

Pivot

df

```
df.pivot(index='foo',
         columns='bar',
         values='baz')
```

	foo	bar	baz	zoo
0	one	A	1	x
1	one	B	2	y
2	one	C	3	z
3	two	A	4	q
4	two	B	5	w
5	two	C	6	t

bar	A	B	C
foo			
one	1	2	3
two	4	5	6

Data is often stored in so-called “stacked” or “record” format:

```
In [1]: import pandas._testing as tm

In [2]: def unpivot(frame):
...:     N, K = frame.shape
...:     data = {
...:         "value": frame.to_numpy().ravel("F"),
...:         "variable": np.asarray(frame.columns).repeat(N),
...:         "date": np.tile(np.asarray(frame.index), K),
...:     }
...:     return pd.DataFrame(data, columns=["date", "variable", "value"])
...:

In [3]: df = unpivot(tm.makeTimeDataFrame(3))

In [4]: df
Out[4]:
      date variable    value
0 2000-01-03        A  0.469112
1 2000-01-04        A -0.282863
2 2000-01-05        A -1.509059
3 2000-01-03        B -1.135632
4 2000-01-04        B  1.212112
5 2000-01-05        B -0.173215
6 2000-01-03        C  0.119209
7 2000-01-04        C -1.044236
8 2000-01-05        C -0.861849
9 2000-01-03        D -2.104569
10 2000-01-04       D -0.494929
11 2000-01-05       D  1.071804
```

To select out everything for variable A we could do:

```
In [5]: filtered = df[df["variable"] == "A"]

In [6]: filtered
Out[6]:
      date variable    value
0 2000-01-03        A  0.469112
1 2000-01-04        A -0.282863
2 2000-01-05        A -1.509059
```

But suppose we wish to do time series operations with the variables. A better representation would be where the `columns` are the unique variables and an `index` of dates identifies individual observations. To reshape the data into this form, we use the `DataFrame.pivot()` method (also implemented as a top level function `pivot()`):

```
In [7]: pivoted = df.pivot(index="date", columns="variable", values="value")

In [8]: pivoted
Out[8]:
variable          A          B          C          D
date
2000-01-03  0.469112 -1.135632  0.119209 -2.104569
2000-01-04 -0.282863  1.212112 -1.044236 -0.494929
```

(continues on next page)

(continued from previous page)

2000-01-05 -1.509059 -0.173215 -0.861849 1.071804

If the `values` argument is omitted, and the input `DataFrame` has more than one column of values which are not used as column or index inputs to `pivot()`, then the resulting “pivoted” `DataFrame` will have *hierarchical columns* whose topmost level indicates the respective value column:

```
In [9]: df["value2"] = df["value"] * 2
```

```
In [10]: pivoted = df.pivot(index="date", columns="variable")
```

```
In [11]: pivoted
```

```
Out[11]:
```

	value				value2			
variable	A	B	C	D	A	B	C	
date								
2000-01-03	0.469112	-1.135632	0.119209	-2.104569	0.938225	-2.271265	0.238417	-4.209138
2000-01-04	-0.282863	1.212112	-1.044236	-0.494929	-0.565727	2.424224	-2.088472	-0.989859
2000-01-05	-1.509059	-0.173215	-0.861849	1.071804	-3.018117	-0.346429	-1.723698	2.143608

You can then select subsets from the pivoted `DataFrame`:

```
In [12]: pivoted["value2"]
```

```
Out[12]:
```

variable	A	B	C	D
date				
2000-01-03	0.938225	-2.271265	0.238417	-4.209138
2000-01-04	-0.565727	2.424224	-2.088472	-0.989859
2000-01-05	-3.018117	-0.346429	-1.723698	2.143608

Note that this returns a view on the underlying data in the case where the data are homogeneously-typed.

Note: `pivot()` will error with a `ValueError: Index contains duplicate entries, cannot reshape` if the index/column pair is not unique. In this case, consider using `pivot_table()` which is a generalization of pivot that can handle duplicate values for one index/column pair.

2.8.2 Reshaping by stacking and unstacking

Stack

Closely related to the `pivot()` method are the related `stack()` and `unstack()` methods available on `Series` and `DataFrame`. These methods are designed to work together with `MultiIndex` objects (see the section on `hierarchical indexing`). Here are essentially what these methods do:

- `stack()`: “pivot” a level of the (possibly hierarchical) column labels, returning a `DataFrame` with an index with a new inner-most level of row labels.
- `unstack()`: (inverse operation of `stack()`) “pivot” a level of the (possibly hierarchical) row index to the column axis, producing a reshaped `DataFrame` with a new inner-most level of column labels.

Unstack

The clearest way to explain is by example. Let's take a prior example data set from the hierarchical indexing section:

```
In [13]: tuples = list(
...:     zip(
...:         *[[
...:             ["bar", "bar", "baz", "baz", "foo", "foo", "qux", "qux"],
...:             ["one", "two", "one", "two", "one", "two", "one", "two"]
...:         ],
...:         []
...:     )
...: )

In [14]: index = pd.MultiIndex.from_tuples(tuples, names=["first", "second"])

In [15]: df = pd.DataFrame(np.random.randn(8, 2), index=index, columns=["A", "B"])

In [16]: df2 = df[:4]

In [17]: df2
Out[17]:
          A          B
first second
bar    one      0.721555 -0.706771
       two     -1.039575  0.271860
baz    one     -0.424972  0.567020
       two      0.276232 -1.087401
```

The `stack()` function “compresses” a level in the `DataFrame` columns to produce either:

- A `Series`, in the case of a simple column `Index`.

- A `DataFrame`, in the case of a `MultiIndex` in the columns.

If the columns have a `MultiIndex`, you can choose which level to stack. The stacked level becomes the new lowest level in a `MultiIndex` on the columns:

```
In [18]: stacked = df2.stack()
```

```
In [19]: stacked
```

```
Out[19]:
```

```
first  second
bar    one      A    0.721555
                  B   -0.706771
                 two     A   -1.039575
                  B    0.271860
baz    one      A   -0.424972
                  B    0.567020
                 two     A    0.276232
                  B   -1.087401
dtype: float64
```

With a “stacked” `DataFrame` or `Series` (having a `MultiIndex` as the `index`), the inverse operation of `stack()` is `unstack()`, which by default unstacks the `last level`:

```
In [20]: stacked.unstack()
```

```
Out[20]:
```

```
          A         B
first  second
bar    one    0.721555 -0.706771
                 two   -1.039575  0.271860
baz    one   -0.424972  0.567020
                 two    0.276232 -1.087401
```

```
In [21]: stacked.unstack(1)
```

```
Out[21]:
```

```
second      one      two
first
bar    A  0.721555 -1.039575
                  B -0.706771  0.271860
baz    A -0.424972  0.276232
                  B  0.567020 -1.087401
```

```
In [22]: stacked.unstack(0)
```

```
Out[22]:
```

```
first      bar      baz
second
one    A  0.721555 -0.424972
                  B -0.706771  0.567020
two     A -1.039575  0.276232
                  B  0.271860 -1.087401
```

Unstack(1)

If the indexes have names, you can use the level names instead of specifying the level numbers:

```
In [23]: stacked.unstack("second")
Out[23]:
second      one      two
first
bar    A  0.721555 -1.039575
       B -0.706771  0.271860
baz    A -0.424972  0.276232
       B  0.567020 -1.087401
```

Unstack(0)

Notice that the `stack()` and `unstack()` methods implicitly sort the index levels involved. Hence a call to `stack()` and then `unstack()`, or vice versa, will result in a **sorted** copy of the original `DataFrame` or `Series`:

```
In [24]: index = pd.MultiIndex.from_product([[2, 1], ["a", "b"]])

In [25]: df = pd.DataFrame(np.random.randn(4), index=index, columns=["A"])

In [26]: df
Out[26]:
      A
2 a -0.370647
    b -1.157892
1 a -1.344312
    b  0.844885

In [27]: all(df.unstack().stack() == df.sort_index())
Out[27]: True
```

The above code will raise a `TypeError` if the call to `sort_index()` is removed.

Multiple levels

You may also stack or unstack more than one level at a time by passing a list of levels, in which case the end result is as if each level in the list were processed individually.

```
In [28]: columns = pd.MultiIndex.from_tuples(
.....:     [
.....:         ("A", "cat", "long"),
.....:         ("B", "cat", "long"),
.....:         ("A", "dog", "short"),
.....:     ]
```

(continues on next page)

(continued from previous page)

```

....:         ("B", "dog", "short"),
....:     ],
....:     names=["exp", "animal", "hair_length"],
....: )
....:

```

In [29]: `df = pd.DataFrame(np.random.randn(4, 4), columns=columns)`

In [30]: `df`

Out[30]:

		A	B	A	B
exp					
animal		cat	cat	dog	dog
hair_length		long	long	short	short
0		1.075770	-0.109050	1.643563	-1.469388
1		0.357021	-0.674600	-1.776904	-0.968914
2		-1.294524	0.413738	0.276662	-0.472035
3		-0.013960	-0.362543	-0.006154	-0.923061

In [31]: `df.stack(level=["animal", "hair_length"])`

Out[31]:

			A	B
exp				
	animal	hair_length		
0	cat	long	1.075770	-0.109050
	dog	short	1.643563	-1.469388
1	cat	long	0.357021	-0.674600
	dog	short	-1.776904	-0.968914
2	cat	long	-1.294524	0.413738
	dog	short	0.276662	-0.472035
3	cat	long	-0.013960	-0.362543
	dog	short	-0.006154	-0.923061

The list of levels can contain either level names or level numbers (but not a mixture of the two).

```
# df.stack(level=['animal', 'hair_length'])
# from above is equivalent to:
```

In [32]: `df.stack(level=[1, 2])`

Out[32]:

			A	B
exp				
	animal	hair_length		
0	cat	long	1.075770	-0.109050
	dog	short	1.643563	-1.469388
1	cat	long	0.357021	-0.674600
	dog	short	-1.776904	-0.968914
2	cat	long	-1.294524	0.413738
	dog	short	0.276662	-0.472035
3	cat	long	-0.013960	-0.362543
	dog	short	-0.006154	-0.923061

Missing data

These functions are intelligent about handling missing data and do not expect each subgroup within the hierarchical index to have the same set of labels. They also can handle the index being unsorted (but you can make it sorted by calling `sort_index()`, of course). Here is a more complex example:

```
In [33]: columns = pd.MultiIndex.from_tuples([
....:     [
....:         ("A", "cat"),
....:         ("B", "dog"),
....:         ("B", "cat"),
....:         ("A", "dog"),
....:     ],
....:     names=["exp", "animal"],
....: )
....:

In [34]: index = pd.MultiIndex.from_product(
....:     [("bar", "baz", "foo", "qux"), ("one", "two")], names=["first", "second"]
....: )
....:

In [35]: df = pd.DataFrame(np.random.randn(8, 4), index=index, columns=columns)

In [36]: df2 = df.iloc[[0, 1, 2, 4, 5, 7]]

In [37]: df2
Out[37]:
exp           A           B           A
animal       cat        dog        cat        dog
first second
bar   one    0.895717  0.805244 -1.206412  2.565646
      two    1.431256  1.340309 -1.170299 -0.226169
baz   one    0.410835  0.813850  0.132003 -0.827317
foo   one   -1.413681  1.607920  1.024180  0.569605
      two    0.875906 -2.211372  0.974466 -2.006747
qux   two   -1.226825  0.769804 -1.281247 -0.727707
```

As mentioned above, `stack()` can be called with a `level` argument to select which level in the columns to stack:

```
In [38]: df2.stack("exp")
Out[38]:
animal           cat        dog
first second exp
bar   one    A    0.895717  2.565646
      two    B   -1.206412  0.805244
baz   one    A    0.410835 -0.827317
      two    B    0.132003  0.813850
foo   one    A   -1.413681  0.569605
      two    B    1.024180  1.607920
qux   two    A    0.875906 -2.006747
      two    B    0.974466 -2.211372
```

(continues on next page)

(continued from previous page)

```
qux    two     A   -1.226825 -0.727707
          B   -1.281247  0.769804
```

In [39]: df2.stack("animal")

Out[39]:

			A	B
exp	first	second	animal	
	bar	one	cat	0.895717
		dog	2.565646	0.805244
baz	two	cat	1.431256	-1.170299
		dog	-0.226169	1.340309
foo	one	cat	0.410835	0.132003
		dog	-0.827317	0.813850
qux	one	cat	-1.413681	1.024180
		dog	0.569605	1.607920
	two	cat	0.875906	0.974466
		dog	-2.006747	-2.211372
qux	two	cat	-1.226825	-1.281247
		dog	-0.727707	0.769804

Unstacking can result in missing values if subgroups do not have the same set of labels. By default, missing values will be replaced with the default fill value for that data type, NaN for float, NaT for datetimelike, etc. For integer types, by default data will converted to float and missing values will be set to NaN.

In [40]: df3 = df.iloc[[0, 1, 4, 7], [1, 2]]

In [41]: df3

Out[41]:

		B	
exp	animal	dog	cat
	first	second	
bar	one	0.805244	-1.206412
	two	1.340309	-1.170299
foo	one	1.607920	1.024180
qux	two	0.769804	-1.281247

In [42]: df3.unstack()

Out[42]:

		B			
exp	animal	dog		cat	
	second	one	two	one	two
first					
bar	0.805244	1.340309	-1.206412	-1.170299	
foo	1.607920		NaN	1.024180	NaN
qux		NaN	0.769804		NaN
				-1.281247	

Alternatively, unstack takes an optional `fill_value` argument, for specifying the value of missing data.

In [43]: df3.unstack(fill_value=-1e9)

Out[43]:

		B			
exp	animal	dog		cat	
	second	one	two	one	two
first					
bar	0.805244	1.340309	-1.206412	-1.170299	
foo	1.607920		NaN	1.024180	NaN
qux		NaN	0.769804		NaN
				-1.281247	

(continues on next page)

(continued from previous page)

	one	two	one	two
second				
first				
bar	8.052440e-01	1.340309e+00	-1.206412e+00	-1.170299e+00
foo	1.607920e+00	-1.000000e+09	1.024180e+00	-1.000000e+09
qux	-1.000000e+09	7.698036e-01	-1.000000e+09	-1.281247e+00

With a MultiIndex

Unstacking when the columns are a *MultiIndex* is also careful about doing the right thing:

In [44]: `df[:3].unstack(0)`

Out[44]:

	A		B		cat		dog		A
exp	cat	baz	dog	bar	baz	bar	baz	bar	baz
animal									
first	bar	baz	bar	baz	bar	baz	bar	baz	
second									
one	0.895717	0.410835	0.805244	0.81385	-1.206412	0.132003	2.565646	-0.827317	
two	1.431256	NaN	1.340309	NaN	-1.170299	NaN	-0.226169	NaN	

In [45]: `df2.unstack(1)`

Out[45]:

	A		B		cat		dog		A
exp	cat		dog						
animal	one	two	one	two	one	two	one	two	
second									
first									
bar	0.895717	1.431256	0.805244	1.340309	-1.206412	-1.170299	2.565646	-0.226169	
baz	0.410835	NaN	0.813850	NaN	0.132003	NaN	-0.827317	NaN	
foo	-1.413681	0.875906	1.607920	-2.211372	1.024180	0.974466	0.569605	-2.006747	
qux	NaN	-1.226825	NaN	0.769804	NaN	-1.281247	NaN	-0.727707	

2.8.3 Reshaping by melt

Melt

The top-level `melt()` function and the corresponding `DataFrame.melt()` are useful to massage a `DataFrame` into a format where one or more columns are *identifier variables*, while all other columns, considered *measured variables*, are “unpivoted” to the row axis, leaving just two non-identifier columns, “variable” and “value”. The names of those columns can be customized by supplying the `var_name` and `value_name` parameters.

For instance,

```
In [46]: cheese = pd.DataFrame(
    ....:     {
    ....:         "first": ["John", "Mary"],
    ....:         "last": ["Doe", "Bo"],
    ....:         "height": [5.5, 6.0],
    ....:         "weight": [130, 150],
    ....:     }
    ....: )
```

```
In [47]: cheese
Out[47]:
   first last  height  weight
0  John  Doe      5.5     130
1  Mary   Bo      6.0     150
```

```
In [48]: cheese.melt(id_vars=["first", "last"])
Out[48]:
   first last variable  value
0  John  Doe    height    5.5
1  Mary   Bo    height    6.0
2  John  Doe   weight  130.0
3  Mary   Bo   weight  150.0
```

(continues on next page)

(continued from previous page)

```
In [49]: cheese.melt(id_vars=["first", "last"], var_name="quantity")
Out[49]:
```

	first	last	quantity	value
0	John	Doe	height	5.5
1	Mary	Bo	height	6.0
2	John	Doe	weight	130.0
3	Mary	Bo	weight	150.0

When transforming a DataFrame using `melt()`, the index will be ignored. The original index values can be kept around by setting the `ignore_index` parameter to `False` (default is `True`). This will however duplicate them.

New in version 1.1.0.

```
In [50]: index = pd.MultiIndex.from_tuples([('person', 'A'), ('person', 'B')])
```

```
In [51]: cheese = pd.DataFrame(
```

```
.....:     {
.....:         "first": ["John", "Mary"],
.....:         "last": ["Doe", "Bo"],
.....:         "height": [5.5, 6.0],
.....:         "weight": [130, 150],
.....:     },
.....:     index=index,
.....: )
```

```
In [52]: cheese
```

```
Out[52]:
```

	first	last	height	weight
person A	John	Doe	5.5	130
	Mary	Bo	6.0	150

```
In [53]: cheese.melt(id_vars=["first", "last"])
```

```
Out[53]:
```

	first	last	variable	value
0	John	Doe	height	5.5
1	Mary	Bo	height	6.0
2	John	Doe	weight	130.0
3	Mary	Bo	weight	150.0

```
In [54]: cheese.melt(id_vars=["first", "last"], ignore_index=False)
```

```
Out[54]:
```

	first	last	variable	value
person A	John	Doe	height	5.5
	Mary	Bo	height	6.0
A	John	Doe	weight	130.0
B	Mary	Bo	weight	150.0

Another way to transform is to use the `wide_to_long()` panel data convenience function. It is less flexible than `melt()`, but more user-friendly.

```
In [55]: dft = pd.DataFrame(
...:     {
...:         "A1970": {0: "a", 1: "b", 2: "c"}, 
...:         "A1980": {0: "d", 1: "e", 2: "f"}, 
...:         "B1970": {0: 2.5, 1: 1.2, 2: 0.7}, 
...:         "B1980": {0: 3.2, 1: 1.3, 2: 0.1}, 
...:         "X": dict(zip(range(3), np.random.randn(3))), 
...:     }
...: )
...:

In [56]: dft["id"] = dft.index

In [57]: dft
Out[57]:
   A1970  A1980  B1970  B1980      X  id
0      a      d    2.5    3.2 -0.121306  0
1      b      e    1.2    1.3 -0.097883  1
2      c      f    0.7    0.1  0.695775  2

In [58]: pd.wide_to_long(dft, ["A", "B"], i="id", j="year")
Out[58]:
      X  A      B
id year
0  1970  -0.121306  a  2.5
1  1970  -0.097883  b  1.2
2  1970   0.695775  c  0.7
0  1980  -0.121306  d  3.2
1  1980  -0.097883  e  1.3
2  1980   0.695775  f  0.1
```

2.8.4 Combining with stats and GroupBy

It should be no shock that combining `pivot()` / `stack()` / `unstack()` with GroupBy and the basic Series and DataFrame statistical functions can produce some very expressive and fast data manipulations.

```
In [59]: df
Out[59]:
exp
animal          A          B          A
           cat      dog      cat      dog
first second
bar   one   0.895717  0.805244 -1.206412  2.565646
       two   1.431256  1.340309 -1.170299 -0.226169
baz   one   0.410835  0.813850  0.132003 -0.827317
       two  -0.076467 -1.187678  1.130127 -1.436737
foo   one  -1.413681  1.607920  1.024180  0.569605
       two   0.875906 -2.211372  0.974466 -2.006747
qux   one  -0.410001 -0.078638  0.545952 -1.219217
       two  -1.226825  0.769804 -1.281247 -0.727707
```

```
In [60]: df.stack().mean(1).unstack()
```

(continues on next page)

(continued from previous page)

Out[60]:

```
animal          cat      dog
first second
bar   one    -0.155347  1.685445
      two     0.130479  0.557070
baz   one     0.271419 -0.006733
      two     0.526830 -1.312207

one     0.071448  0.455513
two    -0.424186 -0.204486
```

In [63]: df.mean().unstack(0)**Out[63]:**

```
exp          A      B
animal
cat     0.060843  0.018596
dog    -0.413580  0.232430
```

2.8.5 Pivot tables

While `pivot()` provides general purpose pivoting with various data types (strings, numerics, etc.), pandas also provides `pivot_table()` for pivoting with aggregation of numeric data.

The function `pivot_table()` can be used to create spreadsheet-style pivot tables. See the *cookbook* for some advanced strategies.

It takes a number of arguments:

- `data`: a DataFrame object.
- `values`: a column or a list of columns to aggregate.

- `index`: a column, Grouper, array which has the same length as data, or list of them. Keys to group by on the pivot table index. If an array is passed, it is being used as the same manner as column values.
- `columns`: a column, Grouper, array which has the same length as data, or list of them. Keys to group by on the pivot table column. If an array is passed, it is being used as the same manner as column values.
- `aggfunc`: function to use for aggregation, defaulting to `numpy.mean`.

Consider a data set like this:

```
In [64]: import datetime

In [65]: df = pd.DataFrame(
...:     {
...:         "A": ["one", "one", "two", "three"] * 6,
...:         "B": ["A", "B", "C"] * 8,
...:         "C": ["foo", "foo", "foo", "bar", "bar", "bar"] * 4,
...:         "D": np.random.randn(24),
...:         "E": np.random.randn(24),
...:         "F": [datetime.datetime(2013, i, 1) for i in range(1, 13)]
...:             + [datetime.datetime(2013, i, 15) for i in range(1, 13)],
...:     }
...: )
...:

In [66]: df
Out[66]:
   A    B    C          D          E          F
0  one   A  foo  0.341734 -0.317441 2013-01-01
1  one   B  foo  0.959726 -1.236269 2013-02-01
2  two   C  foo -1.110336  0.896171 2013-03-01
3  three  A  bar -0.619976 -0.487602 2013-04-01
4  one   B  bar  0.149748 -0.082240 2013-05-01
..   ...  ...  ...
19 three  B  foo  0.690579 -2.213588 2013-08-15
20  one  C  foo  0.995761  1.063327 2013-09-15
21  one  A  bar  2.396780  1.266143 2013-10-15
22  two  B  bar  0.014871  0.299368 2013-11-15
23 three  C  bar  3.357427 -0.863838 2013-12-15

[24 rows x 6 columns]
```

We can produce pivot tables from this data very easily:

```
In [67]: pd.pivot_table(df, values="D", index=["A", "B"], columns=["C"])
Out[67]:
C              bar        foo
A
one
  A  1.120915 -0.514058
  B -0.338421  0.002759
  C -0.538846  0.699535
three
  A -1.181568      NaN
  B      NaN  0.433512
  C  0.588783      NaN
two
  A      NaN  1.000985
```

(continues on next page)

(continued from previous page)

```
B  0.158248      NaN
C      NaN  0.176180
```

In [68]: pd.pivot_table(df, values="D", index=["B"], columns=["A", "C"], aggfunc=np.sum)
Out[68]:

	A	one	three	two		
C	bar	foo	bar	foo		
B						
A	2.241830	-1.028115	-2.363137	NaN	NaN	2.001971
B	-0.676843	0.005518	NaN	0.867024	0.316495	NaN
C	-1.077692	1.399070	1.177566	NaN	NaN	0.352360

In [69]: pd.pivot_table(
.....: df, values=["D", "E"],
.....: index=["B"],
.....: columns=["A", "C"],
.....: aggfunc=np.sum,
.....:)
.....:

Out[69]:

	D	E							
	one	two	one						
	three	two	two						
C	bar	foo	bar	foo					
	bar	foo	bar	foo					
B									
A	2.241830	-1.028115	-2.363137	NaN	NaN	2.001971	2.786113	-0.043211	1.
	922577	NaN	NaN	0.128491					
B	-0.676843	0.005518	NaN	0.867024	0.316495	NaN	1.368280	-1.103384	
	NaN	-2.128743	-0.194294	NaN					
C	-1.077692	1.399070	1.177566	NaN	NaN	0.352360	-1.976883	1.495717	-0.
	263660	NaN	NaN	0.872482					

The result object is a `DataFrame` having potentially hierarchical indexes on the rows and columns. If the `values` column name is not given, the pivot table will include all of the data that can be aggregated in an additional level of hierarchy in the columns:

In [70]: pd.pivot_table(df, index=["A", "B"], columns=["C"])
Out[70]:

	D	E		
C	bar	foo	bar	foo
A	B			
one	A 1.120915 -0.514058 1.393057 -0.021605			
	B -0.338421 0.002759 0.684140 -0.551692			
	C -0.538846 0.699535 -0.988442 0.747859			
three	A -1.181568 NaN 0.961289 NaN			
	B NaN 0.433512 NaN -1.064372			
	C 0.588783 NaN -0.131830 NaN			
two	A NaN 1.000985 NaN 0.064245			
	B 0.158248 NaN -0.097147 NaN			

(continues on next page)

(continued from previous page)

C	NaN	0.176180	NaN	0.436241
---	-----	----------	-----	----------

Also, you can use `Grouper` for `index` and `columns` keywords. For detail of `Grouper`, see [Grouping with a Grouper specification](#).

```
In [71]: pd.pivot_table(df, values="D", index=pd.Grouper(freq="M", key="F"), columns="C")
Out[71]:
C          bar      foo
F
2013-01-31    NaN -0.514058
2013-02-28    NaN  0.002759
2013-03-31    NaN  0.176180
2013-04-30 -1.181568      NaN
2013-05-31 -0.338421      NaN
2013-06-30 -0.538846      NaN
2013-07-31     NaN  1.000985
2013-08-31     NaN  0.433512
2013-09-30     NaN  0.699535
2013-10-31  1.120915      NaN
2013-11-30  0.158248      NaN
2013-12-31  0.588783      NaN
```

You can render a nice output of the table omitting the missing values by calling `to_string()` if you wish:

```
In [72]: table = pd.pivot_table(df, index=["A", "B"], columns=["C"])
```

```
In [73]: print(table.to_string(na_rep=""))
          D           E
          bar      foo    bar      foo
C
A   B
one  A  1.120915 -0.514058  1.393057 -0.021605
     B -0.338421  0.002759  0.684140 -0.551692
     C -0.538846  0.699535 -0.988442  0.747859
three A -1.181568          0.961289
      B          0.433512         -1.064372
      C  0.588783          -0.131830
two   A          1.000985          0.064245
      B  0.158248          -0.097147
      C  0.176180          0.436241
```

Note that `pivot_table()` is also available as an instance method on `DataFrame`, i.e.

`DataFrame.`

`pivot_table()`.

Adding margins

If you pass `margins=True` to `pivot_table()`, special All columns and rows will be added with partial group aggregates across the categories on the rows and columns:

```
In [74]: table = df.pivot_table(index=["A", "B"], columns="C", margins=True, aggfunc=np.std)
```

```
In [75]: table
```

```
Out[75]:
```

		D		E				
C		bar	foo	All	bar	foo	All	
A	B							
one	A	1.804346	1.210272	1.569879	0.179483	0.418374	0.858005	
	B	0.690376	1.353355	0.898998	1.083825	0.968138	1.101401	
	C	0.273641	0.418926	0.771139	1.689271	0.446140	1.422136	
three	A	0.794212		NaN	0.794212	2.049040	NaN	2.049040
	B	NaN	0.363548	0.363548		1.625237	1.625237	
	C	3.915454		NaN	3.915454	1.035215	NaN	1.035215
two	A	NaN	0.442998	0.442998		0.447104	0.447104	
	B	0.202765		NaN	0.202765	0.560757	NaN	0.560757
	C	NaN	1.819408	1.819408		0.650439	0.650439	
All		1.556686	0.952552	1.246608	1.250924	0.899904	1.059389	

Additionally, you can call `DataFrame.stack()` to display a pivoted DataFrame as having a multi-level index:

```
In [76]: table.stack()
```

```
Out[76]:
```

		D	E
A	B	C	
one	A	All	1.569879 0.858005
		bar	1.804346 0.179483
		foo	1.210272 0.418374
	B	All	0.898998 1.101401
		bar	0.690376 1.083825
...
two	C	All	1.819408 0.650439
		foo	1.819408 0.650439
All		All	1.246608 1.059389
		bar	1.556686 1.250924
		foo	0.952552 0.899904

```
[24 rows x 2 columns]
```

2.8.6 Cross tabulations

Use `crosstab()` to compute a cross-tabulation of two (or more) factors. By default `crosstab()` computes a frequency table of the factors unless an array of values and an aggregation function are passed.

It takes a number of arguments

- `index`: array-like, values to group by in the rows.
- `columns`: array-like, values to group by in the columns.
- `values`: array-like, optional, array of values to aggregate according to the factors.
- `aggfunc`: function, optional, If no values array is passed, computes a frequency table.
- `rownames`: sequence, default `None`, must match number of row arrays passed.
- `colnames`: sequence, default `None`, if passed, must match number of column arrays passed.
- `margins`: boolean, default `False`, Add row/column margins (subtotals)
- `normalize`: boolean, {‘all’, ‘index’, ‘columns’}, or {0,1}, default `False`. Normalize by dividing all values by the sum of values.

Any `Series` passed will have their name attributes used unless row or column names for the cross-tabulation are specified

For example:

```
In [77]: foo, bar, dull, shiny, one, two = "foo", "bar", "dull", "shiny", "one", "two"
In [78]: a = np.array([foo, foo, bar, bar, foo, foo], dtype=object)
In [79]: b = np.array([one, one, two, one, two, one], dtype=object)
In [80]: c = np.array([dull, dull, shiny, dull, dull, shiny], dtype=object)
In [81]: pd.crosstab(a, [b, c], rownames=[“a”], colnames=[“b”, “c”])
Out[81]:
b      one      two
c  dull shiny dull shiny
a
bar    1      0      0      1
foo    2      1      1      0
```

If `crosstab()` receives only two Series, it will provide a frequency table.

```
In [82]: df = pd.DataFrame(
.....:     {"A": [1, 2, 2, 2], "B": [3, 3, 4, 4], "C": [1, 1, np.nan, 1]}
.....:
.....:
In [83]: df
Out[83]:
   A   B   C
0  1  3  1.0
1  2  3  1.0
2  2  4  NaN
3  2  4  1.0
```

(continues on next page)

(continued from previous page)

```
4 2 4 1.0
```

In [84]: pd.crosstab(df["A"], df["B"])

Out[84]:

```
B 3 4  
A  
1 1 0  
2 1 3
```

`crosstab()` can also be implemented to [Categorical](#) data.

In [85]: foo = pd.Categorical(["a", "b"], categories=["a", "b", "c"])

In [86]: bar = pd.Categorical(["d", "e"], categories=["d", "e", "f"])

In [87]: pd.crosstab(foo, bar)

Out[87]:

```
col_0 d e  
row_0  
a 1 0  
b 0 1
```

If you want to include **all** of data categories even if the actual data does not contain any instances of a particular category, you should set `dropna=False`.

For example:

In [88]: pd.crosstab(foo, bar, dropna=False)

Out[88]:

```
col_0 d e f  
row_0  
a 1 0 0  
b 0 1 0  
c 0 0 0
```

Normalization

Frequency tables can also be normalized to show percentages rather than counts using the `normalize` argument:

In [89]: pd.crosstab(df["A"], df["B"], normalize=True)

Out[89]:

```
B 3 4  
A  
1 0.2 0.0  
2 0.2 0.6
```

`normalize` can also normalize values within each row or within each column:

In [90]: pd.crosstab(df["A"], df["B"], normalize="columns")

Out[90]:

```
B 3 4  
A
```

(continues on next page)

(continued from previous page)

```
1 0.5 0.0
2 0.5 1.0
```

`crosstab()` can also be passed a third `Series` and an aggregation function (`aggfunc`) that will be applied to the values of the third `Series` within each group defined by the first two `Series`:

```
In [91]: pd.crosstab(df["A"], df["B"], values=df["C"], aggfunc=np.sum)
Out[91]:
B      3      4
A
1  1.0  NaN
2  1.0  2.0
```

Adding margins

Finally, one can also add margins or normalize this output.

```
In [92]: pd.crosstab(
    ....:     df["A"], df["B"], values=df["C"], aggfunc=np.sum, normalize=True,
    ....: margins=True
    ....: )
....:
Out[92]:
B      3      4      All
A
1    0.25  0.0   0.25
2    0.25  0.5   0.75
All  0.50  0.5   1.00
```

2.8.7 Tiling

The `cut()` function computes groupings for the values of the input array and is often used to transform continuous variables to discrete or categorical variables:

```
In [93]: ages = np.array([10, 15, 13, 12, 23, 25, 28, 59, 60])

In [94]: pd.cut(ages, bins=3)
Out[94]:
[(9.95, 26.667], (9.95, 26.667], (9.95, 26.667], (9.95, 26.667], (9.95, 26.667], (9.95, 26.667],
 [26.667, 43.333], (43.333, 60.0], (43.333, 60.0]]
Categories (3, interval[float64, right]): [(9.95, 26.667] < (26.667, 43.333] < (43.333, 60.0]]
```

If the `bins` keyword is an integer, then equal-width bins are formed. Alternatively we can specify custom bin-edges:

```
In [95]: c = pd.cut(ages, bins=[0, 18, 35, 70])

In [96]: c
Out[96]:
[(0, 18], (0, 18], (0, 18], (0, 18], (18, 35], (18, 35], (18, 35], (35, 70], (35, 70]]
Categories (3, interval[int64, right]): [(0, 18] < (18, 35] < (35, 70]]
```

If the `bins` keyword is an `IntervalIndex`, then these will be used to bin the passed data.:

```
pd.cut([25, 20, 50], bins=c.categories)
```

2.8.8 Computing indicator / dummy variables

To convert a categorical variable into a “dummy” or “indicator” `DataFrame`, for example a column in a `DataFrame` (a `Series`) which has k distinct values, can derive a `DataFrame` containing k columns of 1s and 0s using `get_dummies()`:

```
In [97]: df = pd.DataFrame({"key": list("bbacab"), "data1": range(6)})
```

```
In [98]: pd.get_dummies(df["key"])
```

```
Out[98]:
```

```
   a   b   c  
0  0   1   0  
1  0   1   0  
2  1   0   0  
3  0   0   1  
4  1   0   0  
5  0   1   0
```

Sometimes it’s useful to prefix the column names, for example when merging the result with the original `DataFrame`:

```
In [99]: dummies = pd.get_dummies(df["key"], prefix="key")
```

```
In [100]: dummies
```

```
Out[100]:
```

```
   key_a  key_b  key_c  
0      0      1      0  
1      0      1      0  
2      1      0      0  
3      0      0      1  
4      1      0      0  
5      0      1      0
```

```
In [101]: df[["data1"]].join(dummies)
```

```
Out[101]:
```

```
   data1  key_a  key_b  key_c  
0      0      0      1      0  
1      1      0      1      0  
2      2      1      0      0  
3      3      0      0      1  
4      4      1      0      0  
5      5      0      1      0
```

This function is often used along with discretization functions like `cut()`:

```
In [102]: values = np.random.randn(10)
```

```
In [103]: values
```

```
Out[103]:
```

```
array([ 0.4082, -1.0481, -0.0257, -0.9884,  0.0941,  1.2627,  1.29 ,
```

(continues on next page)

(continued from previous page)

```
0.0824, -0.0558, 0.5366])
```

In [104]: bins = [0, 0.2, 0.4, 0.6, 0.8, 1]

In [105]: pd.get_dummies(pd.cut(values, bins))

Out[105]:

	(0.0, 0.2]	(0.2, 0.4]	(0.4, 0.6]	(0.6, 0.8]	(0.8, 1.0]
0	0	0	1	0	0
1	0	0	0	0	0
2	0	0	0	0	0
3	0	0	0	0	0
4	1	0	0	0	0
5	0	0	0	0	0
6	0	0	0	0	0
7	1	0	0	0	0
8	0	0	0	0	0
9	0	0	1	0	0

See also [Series.str.get_dummies](#).

`get_dummies()` also accepts a [DataFrame](#). By default all categorical variables (categorical in the statistical sense, those with `object` or `categorical` dtype) are encoded as dummy variables.

In [106]: df = pd.DataFrame({"A": ["a", "b", "a"], "B": ["c", "c", "b"], "C": [1, 2, 3]})

In [107]: pd.get_dummies(df)

Out[107]:

	C	A_a	A_b	B_b	B_c
0	1	1	0	0	1
1	2	0	1	0	1
2	3	1	0	1	0

All non-object columns are included untouched in the output. You can control the columns that are encoded with the `columns` keyword.

In [108]: pd.get_dummies(df, columns=["A"])

Out[108]:

	B	C	A_a	A_b
0	c	1	1	0
1	c	2	0	1
2	b	3	1	0

Notice that the `B` column is still included in the output, it just hasn't been encoded. You can drop `B` before calling `get_dummies` if you don't want to include it in the output.

As with the [Series](#) version, you can pass values for the `prefix` and `prefix_sep`. By default the column name is used as the prefix, and `_` as the prefix separator. You can specify `prefix` and `prefix_sep` in 3 ways:

- string: Use the same value for `prefix` or `prefix_sep` for each column to be encoded.
- list: Must be the same length as the number of columns being encoded.
- dict: Mapping column name to prefix.

```
In [109]: simple = pd.get_dummies(df, prefix="new_prefix")  
  
In [110]: simple  
Out[110]:  
   C  new_prefix_a  new_prefix_b  new_prefix_b  new_prefix_c  
0  1            1            0            0            1  
1  2            0            1            0            1  
2  3            1            0            1            0  
  
In [111]: from_list = pd.get_dummies(df, prefix=["from_A", "from_B"])  
  
In [112]: from_list  
Out[112]:  
   C  from_A_a  from_A_b  from_B_b  from_B_c  
0  1          1          0          0          1  
1  2          0          1          0          1  
2  3          1          0          1          0  
  
In [113]: from_dict = pd.get_dummies(df, prefix={"B": "from_B", "A": "from_A"})  
  
In [114]: from_dict  
Out[114]:  
   C  from_A_a  from_A_b  from_B_b  from_B_c  
0  1          1          0          0          1  
1  2          0          1          0          1  
2  3          1          0          1          0
```

Sometimes it will be useful to only keep k-1 levels of a categorical variable to avoid collinearity when feeding the result to statistical models. You can switch to this mode by turn on `drop_first`.

```
In [115]: s = pd.Series(list("abcaa"))  
  
In [116]: pd.get_dummies(s)  
Out[116]:  
   a  b  c  
0  1  0  0  
1  0  1  0  
2  0  0  1  
3  1  0  0  
4  1  0  0  
  
In [117]: pd.get_dummies(s, drop_first=True)  
Out[117]:  
   b  c  
0  0  0  
1  1  0  
2  0  1  
3  0  0  
4  0  0
```

When a column contains only one level, it will be omitted in the result.

```
In [118]: df = pd.DataFrame({"A": list("aaaaa"), "B": list("ababc")})
```

(continues on next page)

(continued from previous page)

```
In [119]: pd.get_dummies(df)
Out[119]:
   A_a  B_a  B_b  B_c
0    1    1    0    0
1    1    0    1    0
2    1    1    0    0
3    1    0    1    0
4    1    0    0    1

In [120]: pd.get_dummies(df, drop_first=True)
Out[120]:
   B_b  B_c
0    0    0
1    1    0
2    0    0
3    1    0
4    0    1
```

By default new columns will have `np.uint8` dtype. To choose another dtype, use the `dtype` argument:

```
In [121]: df = pd.DataFrame({"A": list("abc"), "B": [1.1, 2.2, 3.3]})

In [122]: pd.get_dummies(df, dtype=bool).dtypes
Out[122]:
B        float64
A_a      bool
A_b      bool
A_c      bool
dtype: object
```

2.8.9 Factorizing values

To encode 1-d values as an enumerated type use `factorize()`:

```
In [123]: x = pd.Series(["A", "A", np.nan, "B", 3.14, np.inf])

In [124]: x
Out[124]:
0      A
1      A
2    NaN
3      B
4    3.14
5     inf
dtype: object

In [125]: labels, uniques = pd.factorize(x)

In [126]: labels
Out[126]: array([ 0,  0, -1,  1,  2,  3])
```

(continues on next page)

(continued from previous page)

```
In [127]: uniques
Out[127]: Index(['A', 'B', 3.14, inf], dtype='object')
```

Note that `factorize()` is similar to `numpy.unique`, but differs in its handling of NaN:

Note: The following `numpy.unique` will fail under Python 3 with a `TypeError` because of an ordering bug. See also [here](#).

```
In [128]: ser = pd.Series(['A', 'A', np.nan, 'B', 3.14, np.inf])

In [129]: pd.factorize(ser, sort=True)
Out[129]: (array([ 2,  2, -1,  3,  0,  1]), Index([3.14, inf, 'A', 'B'], dtype='object'))

In [130]: np.unique(ser, return_inverse=True)[::-1]
-----
TypeError                                         Traceback (most recent call last)

    331         aux = ar[perm]
    332     else:

TypeError: '<' not supported between instances of 'float' and 'str'
```

Note: If you just want to handle one column as a categorical variable (like R's factor), you can use `df["cat_col"] = pd.Categorical(df["col"])` or `df["cat_col"] = df["col"].astype("category")`. For full docs on `Categorical`, see the [Categorical introduction](#) and the [API documentation](#).

2.8.10 Examples

In this section, we will review frequently asked questions and examples. The column names and relevant column values are named to correspond with how this DataFrame will be pivoted in the answers below.

```
In [131]: np.random.seed([3, 1415])

In [132]: n = 20

In [133]: cols = np.array(["key", "row", "item", "col"])

In [134]: df = cols + pd.DataFrame(
.....:     (np.random.randint(5, size=(n, 4)) // [2, 1, 2, 1]).astype(str)
.....: )
.....:

In [135]: df.columns = cols

In [136]: df = df.join(pd.DataFrame(np.random.rand(n, 2).round(2)).add_prefix("val"))

In [137]: df
Out[137]:
   key    row    item    col  val0  val1
0  key0  row3  item1  col3  0.81  0.04
1  key1  row2  item1  col2  0.44  0.07
2  key1  row0  item1  col0  0.77  0.01
3  key0  row4  item0  col2  0.15  0.59
4  key1  row0  item2  col1  0.81  0.64
..  ...  ...  ...  ...  ...
15 key0  row3  item1  col1  0.31  0.23
16 key0  row0  item2  col3  0.86  0.01
17 key0  row4  item0  col3  0.64  0.21
18 key2  row2  item2  col0  0.13  0.45
19 key0  row2  item0  col4  0.37  0.70

[20 rows x 6 columns]
```

Pivoting with single aggregations

Suppose we wanted to pivot df such that the col values are columns, row values are the index, and the mean of val0 are the values? In particular, the resulting DataFrame should look like:

col	col0	col1	col2	col3	col4
row					
row0	0.77	0.605	NaN	0.860	0.65
row2	0.13	NaN	0.395	0.500	0.25
row3	NaN	0.310	NaN	0.545	NaN
row4	NaN	0.100	0.395	0.760	0.24

This solution uses `pivot_table()`. Also note that `aggfunc='mean'` is the default. It is included here to be explicit.

```
In [138]: df.pivot_table(values="val0", index="row", columns="col", aggfunc="mean")
Out[138]:
```

(continues on next page)

(continued from previous page)

col	col0	col1	col2	col3	col4
row					
row0	0.77	0.605	NaN	0.860	0.65
row2	0.13	NaN	0.395	0.500	0.25
row3	NaN	0.310	NaN	0.545	NaN
row4	NaN	0.100	0.395	0.760	0.24

Note that we can also replace the missing values by using the `fill_value` parameter.

```
In [139]: df.pivot_table(
    .....
    values="val0",
    index="row",
    columns="col",
    aggfunc="mean",
    fill_value=0,
    .....
    .....

Out[139]:
col    col0    col1    col2    col3    col4
row
row0  0.77  0.605  0.000  0.860  0.65
row2  0.13  0.000  0.395  0.500  0.25
row3  0.00  0.310  0.000  0.545  0.00
row4  0.00  0.100  0.395  0.760  0.24
```

Also note that we can pass in other aggregation functions as well. For example, we can also pass in `sum`.

```
In [140]: df.pivot_table(
    .....
    values="val0",
    index="row",
    columns="col",
    aggfunc="sum",
    fill_value=0,
    .....
    .....

Out[140]:
col    col0    col1    col2    col3    col4
row
row0  0.77  1.21  0.00  0.86  0.65
row2  0.13  0.00  0.79  0.50  0.50
row3  0.00  0.31  0.00  1.09  0.00
row4  0.00  0.10  0.79  1.52  0.24
```

Another aggregation we can do is calculate the frequency in which the columns and rows occur together a.k.a. “cross tabulation”. To do this, we can pass `size` to the `aggfunc` parameter.

```
In [141]: df.pivot_table(index="row", columns="col", fill_value=0, aggfunc="size")
Out[141]:
col    col0    col1    col2    col3    col4
row
row0      1      2      0      1      1
row2      1      0      2      1      2
```

(continues on next page)

(continued from previous page)

row3	0	1	0	2	0
row4	0	1	2	2	1

Pivoting with multiple aggregations

We can also perform multiple aggregations. For example, to perform both a `sum` and `mean`, we can pass in a list to the `aggfunc` argument.

```
In [142]: df.pivot_table(
    ....:     values="val0",
    ....:     index="row",
    ....:     columns="col",
    ....:     aggfunc=["mean", "sum"],
    ....: )
....:

Out[142]:
      mean                               sum
  col   col0   col1   col2   col3   col4   col0   col1   col2   col3   col4
row
row0  0.77  0.605     NaN  0.860  0.65  0.77  1.21     NaN  0.86  0.65
row2  0.13     NaN  0.395  0.500  0.25  0.13     NaN  0.79  0.50  0.50
row3    NaN  0.310     NaN  0.545     NaN     NaN  0.31     NaN  1.09     NaN
row4    NaN  0.100  0.395  0.760  0.24     NaN  0.10  0.79  1.52  0.24
```

Note to aggregate over multiple value columns, we can pass in a list to the `values` parameter.

```
In [143]: df.pivot_table(
    ....:     values=["val0", "val1"],
    ....:     index="row",
    ....:     columns="col",
    ....:     aggfunc=["mean"],
    ....: )
....:

Out[143]:
      mean
      val0           val1
  col   col0   col1   col2   col3   col4   col0   col1   col2   col3   col4
row
row0  0.77  0.605     NaN  0.860  0.65  0.01  0.745     NaN  0.010  0.02
row2  0.13     NaN  0.395  0.500  0.25  0.45     NaN  0.34  0.440  0.79
row3    NaN  0.310     NaN  0.545     NaN     NaN  0.230     NaN  0.075     NaN
row4    NaN  0.100  0.395  0.760  0.24     NaN  0.070  0.42  0.300  0.46
```

Note to subdivide over multiple columns we can pass in a list to the `columns` parameter.

```
In [144]: df.pivot_table(
    ....:     values=["val0"],
    ....:     index="row",
    ....:     columns=["item", "col"],
    ....:     aggfunc=["mean"],
    ....: )
....:
```

(continues on next page)

(continued from previous page)

```
.....
Out[144]:
mean
val0
item item0           item1           item2
col  col2  col3  col4  col0  col1  col2  col3  col4  col0  col1  col3  col4
row
row0   NaN   NaN   NaN  0.77   NaN   NaN   NaN   NaN  0.605  0.86  0.65
row2  0.35   NaN  0.37   NaN   NaN  0.44   NaN   NaN  0.13   NaN  0.50  0.13
row3   NaN   NaN   NaN   NaN  0.31   NaN  0.81   NaN   NaN  0.28   NaN
row4  0.15  0.64   NaN   NaN  0.10  0.64  0.88  0.24   NaN   NaN   NaN
```

2.8.11 Exploding a list-like column

New in version 0.25.0.

Sometimes the values in a column are list-like.

```
In [145]: keys = ["panda1", "panda2", "panda3"]

In [146]: values = [[["eats", "shoots"], ["shoots", "leaves"], ["eats", "leaves"]]

In [147]: df = pd.DataFrame({"keys": keys, "values": values})

In [148]: df
Out[148]:
      keys          values
0  panda1    [eats, shoots]
1  panda2  [shoots, leaves]
2  panda3    [eats, leaves]
```

We can ‘explode’ the `values` column, transforming each list-like to a separate row, by using `explode()`. This will replicate the index values from the original row:

```
In [149]: df["values"].explode()
Out[149]:
0      eats
0      shoots
1      shoots
1      leaves
2      eats
2      leaves
Name: values, dtype: object
```

You can also explode the column in the `DataFrame`.

```
In [150]: df.explode("values")
Out[150]:
      keys  values
0  panda1    eats
0  panda1  shoots
1  panda2  shoots
```

(continues on next page)

(continued from previous page)

```
1 panda2  leaves
2 panda3   eats
2 panda3  leaves
```

`Series.explode()` will replace empty lists with `np.nan` and preserve scalar entries. The dtype of the resulting `Series` is always `object`.

```
In [151]: s = pd.Series([[1, 2, 3], "foo", [], ["a", "b"]])
```

```
In [152]: s
```

```
Out[152]:
```

```
0    [1, 2, 3]
1          foo
2        []
3      [a, b]
dtype: object
```

```
In [153]: s.explode()
```

```
Out[153]:
```

```
0      1
0      2
0      3
1    foo
2    NaN
3      a
3      b
dtype: object
```

Here is a typical usecase. You have comma separated strings in a column and want to expand this.

```
In [154]: df = pd.DataFrame([{"var1": "a,b,c", "var2": 1}, {"var1": "d,e,f", "var2": 2}])
```

```
In [155]: df
```

```
Out[155]:
```

	var1	var2
0	a,b,c	1
1	d,e,f	2

Creating a long form DataFrame is now straightforward using `explode` and chained operations

```
In [156]: df.assign(var1=df.var1.str.split(",")).explode("var1")
```

```
Out[156]:
```

	var1	var2
0	a	1
0	b	1
0	c	1
1	d	2
1	e	2
1	f	2

2.9 Working with text data

2.9.1 Text data types

New in version 1.0.0.

There are two ways to store text data in pandas:

1. `object`-dtype NumPy array.
2. `StringDtype` extension type.

We recommend using `StringDtype` to store text data.

Prior to pandas 1.0, `object` dtype was the only option. This was unfortunate for many reasons:

1. You can accidentally store a *mixture* of strings and non-strings in an `object` dtype array. It's better to have a dedicated dtype.
2. `object` dtype breaks dtype-specific operations like `DataFrame.select_dtypes()`. There isn't a clear way to select *just* text while excluding non-text but still object-dtype columns.
3. When reading code, the contents of an `object` dtype array is less clear than '`string`'.

Currently, the performance of `object` dtype arrays of strings and `arrays.StringArray` are about the same. We expect future enhancements to significantly increase the performance and lower the memory overhead of `StringArray`.

Warning: `StringArray` is currently considered experimental. The implementation and parts of the API may change without warning.

For backwards-compatibility, `object` dtype remains the default type we infer a list of strings to

```
In [1]: pd.Series(["a", "b", "c"])
Out[1]:
0    a
1    b
2    c
dtype: object
```

To explicitly request `string` dtype, specify the `dtype`

```
In [2]: pd.Series(["a", "b", "c"], dtype="string")
Out[2]:
0    a
1    b
2    c
dtype: string

In [3]: pd.Series(["a", "b", "c"], dtype=pd.StringDtype())
Out[3]:
0    a
1    b
2    c
dtype: string
```

Or `astype` after the `Series` or `DataFrame` is created

```
In [4]: s = pd.Series(["a", "b", "c"])
```

```
In [5]: s
```

```
Out[5]:
```

```
0    a  
1    b  
2    c  
dtype: object
```

```
In [6]: s.astype("string")
```

```
Out[6]:
```

```
0    a  
1    b  
2    c  
dtype: string
```

Changed in version 1.1.0.

You can also use *StringDtype*/"string" as the dtype on non-string data and it will be converted to `string` dtype:

```
In [7]: s = pd.Series(["a", 2, np.nan], dtype="string")
```

```
In [8]: s
```

```
Out[8]:
```

```
0    a  
1    2  
2    <NA>  
dtype: string
```

```
In [9]: type(s[1])
```

```
Out[9]: str
```

or convert from existing pandas data:

```
In [10]: s1 = pd.Series([1, 2, np.nan], dtype="Int64")
```

```
In [11]: s1
```

```
Out[11]:
```

```
0    1  
1    2  
2    <NA>  
dtype: Int64
```

```
In [12]: s2 = s1.astype("string")
```

```
In [13]: s2
```

```
Out[13]:
```

```
0    1  
1    2  
2    <NA>  
dtype: string
```

```
In [14]: type(s2[0])
```

```
Out[14]: str
```

Behavior differences

These are places where the behavior of `StringDtype` objects differ from `object` dtype

1. For `StringDtype`, *string accessor methods* that return `numeric` output will always return a nullable integer dtype, rather than either int or float dtype, depending on the presence of NA values. Methods returning `boolean` output will return a nullable boolean dtype.

```
In [15]: s = pd.Series(["a", None, "b"], dtype="string")

In [16]: s
Out[16]:
0      a
1    <NA>
2      b
dtype: string

In [17]: s.str.count("a")
Out[17]:
0      1
1    <NA>
2      0
dtype: Int64

In [18]: s.dropna().str.count("a")
Out[18]:
0      1
2      0
dtype: Int64
```

Both outputs are Int64 dtype. Compare that with object-dtype

```
In [19]: s2 = pd.Series(["a", None, "b"], dtype="object")

In [20]: s2.str.count("a")
Out[20]:
0    1.0
1    NaN
2    0.0
dtype: float64

In [21]: s2.dropna().str.count("a")
Out[21]:
0      1
2      0
dtype: int64
```

When NA values are present, the output dtype is float64. Similarly for methods returning boolean values.

```
In [22]: s.str.isdigit()
Out[22]:
0    False
1    <NA>
2    False
```

(continues on next page)

(continued from previous page)

```

dtype: boolean

In [23]: s.str.match("a")
Out[23]:
0    True
1    <NA>
2   False
dtype: boolean

```

2. Some string methods, like `Series.str.decode()` are not available on `StringArray` because `StringArray` only holds strings, not bytes.
3. In comparison operations, `arrays.StringArray` and `Series` backed by a `StringArray` will return an object with `BooleanDtype`, rather than a `bool` dtype object. Missing values in a `StringArray` will propagate in comparison operations, rather than always comparing unequal like `numpy.nan`.

Everything else that follows in the rest of this document applies equally to `string` and `object` dtype.

2.9.2 String methods

`Series` and `Index` are equipped with a set of string processing methods that make it easy to operate on each element of the array. Perhaps most importantly, these methods exclude missing/NA values automatically. These are accessed via the `str` attribute and generally have names matching the equivalent (scalar) built-in string methods:

```

In [24]: s = pd.Series(
    ....:     ["A", "B", "C", "Aaba", "Baca", np.nan, "CABA", "dog", "cat"], dtype="string"
    ↵
    ....: )
    ....:

In [25]: s.str.lower()
Out[25]:
0      a
1      b
2      c
3     aaba
4     baca
5    <NA>
6     caba
7     dog
8     cat
dtype: string

In [26]: s.str.upper()
Out[26]:
0      A
1      B
2      C
3     AABA
4     BACA
5    <NA>
6     CABA

```

(continues on next page)

(continued from previous page)

```
7    DOG
8    CAT
dtype: string
```

In [27]: `s.str.len()`

Out[27]:

```
0      1
1      1
2      1
3      4
4      4
5    <NA>
6      4
7      3
8      3
dtype: Int64
```

In [28]: `idx = pd.Index([" jack", "jill ", " jesse ", "frank"])`

In [29]: `idx.str.strip()`

Out[29]: `Index(['jack', 'jill', 'jesse', 'frank'], dtype='object')`

In [30]: `idx.str.lstrip()`

Out[30]: `Index(['jack', 'jill ', 'jesse ', 'frank'], dtype='object')`

In [31]: `idx.str.rstrip()`

Out[31]: `Index([' jack', 'jill', ' jesse', 'frank'], dtype='object')`

The string methods on Index are especially useful for cleaning up or transforming DataFrame columns. For instance, you may have columns with leading or trailing whitespace:

In [32]: `df = pd.DataFrame(
.....: np.random.randn(3, 2), columns=[" Column A ", " Column B "], index=range(3)
.....:
.....:`

In [33]: `df`

Out[33]:

	Column A	Column B
0	0.469112	-0.282863
1	-1.509059	-1.135632
2	1.212112	-0.173215

Since `df.columns` is an Index object, we can use the `.str` accessor

In [34]: `df.columns.str.strip()`

Out[34]: `Index(['Column A', 'Column B'], dtype='object')`

In [35]: `df.columns.str.lower()`

Out[35]: `Index([' column a ', ' column b '], dtype='object')`

These string methods can then be used to clean up the columns as needed. Here we are removing leading and trailing whitespaces, lower casing all names, and replacing any remaining whitespaces with underscores:

```
In [36]: df.columns = df.columns.str.strip().str.lower().str.replace(" ", "_")
```

```
In [37]: df
```

```
Out[37]:
```

	column_a	column_b
0	0.469112	-0.282863
1	-1.509059	-1.135632
2	1.212112	-0.173215

Note: If you have a `Series` where lots of elements are repeated (i.e. the number of unique elements in the `Series` is a lot smaller than the length of the `Series`), it can be faster to convert the original `Series` to one of type `category` and then use `.str.<method>` or `.dt.<property>` on that. The performance difference comes from the fact that, for `Series` of type `category`, the string operations are done on the `.categories` and not on each element of the `Series`.

Please note that a `Series` of type `category` with string `.categories` has some limitations in comparison to `Series` of type `string` (e.g. you can't add strings to each other: `s + " " + s` won't work if `s` is a `Series` of type `category`). Also, `.str` methods which operate on elements of type `list` are not available on such a `Series`.

Warning: Before v.0.25.0, the `.str`-accessor did only the most rudimentary type checks. Starting with v.0.25.0, the type of the `Series` is inferred and the allowed types (i.e. strings) are enforced more rigorously.

Generally speaking, the `.str` accessor is intended to work only on strings. With very few exceptions, other uses are not supported, and may be disabled at a later point.

2.9.3 Splitting and replacing strings

Methods like `split` return a `Series` of lists:

```
In [38]: s2 = pd.Series(["a_b_c", "c_d_e", np.nan, "f_g_h"], dtype="string")
```

```
In [39]: s2.str.split("_")
```

```
Out[39]:
```

0	[a, b, c]
1	[c, d, e]
2	<NA>
3	[f, g, h]

`dtype: object`

Elements in the split lists can be accessed using `get` or `[]` notation:

```
In [40]: s2.str.split("_").str.get(1)
```

```
Out[40]:
```

0	b
1	d
2	<NA>
3	g

`dtype: object`

```
In [41]: s2.str.split("_").str[1]
```

```
Out[41]:
```

(continues on next page)

(continued from previous page)

```
0      b
1      d
2    <NA>
3      g
dtype: object
```

It is easy to expand this to return a DataFrame using `expand`.

```
In [42]: s2.str.split("_", expand=True)
Out[42]:
   0    1    2
0  a  b  c
1  c  d  e
2  <NA>  <NA>  <NA>
3  f  g  h
```

When original Series has `StringDtype`, the output columns will all be `StringDtype` as well.

It is also possible to limit the number of splits:

```
In [43]: s2.str.split("_", expand=True, n=1)
Out[43]:
   0    1
0  a  b_c
1  c  d_e
2  <NA>  <NA>
3  f  g_h
```

`rsplit` is similar to `split` except it works in the reverse direction, i.e., from the end of the string to the beginning of the string:

```
In [44]: s2.str.rsplit("_", expand=True, n=1)
Out[44]:
   0    1
0  a_b  c
1  c_d  e
2  <NA>  <NA>
3  f_g  h
```

`replace` optionally uses regular expressions:

```
In [45]: s3 = pd.Series(
....:     ["A", "B", "C", "Aaba", "Baca", "", np.nan, "CABA", "dog", "cat"],
....:     dtype="string",
....: )
....:

In [46]: s3
Out[46]:
0      A
1      B
2      C
3    Aaba
```

(continues on next page)

(continued from previous page)

```

4    Baca
5
6    <NA>
7    CABA
8    dog
9    cat
dtype: string

In [47]: s3.str.replace("^a|dog", "XX-XX ", case=False, regex=True)
Out[47]:
0      A
1      B
2      C
3    XX-XX ba
4    XX-XX ca
5
6    <NA>
7    XX-XX BA
8    XX-XX
9    XX-XX t
dtype: string

```

Warning: Some caution must be taken when dealing with regular expressions! The current behavior is to treat single character patterns as literal strings, even when `regex` is set to True. This behavior is deprecated and will be removed in a future version so that the `regex` keyword is always respected.

Changed in version 1.2.0.

If you want literal replacement of a string (equivalent to `str.replace()`), you can set the optional `regex` parameter to `False`, rather than escaping each character. In this case both `pat` and `repl` must be strings:

```

In [48]: dollars = pd.Series(["12", "-$10", "$10,000"], dtype="string")

# These lines are equivalent
In [49]: dollars.str.replace(r"-\$", "-", regex=True)
Out[49]:
0      12
1     -10
2    $10,000
dtype: string

In [50]: dollars.str.replace("-$", "-", regex=False)
Out[50]:
0      12
1     -10
2    $10,000
dtype: string

```

The `replace` method can also take a callable as replacement. It is called on every `pat` using `re.sub()`. The callable should expect one positional argument (a regex object) and return a string.

```
# Reverse every lowercase alphabetic word
In [51]: pat = r"[a-z]+"

In [52]: def repl(m):
....:     return m.group(0)[::-1]
....:

In [53]: pd.Series(["foo 123", "bar baz", np.nan], dtype="string").str.replace(
....:     pat, repl, regex=True
....: )
....:
Out[53]:
0    oof 123
1    rab zab
2    <NA>
dtype: string

# Using regex groups
In [54]: pat = r"(?P<one>\w+) (?P<two>\w+) (?P<three>\w+)"
```

```
In [55]: def repl(m):
....:     return m.group("two").swapcase()
....:

In [56]: pd.Series(["Foo Bar Baz", np.nan], dtype="string").str.replace(
....:     pat, repl, regex=True
....: )
....:
Out[56]:
0    bAR
1    <NA>
dtype: string
```

The `replace` method also accepts a compiled regular expression object from `re.compile()` as a pattern. All flags should be included in the compiled regular expression object.

```
In [57]: import re

In [58]: regex_pat = re.compile(r"^.a|dog", flags=re.IGNORECASE)

In [59]: s3.str.replace(regex_pat, "XX-XX ", regex=True)
Out[59]:
0        A
1        B
2        C
3    XX-XX ba
4    XX-XX ca
5
6        <NA>
7    XX-XX BA
8    XX-XX
9    XX-XX t
dtype: string
```

Including a `flags` argument when calling `replace` with a compiled regular expression object will raise a `ValueError`.

```
In [60]: s3.str.replace(regex_pat, 'XX-XX ', flags=re.IGNORECASE)
```

```
ValueError: case and flags cannot be set when pat is a compiled regex
```

`removeprefix` and `removesuffix` have the same effect as `str.removeprefix` and `str.removesuffix` added in Python 3.9 <<https://docs.python.org/3/library/stdtypes.html#str.removeprefix>>`__:

New in version 1.4.0.

```
In [61]: s = pd.Series(["str_foo", "str_bar", "no_prefix"])
```

```
In [62]: s.str.removeprefix("str_")
```

```
Out[62]:
```

```
0      foo
1      bar
2  no_prefix
dtype: object
```

```
In [63]: s = pd.Series(["foo_str", "bar_str", "no_suffix"])
```

```
In [64]: s.str.removesuffix("_str")
```

```
Out[64]:
```

```
0      foo
1      bar
2  no_suffix
dtype: object
```

2.9.4 Concatenation

There are several ways to concatenate a `Series` or `Index`, either with itself or others, all based on `cat()`, resp. `Index.str.cat`.

Concatenating a single Series into a string

The content of a `Series` (or `Index`) can be concatenated:

```
In [65]: s = pd.Series(["a", "b", "c", "d"], dtype="string")
```

```
In [66]: s.str.cat(sep=",")
```

```
Out[66]: 'a,b,c,d'
```

If not specified, the keyword `sep` for the separator defaults to the empty string, `sep=' '`:

```
In [67]: s.str.cat()
```

```
Out[67]: 'abcd'
```

By default, missing values are ignored. Using `na_rep`, they can be given a representation:

```
In [68]: t = pd.Series(["a", "b", np.nan, "d"], dtype="string")
```

```
In [69]: t.str.cat(sep=",")
```

(continues on next page)

(continued from previous page)

```
Out[69]: 'a,b,d'
```

```
In [70]: t.str.cat(sep=",", na_rep="-")
```

```
Out[70]: 'a,b,-,d'
```

Concatenating a Series and something list-like into a Series

The first argument to `cat()` can be a list-like object, provided that it matches the length of the calling Series (or Index).

```
In [71]: s.str.cat(["A", "B", "C", "D"])
```

```
Out[71]:
```

```
0    aA  
1    bB  
2    cC  
3    dD  
dtype: string
```

Missing values on either side will result in missing values in the result as well, *unless* `na_rep` is specified:

```
In [72]: s.str.cat(t)
```

```
Out[72]:
```

```
0    aa  
1    bb  
2    <NA>  
3    dd  
dtype: string
```

```
In [73]: s.str.cat(t, na_rep="-")
```

```
Out[73]:
```

```
0    aa  
1    bb  
2    c-  
3    dd  
dtype: string
```

Concatenating a Series and something array-like into a Series

The parameter `others` can also be two-dimensional. In this case, the number of rows must match the lengths of the calling Series (or Index).

```
In [74]: d = pd.concat([t, s], axis=1)
```

```
In [75]: s
```

```
Out[75]:
```

```
0    a  
1    b  
2    c  
3    d  
dtype: string
```

(continues on next page)

(continued from previous page)

```
In [76]: d
Out[76]:
0    1
0    a  a
1    b  b
2  <NA>  c
3    d  d

In [77]: s.str.cat(d, na_rep="-")
Out[77]:
0    aaa
1    bbb
2    c-c
3    ddd
dtype: string
```

Concatenating a Series and an indexed object into a Series, with alignment

For concatenation with a Series or DataFrame, it is possible to align the indexes before concatenation by setting the `join`-keyword.

```
In [78]: u = pd.Series(["b", "d", "a", "c"], index=[1, 3, 0, 2], dtype="string")

In [79]: s
Out[79]:
0    a
1    b
2    c
3    d
dtype: string

In [80]: u
Out[80]:
1    b
3    d
0    a
2    c
dtype: string

In [81]: s.str.cat(u)
Out[81]:
0    aa
1    bb
2    cc
3    dd
dtype: string

In [82]: s.str.cat(u, join="left")
Out[82]:
0    aa
```

(continues on next page)

(continued from previous page)

```
1    bb
2    cc
3    dd
dtype: string
```

Warning: If the `join` keyword is not passed, the method `cat()` will currently fall back to the behavior before version 0.23.0 (i.e. no alignment), but a `FutureWarning` will be raised if any of the involved indexes differ, since this default will change to `join='left'` in a future version.

The usual options are available for `join` (one of `'left'`, `'outer'`, `'inner'`, `'right'`). In particular, alignment also means that the different lengths do not need to coincide anymore.

```
In [83]: v = pd.Series(["z", "a", "b", "d", "e"], index=[-1, 0, 1, 3, 4], dtype="string")
```

```
In [84]: s
```

```
Out[84]:
```

```
0    a
1    b
2    c
3    d
dtype: string
```

```
In [85]: v
```

```
Out[85]:
```

```
-1    z
0    a
1    b
3    d
4    e
dtype: string
```

```
In [86]: s.str.cat(v, join="left", na_rep="-")
```

```
Out[86]:
```

```
0    aa
1    bb
2    c-
3    dd
dtype: string
```

```
In [87]: s.str.cat(v, join="outer", na_rep="-")
```

```
Out[87]:
```

```
-1    -z
0    aa
1    bb
2    c-
3    dd
4    -e
dtype: string
```

The same alignment can be used when `others` is a `DataFrame`:

```
In [88]: f = d.loc[[3, 2, 1, 0], :]

In [89]: s
Out[89]:
0    a
1    b
2    c
3    d
dtype: string

In [90]: f
Out[90]:
   0  1
3  d  d
2  <NA>  c
1    b  b
0    a  a

In [91]: s.str.cat(f, join="left", na_rep="-")
Out[91]:
0    aaa
1    bbb
2    c-c
3    ddd
dtype: string
```

Concatenating a Series and many objects into a Series

Several array-like items (specifically: `Series`, `Index`, and 1-dimensional variants of `np.ndarray`) can be combined in a list-like container (including iterators, `dict`-views, etc.).

```
In [92]: s
Out[92]:
0    a
1    b
2    c
3    d
dtype: string

In [93]: u
Out[93]:
1    b
3    d
0    a
2    c
dtype: string

In [94]: s.str.cat([u, u.to_numpy()], join="left")
Out[94]:
0    aab
1    bbd
2    cca
```

(continues on next page)

(continued from previous page)

```
3    ddc
dtype: string
```

All elements without an index (e.g. `np.ndarray`) within the passed list-like must match in length to the calling `Series` (or `Index`), but `Series` and `Index` may have arbitrary length (as long as alignment is not disabled with `join=None`):

```
In [95]: v
Out[95]:
-1      z
 0      a
 1      b
 3      d
 4      e
dtype: string
```

```
In [96]: s.str.cat([v, u, u.to_numpy()], join="outer", na_rep="-")
Out[96]:
-1      -z--
 0      aaab
 1      bbbd
 2      c-ca
 3      dddc
 4      -e--
dtype: string
```

If using `join='right'` on a list-like of `others` that contains different indexes, the union of these indexes will be used as the basis for the final concatenation:

```
In [97]: u.loc[[3]]
Out[97]:
3      d
dtype: string
```

```
In [98]: v.loc[[-1, 0]]
Out[98]:
-1      z
 0      a
dtype: string
```

```
In [99]: s.str.cat([u.loc[[3]], v.loc[[-1, 0]]], join="right", na_rep="-")
Out[99]:
 3      dd-
 -1      --z
 0      a-a
dtype: string
```

2.9.5 Indexing with .str

You can use [] notation to directly index by position locations. If you index past the end of the string, the result will be a NaN.

```
In [100]: s = pd.Series([
    ....:     ["A", "B", "C", "Aaba", "Baca", np.nan, "CABA", "dog", "cat"], dtype=
    ....:     "string"
    ....: )
    ....:

In [101]: s.str[0]
Out[101]:
0      A
1      B
2      C
3      A
4      B
5    <NA>
6      C
7      d
8      c
dtype: string

In [102]: s.str[1]
Out[102]:
0    <NA>
1    <NA>
2    <NA>
3      a
4      a
5    <NA>
6      A
7      o
8      a
dtype: string
```

2.9.6 Extracting substrings

Extract first match in each subject (extract)

Warning: Before version 0.23, argument `expand` of the `extract` method defaulted to `False`. When `expand=False`, `expand` returns a Series, Index, or DataFrame, depending on the subject and regular expression pattern. When `expand=True`, it always returns a DataFrame, which is more consistent and less confusing from the perspective of a user. `expand=True` has been the default since version 0.23.0.

The `extract` method accepts a [regular expression](#) with at least one capture group.

Extracting a regular expression with more than one group returns a DataFrame with one column per group.

```
In [103]: pd.Series(  
.....:     ["a1", "b2", "c3"],  
.....:     dtype="string",  
.....: ).str.extract(r"([ab])(\d)", expand=False)  
.....:  
Out[103]:  
      0    1  
0    a    1  
1    b    2  
2  <NA>  <NA>
```

Elements that do not match return a row filled with NaN. Thus, a Series of messy strings can be “converted” into a like-indexed Series or DataFrame of cleaned-up or more useful strings, without necessitating get() to access tuples or re.match objects. The dtype of the result is always object, even if no match is found and the result only contains NaN.

Named groups like

```
In [104]: pd.Series(["a1", "b2", "c3"], dtype="string").str.extract(  
.....:     r"(?P<letter>[ab])(?P<digit>\d)", expand=False  
.....: )  
.....:  
Out[104]:  
   letter  digit  
0        a      1  
1        b      2  
2      <NA>  <NA>
```

and optional groups like

```
In [105]: pd.Series(  
.....:     ["a1", "b2", "3"],  
.....:     dtype="string",  
.....: ).str.extract(r"([ab])?(\d)", expand=False)  
.....:  
Out[105]:  
      0    1  
0    a    1  
1    b    2  
2  <NA>  3
```

can also be used. Note that any capture group names in the regular expression will be used for column names; otherwise capture group numbers will be used.

Extracting a regular expression with one group returns a DataFrame with one column if expand=True.

```
In [106]: pd.Series(["a1", "b2", "c3"], dtype="string").str.extract(r"[ab](\d)",  
.....: expand=True)  
Out[106]:  
      0  
0    1  
1    2  
2  <NA>
```

It returns a Series if expand=False.

```
In [107]: pd.Series(["a1", "b2", "c3"], dtype="string").str.extract(r"[ab](\d)", expand=False)
Out[107]:
0      1
1      2
2    <NA>
dtype: string
```

Calling on an Index with a regex with exactly one capture group returns a DataFrame with one column if expand=True.

```
In [108]: s = pd.Series(["a1", "b2", "c3"], ["A11", "B22", "C33"], dtype="string")
```

```
In [109]: s
Out[109]:
A11    a1
B22    b2
C33    c3
dtype: string
```

```
In [110]: s.index.str.extract("(?P<letter>[a-zA-Z])", expand=True)
```

```
Out[110]:
letter
0      A
1      B
2      C
```

It returns an Index if expand=False.

```
In [111]: s.index.str.extract("(?P<letter>[a-zA-Z])", expand=False)
```

```
Out[111]: Index(['A', 'B', 'C'], dtype='object', name='letter')
```

Calling on an Index with a regex with more than one capture group returns a DataFrame if expand=True.

```
In [112]: s.index.str.extract("(?P<letter>[a-zA-Z])([0-9]+)", expand=True)
Out[112]:
letter   1
0      A  11
1      B  22
2      C  33
```

It raises ValueError if expand=False.

```
>>> s.index.str.extract("(?P<letter>[a-zA-Z])([0-9]+)", expand=False)
ValueError: only one regex group is supported with Index
```

The table below summarizes the behavior of extract(expand=False) (input subject in first column, number of groups in regex in first row)

	1 group	>1 group
Index	Index	ValueError
Series	Series	DataFrame

Extract all matches in each subject (extractall)

Unlike `extract` (which returns only the first match),

```
In [113]: s = pd.Series(["a1a2", "b1", "c1"], index=["A", "B", "C"], dtype="string")
```

```
In [114]: s
```

```
Out[114]:
```

```
A    a1a2  
B      b1  
C      c1  
dtype: string
```

```
In [115]: two_groups = "(?P<letter>[a-z])(?P<digit>[0-9])"
```

```
In [116]: s.str.extract(two_groups, expand=True)
```

```
Out[116]:
```

```
   letter digit  
A      a      1  
B      b      1  
C      c      1
```

the `extractall` method returns every match. The result of `extractall` is always a DataFrame with a MultiIndex on its rows. The last level of the MultiIndex is named `match` and indicates the order in the subject.

```
In [117]: s.str.extractall(two_groups)
```

```
Out[117]:
```

```
   letter digit  
   match  
A 0      a      1  
   1      a      2  
B 0      b      1  
C 0      c      1
```

When each subject string in the Series has exactly one match,

```
In [118]: s = pd.Series(["a3", "b3", "c2"], dtype="string")
```

```
In [119]: s
```

```
Out[119]:
```

```
0    a3  
1    b3  
2    c2  
dtype: string
```

then `extractall(pat).xs(0, level='match')` gives the same result as `extract(pat)`.

```
In [120]: extract_result = s.str.extract(two_groups, expand=True)
```

```
In [121]: extract_result
```

```
Out[121]:
```

```
   letter digit  
0      a      3  
1      b      3
```

(continues on next page)

(continued from previous page)

```
2      c      2
```

```
In [122]: extractall_result = s.str.extractall(two_groups)
```

```
In [123]: extractall_result
```

```
Out[123]:
```

	letter	digit
match		
0 0	a	3
1 0	b	3
2 0	c	2

```
In [124]: extractall_result.xs(0, level="match")
```

```
Out[124]:
```

	letter	digit
0	a	3
1	b	3
2	c	2

Index also supports `.str.extractall`. It returns a DataFrame which has the same result as a `Series.str.extractall` with a default index (starts from 0).

```
In [125]: pd.Index(["a1a2", "b1", "c1"]).str.extractall(two_groups)
```

```
Out[125]:
```

	letter	digit
match		
0 0	a	1
1	a	2
1 0	b	1
2 0	c	1

```
In [126]: pd.Series(["a1a2", "b1", "c1"], dtype="string").str.extractall(two_groups)
```

```
Out[126]:
```

	letter	digit
match		
0 0	a	1
1	a	2
1 0	b	1
2 0	c	1

2.9.7 Testing for strings that match or contain a pattern

You can check whether elements contain a pattern:

```
In [127]: pattern = r"[0-9][a-z]"
```

```
In [128]: pd.Series(
    ....:     ["1", "2", "3a", "3b", "03c", "4dx"],
    ....:     dtype="string",
    ....: ).str.contains(pattern)
    ....:
```

(continues on next page)

(continued from previous page)

Out[128]:

```
0    False
1    False
2     True
3     True
4     True
5     True
dtype: boolean
```

Or whether elements match a pattern:

```
In [129]: pd.Series(
    ....:     ["1", "2", "3a", "3b", "03c", "4dx"],
    ....:     dtype="string",
    ....: ).str.match(pattern)
....:
```

Out[129]:

```
0    False
1    False
2     True
3     True
4    False
5     True
dtype: boolean
```

New in version 1.1.0.

```
In [130]: pd.Series(
    ....:     ["1", "2", "3a", "3b", "03c", "4dx"],
    ....:     dtype="string",
    ....: ).str.fullmatch(pattern)
....:
```

Out[130]:

```
0    False
1    False
2     True
3     True
4    False
5    False
dtype: boolean
```

Note: The distinction between `match`, `fullmatch`, and `contains` is strictness: `fullmatch` tests whether the entire string matches the regular expression; `match` tests whether there is a match of the regular expression that begins at the first character of the string; and `contains` tests whether there is a match of the regular expression at any position within the string.

The corresponding functions in the `re` package for these three match modes are `re.fullmatch`, `re.match`, and `re.search`, respectively.

Methods like `match`, `fullmatch`, `contains`, `startswith`, and `endswith` take an extra `na` argument so missing values can be considered True or False:

```
In [131]: s4 = pd.Series([
    ....:     ["A", "B", "C", "Aaba", "Baca", np.nan, "CABA", "dog", "cat"], dtype=
    ↪"string"
    ....: )
    ....:

In [132]: s4.str.contains("A", na=False)
Out[132]:
0      True
1     False
2     False
3      True
4     False
5     False
6      True
7     False
8     False
dtype: boolean
```

2.9.8 Creating indicator variables

You can extract dummy variables from string columns. For example if they are separated by a '|':

```
In [133]: s = pd.Series(["a", "a|b", np.nan, "a|c"], dtype="string")
```

```
In [134]: s.str.get_dummies(sep="|")
Out[134]:
   a   b   c
0  1   0   0
1  1   1   0
2  0   0   0
3  1   0   1
```

String Index also supports `get_dummies` which returns a MultiIndex.

```
In [135]: idx = pd.Index(["a", "a|b", np.nan, "a|c"])
```

```
In [136]: idx.str.get_dummies(sep="|")
Out[136]:
MultiIndex([(1, 0, 0),
            (1, 1, 0),
            (0, 0, 0),
            (1, 0, 1)],
           names=['a', 'b', 'c'])
```

See also `get_dummies()`.

2.9.9 Method summary

Method	Description
<code>cat()</code>	Concatenate strings
<code>split()</code>	Split strings on delimiter
<code>rsplit()</code>	Split strings on delimiter working from the end of the string
<code>get()</code>	Index into each element (retrieve i-th element)
<code>join()</code>	Join strings in each element of the Series with passed separator
<code>get_dummies()</code>	Split strings on the delimiter returning DataFrame of dummy variables
<code>contains()</code>	Return boolean array if each string contains pattern/regex
<code>replace()</code>	Replace occurrences of pattern/regex/string with some other string or the return value of a callable given the occurrence
<code>removeprefix()</code>	Remove prefix from string, i.e. only remove if string starts with prefix.
<code>removesuffix()</code>	Remove suffix from string, i.e. only remove if string ends with suffix.
<code>repeat()</code>	Duplicate values (<code>s.str.repeat(3)</code> equivalent to <code>x * 3</code>)
<code>pad()</code>	Add whitespace to left, right, or both sides of strings
<code>center()</code>	Equivalent to <code>str.center</code>
<code>ljust()</code>	Equivalent to <code>str.ljust</code>
<code>rjust()</code>	Equivalent to <code>str.rjust</code>
<code>zfill()</code>	Equivalent to <code>str.zfill</code>
<code>wrap()</code>	Split long strings into lines with length less than a given width
<code>slice()</code>	Slice each string in the Series
<code>slice_replace()</code>	Replace slice in each string with passed value
<code>count()</code>	Count occurrences of pattern
<code>startswith()</code>	Equivalent to <code>str.startswith(pat)</code> for each element
<code>endswith()</code>	Equivalent to <code>str.endswith(pat)</code> for each element
<code>findall()</code>	Compute list of all occurrences of pattern/regex for each string
<code>match()</code>	Call <code>re.match</code> on each element, returning matched groups as list
<code>extract()</code>	Call <code>re.search</code> on each element, returning DataFrame with one row for each element and one column for each regex capture group
<code>extractall()</code>	Call <code>re.findall</code> on each element, returning DataFrame with one row for each match and one column for each regex capture group
<code>len()</code>	Compute string lengths
<code>strip()</code>	Equivalent to <code>str.strip</code>
<code>rstrip()</code>	Equivalent to <code>str.rstrip</code>
<code>lstrip()</code>	Equivalent to <code>str.lstrip</code>
<code>partition()</code>	Equivalent to <code>str.partition</code>
<code>rpartition()</code>	Equivalent to <code>str.rpartition</code>
<code>lower()</code>	Equivalent to <code>str.lower</code>
<code>casefold()</code>	Equivalent to <code>str.casefold</code>
<code>upper()</code>	Equivalent to <code>str.upper</code>
<code>find()</code>	Equivalent to <code>str.find</code>
<code>rfind()</code>	Equivalent to <code>str.rfind</code>
<code>index()</code>	Equivalent to <code>str.index</code>
<code>rindex()</code>	Equivalent to <code>str.rindex</code>
<code>capitalize()</code>	Equivalent to <code>str.capitalize</code>
<code>swapcase()</code>	Equivalent to <code>str.swapcase</code>
<code>normalize()</code>	Return Unicode normal form. Equivalent to <code>unicodedata.normalize</code>
<code>translate()</code>	Equivalent to <code>str.translate</code>
<code>isalnum()</code>	Equivalent to <code>str.isalnum</code>
<code>isalpha()</code>	Equivalent to <code>str.isalpha</code>

continues on next page

Table 2 – continued from previous page

Method	Description
<code>isdigit()</code>	Equivalent to <code>str.isdigit</code>
<code>isspace()</code>	Equivalent to <code>str.isspace</code>
<code>islower()</code>	Equivalent to <code>str.islower</code>
<code>isupper()</code>	Equivalent to <code>str.isupper</code>
<code>istitle()</code>	Equivalent to <code>str.istitle</code>
<code>isnumeric()</code>	Equivalent to <code>str.isnumeric</code>
<code>isdecimal()</code>	Equivalent to <code>str.isdecimal</code>

2.10 Working with missing data

In this section, we will discuss missing (also referred to as NA) values in pandas.

Note: The choice of using NaN internally to denote missing data was largely for simplicity and performance reasons. Starting from pandas 1.0, some optional data types start experimenting with a native NA scalar using a mask-based approach. See [here](#) for more.

See the [cookbook](#) for some advanced strategies.

2.10.1 Values considered “missing”

As data comes in many shapes and forms, pandas aims to be flexible with regard to handling missing data. While NaN is the default missing value marker for reasons of computational speed and convenience, we need to be able to easily detect this value with data of different types: floating point, integer, boolean, and general object. In many cases, however, the Python None will arise and we wish to also consider that “missing” or “not available” or “NA”.

Note: If you want to consider inf and -inf to be “NA” in computations, you can set `pandas.options.mode.use_inf_as_na = True`.

```
In [1]: df = pd.DataFrame(
...:     np.random.randn(5, 3),
...:     index=["a", "c", "e", "f", "h"],
...:     columns=["one", "two", "three"],
...: )
...:

In [2]: df["four"] = "bar"

In [3]: df["five"] = df["one"] > 0

In [4]: df
Out[4]:
      one      two      three four five
a  0.469112 -0.282863 -1.509059 bar  True
c -1.135632  1.212112 -0.173215 bar False
e  0.119209 -1.044236 -0.861849 bar  True
f -2.104569 -0.494929  1.071804 bar False
```

(continues on next page)

(continued from previous page)

```
h  0.721555 -0.706771 -1.039575  bar   True
```

In [5]: df2 = df.reindex(["a", "b", "c", "d", "e", "f", "g", "h"])

In [6]: df2

Out[6]:

	one	two	three	four	five
a	0.469112	-0.282863	-1.509059	bar	True
b	NaN	NaN	NaN	NaN	NaN
c	-1.135632	1.212112	-0.173215	bar	False
d	NaN	NaN	NaN	NaN	NaN
e	0.119209	-1.044236	-0.861849	bar	True
f	-2.104569	-0.494929	1.071804	bar	False
g	NaN	NaN	NaN	NaN	NaN
h	0.721555	-0.706771	-1.039575	bar	True

To make detecting missing values easier (and across different array dtypes), pandas provides the `isna()` and `notna()` functions, which are also methods on Series and DataFrame objects:

In [7]: df2["one"]

Out[7]:

```
a    0.469112
b      NaN
c   -1.135632
d      NaN
e    0.119209
f   -2.104569
g      NaN
h    0.721555
Name: one, dtype: float64
```

In [8]: pd.isna(df2["one"])

Out[8]:

```
a    False
b    True
c    False
d    True
e    False
f    False
g    True
h    False
Name: one, dtype: bool
```

In [9]: df2["four"].notna()

Out[9]:

```
a    True
b   False
c    True
d   False
e    True
f    True
g   False
```

(continues on next page)

(continued from previous page)

```
h      True
Name: four, dtype: bool
```

In [10]: df2.isna()

Out[10]:

	one	two	three	four	five
a	False	False	False	False	False
b	True	True	True	True	True
c	False	False	False	False	False
d	True	True	True	True	True
e	False	False	False	False	False
f	False	False	False	False	False
g	True	True	True	True	True
h	False	False	False	False	False

Warning: One has to be mindful that in Python (and NumPy), the `nan`'s don't compare equal, but `None`'s do.
Note that pandas/NumPy uses the fact that `np.nan != np.nan`, and treats `None` like `np.nan`.

In [11]: `None == None` # noqa: E711

Out[11]: True

In [12]: `np.nan == np.nan`

Out[12]: False

So as compared to above, a scalar equality comparison versus a `None`/`np.nan` doesn't provide useful information.

In [13]: df2["one"] == np.nan

Out[13]:

a	False
b	False
c	False
d	False
e	False
f	False
g	False
h	False

Name: one, dtype: bool

Integer dtypes and missing data

Because `NaN` is a float, a column of integers with even one missing values is cast to floating-point dtype (see [Support for integer NA](#) for more). pandas provides a nullable integer array, which can be used by explicitly requesting the dtype:

In [14]: pd.Series([1, 2, np.nan, 4], dtype=pd.Int64Dtype())

Out[14]:

0	1
1	2
2	<NA>
3	4

dtype: Int64

Alternatively, the string alias `dtype='Int64'` (note the capital "I") can be used.

See [Nullable integer data type](#) for more.

Datetimes

For `datetime64[ns]` types, `NaT` represents missing values. This is a pseudo-native sentinel value that can be represented by NumPy in a singular `dtype` (`datetime64[ns]`). pandas objects provide compatibility between `NaT` and `NaN`.

```
In [15]: df2 = df.copy()
```

```
In [16]: df2["timestamp"] = pd.Timestamp("20120101")
```

```
In [17]: df2
```

```
Out[17]:
```

```
one      two      three four      five timestamp
a  0.469112 -0.282863 -1.509059 bar    True 2012-01-01
c -1.135632  1.212112 -0.173215 bar   False 2012-01-01
e  0.119209 -1.044236 -0.861849 bar    True 2012-01-01
f -2.104569 -0.494929  1.071804 bar   False 2012-01-01
h  0.721555 -0.706771 -1.039575 bar    True 2012-01-01
```

```
In [18]: df2.loc[[ "a", "c", "h"], [ "one", "timestamp"]] = np.nan
```

```
In [19]: df2
```

```
Out[19]:
```

```
one      two      three four      five timestamp
a      NaN -0.282863 -1.509059 bar    True      NaT
c      NaN  1.212112 -0.173215 bar   False      NaT
e  0.119209 -1.044236 -0.861849 bar    True 2012-01-01
f -2.104569 -0.494929  1.071804 bar   False 2012-01-01
h      NaN -0.706771 -1.039575 bar    True      NaT
```

```
In [20]: df2.dtypes.value_counts()
```

```
Out[20]:
```

```
float64      3
object       1
bool         1
datetime64[ns]  1
dtype: int64
```

2.10.2 Inserting missing data

You can insert missing values by simply assigning to containers. The actual missing value used will be chosen based on the `dtype`.

For example, numeric containers will always use `NaN` regardless of the missing value type chosen:

```
In [21]: s = pd.Series([1, 2, 3])
```

```
In [22]: s.loc[0] = None
```

(continues on next page)

(continued from previous page)

```
In [23]: s
Out[23]:
0      NaN
1      2.0
2      3.0
dtype: float64
```

Likewise, datetime containers will always use NaT.

For object containers, pandas will use the value given:

```
In [24]: s = pd.Series(["a", "b", "c"])

In [25]: s.loc[0] = None

In [26]: s.loc[1] = np.nan

In [27]: s
Out[27]:
0      None
1      NaN
2      c
dtype: object
```

2.10.3 Calculations with missing data

Missing values propagate naturally through arithmetic operations between pandas objects.

```
In [28]: a
Out[28]:
       one      two
a      NaN -0.282863
c      NaN  1.212112
e  0.119209 -1.044236
f -2.104569 -0.494929
h -2.104569 -0.706771

In [29]: b
Out[29]:
       one      two      three
a      NaN -0.282863 -1.509059
c      NaN  1.212112 -0.173215
e  0.119209 -1.044236 -0.861849
f -2.104569 -0.494929  1.071804
h      NaN -0.706771 -1.039575

In [30]: a + b
Out[30]:
       one      three      two
a      NaN      NaN -0.565727
c      NaN      NaN  2.424224
```

(continues on next page)

(continued from previous page)

e	0.238417	NaN	-2.088472
f	-4.209138	NaN	-0.989859
h		NaN	-1.413542

The descriptive statistics and computational methods discussed in the [data structure overview](#) (and listed [here](#) and [here](#)) are all written to account for missing data. For example:

- When summing data, NA (missing) values will be treated as zero.
- If the data are all NA, the result will be 0.
- Cumulative methods like `cumsum()` and `cumprod()` ignore NA values by default, but preserve them in the resulting arrays. To override this behaviour and include NA values, use `skipna=False`.

```
In [31]: df
Out[31]:
      one      two      three
a    NaN -0.282863 -1.509059
c    NaN  1.212112 -0.173215
e  0.119209 -1.044236 -0.861849
f -2.104569 -0.494929  1.071804
h    NaN -0.706771 -1.039575
```

```
In [32]: df["one"].sum()
Out[32]: -1.9853605075978744
```

```
In [33]: df.mean(1)
Out[33]:
a   -0.895961
c   0.519449
e   -0.595625
f   -0.509232
h   -0.873173
dtype: float64
```

```
In [34]: df.cumsum()
Out[34]:
      one      two      three
a    NaN -0.282863 -1.509059
c    NaN  0.929249 -1.682273
e  0.119209 -0.114987 -2.544122
f -1.985361 -0.609917 -1.472318
h    NaN -1.316688 -2.511893
```

```
In [35]: df.cumsum(skipna=False)
Out[35]:
      one      two      three
a  NaN -0.282863 -1.509059
c  NaN  0.929249 -1.682273
e  NaN -0.114987 -2.544122
f  NaN -0.609917 -1.472318
h  NaN -1.316688 -2.511893
```

2.10.4 Sum/prod of empties/nans

Warning: This behavior is now standard as of v0.22.0 and is consistent with the default in numpy; previously sum/prod of all-NA or empty Series/DataFrames would return NaN. See [v0.22.0 whatsnew](#) for more.

The sum of an empty or all-NA Series or column of a DataFrame is 0.

```
In [36]: pd.Series([np.nan]).sum()
Out[36]: 0.0
```

```
In [37]: pd.Series([], dtype="float64").sum()
Out[37]: 0.0
```

The product of an empty or all-NA Series or column of a DataFrame is 1.

```
In [38]: pd.Series([np.nan]).prod()
Out[38]: 1.0
```

```
In [39]: pd.Series([], dtype="float64").prod()
Out[39]: 1.0
```

2.10.5 NA values in GroupBy

NA groups in GroupBy are automatically excluded. This behavior is consistent with R, for example:

```
In [40]: df
Out[40]:
      one      two      three
a    NaN -0.282863 -1.509059
c    NaN  1.212112 -0.173215
e  0.119209 -1.044236 -0.861849
f -2.104569 -0.494929  1.071804
h    NaN -0.706771 -1.039575
```

```
In [41]: df.groupby("one").mean()
Out[41]:
      two      three
one
-2.104569 -0.494929  1.071804
 0.119209 -1.044236 -0.861849
```

See the groupby section [here](#) for more information.

Cleaning / filling missing data

pandas objects are equipped with various data manipulation methods for dealing with missing data.

2.10.6 Filling missing values: `fillna`

`fillna()` can “fill in” NA values with non-NA data in a couple of ways, which we illustrate:

Replace NA with a scalar value

In [42]: `df2`

Out[42]:

	one	two	three	four	five	timestamp
a	NaN	-0.282863	-1.509059	bar	True	NaT
c	NaN	1.212112	-0.173215	bar	False	NaT
e	0.119209	-1.044236	-0.861849	bar	True	2012-01-01
f	-2.104569	-0.494929	1.071804	bar	False	2012-01-01
h	NaN	-0.706771	-1.039575	bar	True	NaT

In [43]: `df2.fillna(0)`

Out[43]:

	one	two	three	four	five	timestamp
a	0.000000	-0.282863	-1.509059	bar	True	0
c	0.000000	1.212112	-0.173215	bar	False	0
e	0.119209	-1.044236	-0.861849	bar	True	2012-01-01 00:00:00
f	-2.104569	-0.494929	1.071804	bar	False	2012-01-01 00:00:00
h	0.000000	-0.706771	-1.039575	bar	True	0

In [44]: `df2["one"].fillna("missing")`

Out[44]:

a	missing
c	missing
e	0.119209
f	-2.104569
h	missing

Name: one, dtype: object

Fill gaps forward or backward

Using the same filling arguments as `reindexing`, we can propagate non-NA values forward or backward:

In [45]: `df`

Out[45]:

	one	two	three
a	NaN	-0.282863	-1.509059
c	NaN	1.212112	-0.173215
e	0.119209	-1.044236	-0.861849
f	-2.104569	-0.494929	1.071804
h	NaN	-0.706771	-1.039575

In [46]: `df.fillna(method="pad")`

Out[46]:

	one	two	three
a	NaN	-0.282863	-1.509059

(continues on next page)

(continued from previous page)

```
c      NaN  1.212112 -0.173215
e  0.119209 -1.044236 -0.861849
f -2.104569 -0.494929  1.071804
h -2.104569 -0.706771 -1.039575
```

Limit the amount of filling

If we only want consecutive gaps filled up to a certain number of data points, we can use the `limit` keyword:

```
In [47]: df
Out[47]:
   one      two      three
a  NaN -0.282863 -1.509059
c  NaN  1.212112 -0.173215
e  NaN      NaN      NaN
f  NaN      NaN      NaN
h  NaN -0.706771 -1.039575
```

```
In [48]: df.fillna(method="pad", limit=1)
Out[48]:
   one      two      three
a  NaN -0.282863 -1.509059
c  NaN  1.212112 -0.173215
e  NaN  1.212112 -0.173215
f  NaN      NaN      NaN
h  NaN -0.706771 -1.039575
```

To remind you, these are the available filling methods:

Method	Action
<code>pad / ffill</code>	Fill values forward
<code>bfill / backfill</code>	Fill values backward

With time series data, using `pad/ffill` is extremely common so that the “last known value” is available at every time point.

`ffill()` is equivalent to `fillna(method='ffill')` and `bfill()` is equivalent to `fillna(method='bfill')`

2.10.7 Filling with a PandasObject

You can also fillna using a dict or Series that is alignable. The labels of the dict or index of the Series must match the columns of the frame you wish to fill. The use case of this is to fill a DataFrame with the mean of that column.

```
In [49]: dff = pd.DataFrame(np.random.randn(10, 3), columns=list("ABC"))

In [50]: dff.iloc[3:5, 0] = np.nan

In [51]: dff.iloc[4:6, 1] = np.nan

In [52]: dff.iloc[5:8, 2] = np.nan

In [53]: dff
```

(continues on next page)

(continued from previous page)

Out[53]:

	A	B	C
0	0.271860	-0.424972	0.567020
1	0.276232	-1.087401	-0.673690
2	0.113648	-1.478427	0.524988
3	NaN	0.577046	-1.715002
4	NaN	NaN	-1.157892
5	-1.344312	NaN	NaN
6	-0.109050	1.643563	NaN
7	0.357021	-0.674600	NaN
8	-0.968914	-1.294524	0.413738
9	0.276662	-0.472035	-0.013960

In [54]: `dff.fillna(dff.mean())`**Out[54]:**

	A	B	C
0	0.271860	-0.424972	0.567020
1	0.276232	-1.087401	-0.673690
2	0.113648	-1.478427	0.524988
3	-0.140857	0.577046	-1.715002
4	-0.140857	-0.401419	-1.157892
5	-1.344312	-0.401419	-0.293543
6	-0.109050	1.643563	-0.293543
7	0.357021	-0.674600	-0.293543
8	-0.968914	-1.294524	0.413738
9	0.276662	-0.472035	-0.013960

In [55]: `dff.fillna(dff.mean()["B": "C"])`**Out[55]:**

	A	B	C
0	0.271860	-0.424972	0.567020
1	0.276232	-1.087401	-0.673690
2	0.113648	-1.478427	0.524988
3	NaN	0.577046	-1.715002
4	NaN	-0.401419	-1.157892
5	-1.344312	-0.401419	-0.293543
6	-0.109050	1.643563	-0.293543
7	0.357021	-0.674600	-0.293543
8	-0.968914	-1.294524	0.413738
9	0.276662	-0.472035	-0.013960

Same result as above, but is aligning the ‘fill’ value which is a Series in this case.

In [56]: `dff.where(pd.notna(dff), dff.mean(), axis="columns")`**Out[56]:**

	A	B	C
0	0.271860	-0.424972	0.567020
1	0.276232	-1.087401	-0.673690
2	0.113648	-1.478427	0.524988

(continues on next page)

(continued from previous page)

6	-0.109050	1.643563	-0.293543
7	0.357021	-0.674600	-0.293543
8	-0.968914	-1.294524	0.413738
9	0.276662	-0.472035	-0.013960

2.10.8 Dropping axis labels with missing data: dropna

You may wish to simply exclude labels from a data set which refer to missing data. To do this, use `dropna()`:

```
In [57]: df
Out[57]:
   one      two      three
a  NaN -0.282863 -1.509059
c  NaN  1.212112 -0.173215
e  NaN  0.000000  0.000000
f  NaN  0.000000  0.000000
h  NaN -0.706771 -1.039575
```

```
In [58]: df.dropna(axis=0)
Out[58]:
Empty DataFrame
Columns: [one, two, three]
Index: []
```

```
In [59]: df.dropna(axis=1)
Out[59]:
      two      three
a -0.282863 -1.509059
c  1.212112 -0.173215
e  0.000000  0.000000
f  0.000000  0.000000
h -0.706771 -1.039575
```

```
In [60]: df["one"].dropna()
Out[60]: Series([], Name: one, dtype: float64)
```

An equivalent `dropna()` is available for Series. DataFrame.dropna has considerably more options than Series.dropna, which can be examined *in the API*.

2.10.9 Interpolation 线性插值, 线性填充

Both Series and DataFrame objects have `interpolate()` that, by default, performs linear interpolation at missing data points.

```
In [61]: ts
Out[61]:
2000-01-31    0.469112
2000-02-29      NaN
2000-03-31      NaN
2000-04-28      NaN
```

(continues on next page)

2007-12-31    -6.950267
2008-01-31    -7.904475
2008-02-29    -6.441779
2008-03-31    -8.184940
2008-04-30    -9.011531
Freq: BM, Length: 100, dtype: float64

```

In [65]: ts.interpolate().count()

Out[65]: 100

In [66]: ts.interpolate().plot()

Out[66]: <AxesSubplot:>

Index aware interpolation is available via the `method` keyword:

In [67]: ts2

Out[67]:

```

2000-01-31    0.469112
2000-02-29      NaN
2002-07-31   -5.785037
2005-01-31      NaN

```

(continues on next page)

(continued from previous page)

```
2008-04-30    -9.011531
dtype: float64
```

In [68]: ts2.interpolate()

Out[68]:

```
2000-01-31    0.469112
2000-02-29   -2.657962
2002-07-31   -5.785037
2005-01-31   -7.398284
2008-04-30   -9.011531
dtype: float64
```

In [69]: ts2.interpolate(method="time")

Out[69]:

```
2000-01-31    0.469112
2000-02-29    0.270241
2002-07-31   -5.785037
2005-01-31   -7.190866
2008-04-30   -9.011531
dtype: float64
```

For a floating-point index, use `method='values'`:

In [70]: ser

Out[70]:

```
0.0      0.0
1.0      NaN
10.0     10.0
dtype: float64
```

In [71]: ser.interpolate()

Out[71]:

```
0.0      0.0
1.0      5.0
10.0     10.0
dtype: float64
```

In [72]: ser.interpolate(method="values")

Out[72]:

```
0.0      0.0
1.0      1.0
10.0     10.0
dtype: float64
```

You can also interpolate with a DataFrame:

```
In [73]: df = pd.DataFrame(
.....:     {
.....:         "A": [1, 2.1, np.nan, 4.7, 5.6, 6.8],
.....:         "B": [0.25, np.nan, np.nan, 4, 12.2, 14.4],
.....:     }
.....: )
```

(continues on next page)

(continued from previous page)

```
....:

In [74]: df
Out[74]:
      A      B
0  1.0  0.25
1  2.1    NaN
2  NaN    NaN
3  4.7  4.00
4  5.6 12.20
5  6.8 14.40

In [75]: df.interpolate()
Out[75]:
      A      B
0  1.0  0.25
1  2.1  1.50
2  3.4  2.75
3  4.7  4.00
4  5.6 12.20
5  6.8 14.40
```

The `method` argument gives access to fancier interpolation methods. If you have `scipy` installed, you can pass the name of a 1-d interpolation routine to `method`. You'll want to consult the full `scipy` interpolation [documentation](#) and [reference guide](#) for details. The appropriate interpolation method will depend on the type of data you are working with.

- If you are dealing with a time series that is growing at an increasing rate, `method='quadratic'` may be appropriate.
- If you have values approximating a cumulative distribution function, then `method='pchip'` should work well.
- To fill missing values with goal of smooth plotting, consider `method='akima'`.

Warning: These methods require `scipy`.

```
In [76]: df.interpolate(method="barycentric")
Out[76]:
      A      B
0  1.00  0.250
1  2.10 -7.660
2  3.53 -4.515
3  4.70  4.000
4  5.60 12.200
5  6.80 14.400

In [77]: df.interpolate(method="pchip")
Out[77]:
      A      B
0  1.00000  0.250000
1  2.10000  0.672808
2  3.43454  1.928950
3  4.70000  4.000000
```

(continues on next page)

(continued from previous page)

```
4 5.60000 12.200000
5 6.80000 14.400000
```

In [78]: df.interpolate(method="akima")

Out[78]:

	A	B
0	1.000000	0.250000
1	2.100000	-0.873316
2	3.406667	0.320034
3	4.700000	4.000000
4	5.600000	12.200000
5	6.800000	14.400000

When interpolating via a polynomial or spline approximation, you must also specify the degree or order of the approximation:

In [79]: df.interpolate(method="spline", order=2)

Out[79]:

	A	B
0	1.000000	0.250000
1	2.100000	-0.428598
2	3.404545	1.206900
3	4.700000	4.000000
4	5.600000	12.200000
5	6.800000	14.400000

In [80]: df.interpolate(method="polynomial", order=2)

Out[80]:

	A	B
0	1.000000	0.250000
1	2.100000	-2.703846
2	3.451351	-1.453846
3	4.700000	4.000000
4	5.600000	12.200000
5	6.800000	14.400000

Compare several methods:

In [81]: np.random.seed(2)

In [82]: ser = pd.Series(np.arange(1, 10.1, 0.25) ** 2 + np.random.randn(37))

In [83]: missing = np.array([4, 13, 14, 15, 16, 17, 18, 20, 29])

In [84]: ser[missing] = np.nan

In [85]: methods = ["linear", "quadratic", "cubic"]

In [86]: df = pd.DataFrame({m: ser.interpolate(method=m) for m in methods})

In [87]: df.plot()

Out[87]: <AxesSubplot:>

Another use case is interpolation at *new* values. Suppose you have 100 observations from some distribution. And let's suppose that you're particularly interested in what's happening around the middle. You can mix pandas' `reindex` and `interpolate` methods to interpolate at the new values.

```
In [88]: ser = pd.Series(np.sort(np.random.uniform(size=100)))

# interpolate at new_index
In [89]: new_index = ser.index.union(pd.Index([49.25, 49.5, 49.75, 50.25, 50.5, 50.75]))

In [90]: interp_s = ser.reindex(new_index).interpolate(method="pchip")

In [91]: interp_s[49:51]
Out[91]:
49.00    0.471410
49.25    0.476841
49.50    0.481780
49.75    0.485998
50.00    0.489266
50.25    0.491814
50.50    0.493995
50.75    0.495763
51.00    0.497074
dtype: float64
```

Interpolation limits

Like other pandas fill methods, `interpolate()` accepts a `limit` keyword argument. Use this argument to limit the number of consecutive NaN values filled since the last valid observation:

```
In [92]: ser = pd.Series([np.nan, np.nan, 5, np.nan, np.nan, np.nan, 13, np.nan, np.nan])
```

```
In [93]: ser
```

```
Out[93]:
```

```
0      NaN  
1      NaN  
2      5.0  
3      NaN  
4      NaN  
5      NaN  
6     13.0  
7      NaN  
8      NaN  
dtype: float64
```

```
# fill all consecutive values in a forward direction
```

```
In [94]: ser.interpolate()
```

```
Out[94]:
```

```
0      NaN  
1      NaN  
2      5.0  
3      7.0  
4      9.0  
5     11.0  
6     13.0  
7     13.0  
8     13.0  
dtype: float64
```

```
# fill one consecutive value in a forward direction
```

```
In [95]: ser.interpolate(limit=1)
```

```
Out[95]:
```

```
0      NaN  
1      NaN  
2      5.0  
3      7.0  
4      NaN  
5      NaN  
6     13.0  
7     13.0  
8      NaN  
dtype: float64
```

By default, NaN values are filled in a forward direction. Use `limit_direction` parameter to fill backward or from both directions.

```
# fill one consecutive value backwards
```

```
In [96]: ser.interpolate(limit=1, limit_direction="backward")
```

```
Out[96]:
```

(continues on next page)

(continued from previous page)

```

0      NaN
1      5.0
2      5.0
3      NaN
4      NaN
5     11.0
6     13.0
7      NaN
8      NaN
dtype: float64

# fill one consecutive value in both directions
In [97]: ser.interpolate(limit=1, limit_direction="both")
Out[97]:
0      NaN
1      5.0
2      5.0
3      7.0
4      NaN
5     11.0
6     13.0
7     13.0
8      NaN
dtype: float64

# fill all consecutive values in both directions
In [98]: ser.interpolate(limit_direction="both")
Out[98]:
0      5.0
1      5.0
2      5.0
3      7.0
4      9.0
5     11.0
6     13.0
7     13.0
8     13.0
dtype: float64

```

By default, `NaN` values are filled whether they are inside (surrounded by) existing valid values, or outside existing valid values. The `limit_area` parameter restricts filling to either inside or outside values.

```

# fill one consecutive inside value in both directions
In [99]: ser.interpolate(limit_direction="both", limit_area="inside", limit=1)
Out[99]:
0      NaN
1      NaN
2      5.0
3      7.0
4      NaN
5     11.0
6     13.0

```

(continues on next page)

(continued from previous page)

```
7      NaN
8      NaN
dtype: float64

# fill all consecutive outside values backward
In [100]: ser.interpolate(limit_direction="backward", limit_area="outside")
Out[100]:
0    5.0
1    5.0
2    5.0
3    NaN
4    NaN
5    NaN
6   13.0
7    NaN
8    NaN
dtype: float64

# fill all consecutive outside values in both directions
In [101]: ser.interpolate(limit_direction="both", limit_area="outside")
Out[101]:
0    5.0
1    5.0
2    5.0
3    NaN
4    NaN
5    NaN
6   13.0
7   13.0
8   13.0
dtype: float64
```

2.10.10 Replacing generic values

Often times we want to replace arbitrary values with other values.

`replace()` in Series and `replace()` in DataFrame provides an efficient yet flexible way to perform such replacements.

For a Series, you can replace a single value or a list of values by another value:

```
In [102]: ser = pd.Series([0.0, 1.0, 2.0, 3.0, 4.0])

In [103]: ser.replace(0, 5)
Out[103]:
0    5.0
1    1.0
2    2.0
3    3.0
4    4.0
dtype: float64
```

You can replace a list of values by a list of other values:

```
In [104]: ser.replace([0, 1, 2, 3, 4], [4, 3, 2, 1, 0])
```

```
Out[104]:
```

```
0    4.0
1    3.0
2    2.0
3    1.0
4    0.0
dtype: float64
```

You can also specify a mapping dict:

```
In [105]: ser.replace({0: 10, 1: 100})
```

```
Out[105]:
```

```
0    10.0
1   100.0
2    2.0
3    3.0
4    4.0
dtype: float64
```

For a DataFrame, you can specify individual values by column:

```
In [106]: df = pd.DataFrame({"a": [0, 1, 2, 3, 4], "b": [5, 6, 7, 8, 9]})
```

```
In [107]: df.replace({"a": 0, "b": 5}, 100)
```

```
Out[107]:
```

	a	b
0	100	100
1	1	6
2	2	7
3	3	8
4	4	9

Instead of replacing with specified values, you can treat all given values as missing and interpolate over them:

```
In [108]: ser.replace([1, 2, 3], method="pad")
```

```
Out[108]:
```

```
0    0.0
1    0.0
2    0.0
3    0.0
4    4.0
dtype: float64
```

2.10.11 String/regular expression replacement

Note: Python strings prefixed with the `r` character such as `r'hello world'` are so-called “raw” strings. They have different semantics regarding backslashes than strings without this prefix. Backslashes in raw strings will be interpreted as an escaped backslash, e.g., `r'\' == '\\'`. You should [read about them](#) if this is unclear.

Replace the ‘.’ with `NaN` (`str -> str`):

```
In [109]: d = {"a": list(range(4)), "b": list("ab.."), "c": ["a", "b", np.nan, "d"]}
```

```
In [110]: df = pd.DataFrame(d)
```

```
In [111]: df.replace(".", np.nan)
```

Out[111]:

```
a    b    c  
0  0    a    a  
1  1    b    b  
2  2  NaN  NaN  
3  3  NaN    d
```

Now do it with a regular expression that removes surrounding whitespace (`regex -> regex`):

```
In [112]: df.replace(r"\s*\.\s*", np.nan, regex=True)
```

Out[112]:

```
a    b    c  
0  0    a    a  
1  1    b    b  
2  2  NaN  NaN  
3  3  NaN    d
```

Replace a few different values (`list -> list`):

```
In [113]: df.replace(["a", "."], ["b", np.nan])
```

Out[113]:

```
a    b    c  
0  0    b    b  
1  1    b    b  
2  2  NaN  NaN  
3  3  NaN    d
```

list of regex -> list of regex:

```
In [114]: df.replace([r"\.", r"(a)"], ["dot", r"\1stuff"], regex=True)
```

Out[114]:

```
a      b      c  
0  0  astuff  astuff  
1  1        b      b  
2  2      dot    NaN  
3  3      dot    d
```

Only search in column 'b' (`dict -> dict`):

```
In [115]: df.replace({"b": ".}, {"b": np.nan})
```

Out[115]:

	a	b	c
0	0	a	a
1	1	b	b
2	2	NaN	NaN
3	3	NaN	d

Same as the previous example, but use a regular expression for searching instead (dict of regex -> dict):

```
In [116]: df.replace({"b": r"\s*\.\s*"}, {"b": np.nan}, regex=True)
```

Out[116]:

	a	b	c
0	0	a	a
1	1	b	b
2	2	NaN	NaN
3	3	NaN	d

You can pass nested dictionaries of regular expressions that use `regex=True`:

```
In [117]: df.replace({"b": {"b": r"\s*"}, regex=True})
```

Out[117]:

	a	b	c
0	0	a	a
1	1		b
2	2	.	NaN
3	3	.	d

Alternatively, you can pass the nested dictionary like so:

```
In [118]: df.replace(regex={"b": {r"\s*\.\s*": np.nan}})
```

Out[118]:

	a	b	c
0	0	a	a
1	1	b	b
2	2	NaN	NaN
3	3	NaN	d

You can also use the group of a regular expression match when replacing (dict of regex -> dict of regex), this works for lists as well.

```
In [119]: df.replace({"b": r"\s*(\.)\s*", {"b": r"\1ty"}, regex=True})
```

Out[119]:

	a	b	c
0	0	a	a
1	1	b	b
2	2	.ty	NaN
3	3	.ty	d

You can pass a list of regular expressions, of which those that match will be replaced with a scalar (list of regex -> regex).

```
In [120]: df.replace([r"\s*\.\s*", r"a|b"], np.nan, regex=True)
```

Out[120]:

(continues on next page)

(continued from previous page)

	a	b	c
0	0	NaN	NaN
1	1	NaN	NaN
2	2	NaN	NaN
3	3	NaN	d

All of the regular expression examples can also be passed with the `to_replace` argument as the `regex` argument. In this case the `value` argument must be passed explicitly by name or `regex` must be a nested dictionary. The previous example, in this case, would then be:

```
In [121]: df.replace(regex=[r"\s*\.\s*", r"a|b"], value=np.nan)
```

```
Out[121]:
```

	a	b	c
0	0	NaN	NaN
1	1	NaN	NaN
2	2	NaN	NaN
3	3	NaN	d

This can be convenient if you do not want to pass `regex=True` every time you want to use a regular expression.

Note: Anywhere in the above `replace` examples that you see a regular expression a compiled regular expression is valid as well.

2.10.12 Numeric replacement

`replace()` is similar to `fillna()`.

```
In [122]: df = pd.DataFrame(np.random.randn(10, 2))
```

```
In [123]: df[np.random.rand(df.shape[0]) > 0.5] = 1.5
```

```
In [124]: df.replace(1.5, np.nan)
```

```
Out[124]:
```

	0	1
0	-0.844214	-1.021415
1	0.432396	-0.323580
2	0.423825	0.799180
3	1.262614	0.751965
4	NaN	NaN
5	NaN	NaN
6	-0.498174	-1.060799
7	0.591667	-0.183257
8	1.019855	-1.482465
9	NaN	NaN

Replacing more than one value is possible by passing a list.

```
In [125]: df00 = df.iloc[0, 0]
```

```
In [126]: df.replace([1.5, df00], [np.nan, "a"])
```

(continues on next page)

(continued from previous page)

Out[126]:

	0	1
0	a	-1.021415
1	0.432396	-0.323580
2	0.423825	0.799180
3	1.262614	0.751965
4	NaN	NaN
5	NaN	NaN
6	-0.498174	-1.060799
7	0.591667	-0.183257
8	1.019855	-1.482465
9	NaN	NaN

In [127]: df[1].dtype**Out[127]:** dtype('float64')

You can also operate on the DataFrame in place:

In [128]: df.replace(1.5, np.nan, inplace=True)

Missing data casting rules and indexing

While pandas supports storing arrays of integer and boolean type, these types are not capable of storing missing data. Until we can switch to using a native NA type in NumPy, we've established some "casting rules". When a reindexing operation introduces missing data, the Series will be cast according to the rules introduced in the table below.

data type	Cast to
integer	float
boolean	object
float	no cast
object	no cast

For example:

In [129]: s = pd.Series(np.random.randn(5), index=[0, 2, 4, 6, 7])**In [130]:** s > 0**Out[130]:**

0	True
2	True
4	True
6	True
7	True

In [131]: (s > 0).dtype**Out[131]:** dtype('bool')**In [132]:** crit = (s > 0).reindex(list(range(8)))

(continues on next page)

(continued from previous page)

In [133]: crit**Out[133]:**

```
0    True
1    NaN
2    True
3    NaN
4    True
5    NaN
6    True
7    True
dtype: object
```

In [134]: crit.dtype**Out[134]:** dtype('O')

Ordinarily NumPy will complain if you try to use an object array (even if it contains boolean values) instead of a boolean array to get or set values from an ndarray (e.g. selecting values based on some criteria). If a boolean vector contains NAs, an exception will be generated:

In [135]: reindexed = s.reindex(list(range(8))).fillna(0)**In [136]:** reindexed[crit]

```
ValueError                                                 Traceback (most recent call last)
Input In [136], in <module>
----> 1 reindexed[crit]
```

```
File /pandas/pandas/core/series.py:979, in Series.__getitem__(self, key)
 976     if is_iterator(key):
 977         key = list(key)
--> 979     if com.is_bool_indexer(key):
 980         key = check_bool_indexer(self.index, key)
 981     key = np.asarray(key, dtype=bool)
```

```
File /pandas/pandas/core/common.py:144, in is_bool_indexer(key)
140     na_msg = "Cannot mask with non-boolean array containing NA / NaN values"
141     if lib.infer_dtype(key) == "boolean" and isna(key).any():
142         # Don't raise on e.g. ["A", "B", np.nan], see
143         # test_loc_getitem_list_of_labels_categorical_index_with_na
--> 144         raise ValueError(na_msg)
145     return False
146 return True
```

```
ValueError: Cannot mask with non-boolean array containing NA / NaN values
```

However, these can be filled in using `fillna()` and it will work fine:

In [137]: reindexed[crit.fillna(False)]**Out[137]:**

```
0    0.126504
2    0.696198
4    0.697416
```

(continues on next page)

(continued from previous page)

```
6    0.601516
7    0.003659
dtype: float64
```

In [138]: reindexed[crit.fillna(**True**)]

Out[138]:

```
0    0.126504
1    0.000000
2    0.696198
3    0.000000
4    0.697416
5    0.000000
6    0.601516
7    0.003659
dtype: float64
```

pandas provides a nullable integer dtype, but you must explicitly request it when creating the series or column. Notice that we use a capital “I” in the `dtype="Int64"`.

In [139]: s = pd.Series([**0**, **1**, np.nan, **3**, **4**], dtype="Int64")

In [140]: s

Out[140]:

```
0      0
1      1
2    <NA>
3      3
4      4
dtype: Int64
```

See [Nullable integer data type](#) for more.

2.10.13 Experimental NA scalar to denote missing values

Warning: Experimental: the behaviour of `pd.NA` can still change without warning.

New in version 1.0.0.

Starting from pandas 1.0, an experimental `pd.NA` value (singleton) is available to represent scalar missing values. At this moment, it is used in the nullable [integer](#), boolean and [dedicated string](#) data types as the missing value indicator.

The goal of `pd.NA` is provide a “missing” indicator that can be used consistently across data types (instead of `np.nan`, `None` or `pd.NaT` depending on the data type).

For example, when having missing values in a Series with the nullable integer dtype, it will use `pd.NA`:

In [141]: s = pd.Series([**1**, **2**, **None**], dtype="Int64")

In [142]: s

Out[142]:

```
0      1
```

(continues on next page)

(continued from previous page)

```
1      2
2    <NA>
dtype: Int64
```

In [143]: s[2]

Out[143]: <NA>

In [144]: s[2] **is** pd.NA

Out[144]: True

Currently, pandas does not yet use those data types by default (when creating a DataFrame or Series, or when reading in data), so you need to specify the dtype explicitly. An easy way to convert to those dtypes is explained [here](#).

Propagation in arithmetic and comparison operations

In general, missing values *propagate* in operations involving pd.NA. When one of the operands is unknown, the outcome of the operation is also unknown.

For example, pd.NA propagates in arithmetic operations, similarly to np.nan:

In [145]: pd.NA + 1

Out[145]: <NA>

In [146]: "a" * pd.NA

Out[146]: <NA>

There are a few special cases when the result is known, even when one of the operands is NA.

In [147]: pd.NA ** 0

Out[147]: 1

In [148]: 1 ** pd.NA

Out[148]: 1

In equality and comparison operations, pd.NA also propagates. This deviates from the behaviour of np.nan, where comparisons with np.nan always return False.

In [149]: pd.NA == 1

Out[149]: <NA>

In [150]: pd.NA == pd.NA

Out[150]: <NA>

In [151]: pd.NA < 2.5

Out[151]: <NA>

To check if a value is equal to pd.NA, the `isna()` function can be used:

In [152]: pd.isna(pd.NA)

Out[152]: True

An exception on this basic propagation rule are *reductions* (such as the mean or the minimum), where pandas defaults to skipping missing values. See [above](#) for more.

Logical operations

For logical operations, `pd.NA` follows the rules of the [three-valued logic](#) (or *Kleene logic*, similarly to R, SQL and Julia). This logic means to only propagate missing values when it is logically required.

For example, for the logical “or” operation (`|`), if one of the operands is `True`, we already know the result will be `True`, regardless of the other value (so regardless the missing value would be `True` or `False`). In this case, `pd.NA` does not propagate:

```
In [153]: True | False
Out[153]: True
```

```
In [154]: True | pd.NA
Out[154]: True
```

```
In [155]: pd.NA | True
Out[155]: True
```

On the other hand, if one of the operands is `False`, the result depends on the value of the other operand. Therefore, in this case `pd.NA` propagates:

```
In [156]: False | True
Out[156]: True
```

```
In [157]: False | False
Out[157]: False
```

```
In [158]: False | pd.NA
Out[158]: <NA>
```

The behaviour of the logical “and” operation (`&`) can be derived using similar logic (where now `pd.NA` will not propagate if one of the operands is already `False`):

```
In [159]: False & True
Out[159]: False
```

```
In [160]: False & False
Out[160]: False
```

```
In [161]: False & pd.NA
Out[161]: False
```

```
In [162]: True & True
Out[162]: True
```

```
In [163]: True & False
Out[163]: False
```

```
In [164]: True & pd.NA
Out[164]: <NA>
```

NA in a boolean context

Since the actual value of an NA is unknown, it is ambiguous to convert NA to a boolean value. The following raises an error:

```
In [165]: bool(pd.NA)

TypeError                                 Traceback (most recent call last)
Input In [165], in <module>
----> 1 bool(pd.NA)

File /pandas/pandas/_libs/missing.pyx:382, in pandas._libs.missing.NAType.__bool__()

TypeError: boolean value of NA is ambiguous
```

This also means that pd.NA cannot be used in a context where it is evaluated to a boolean, such as `if condition: ...` where `condition` can potentially be pd.NA. In such cases, `isna()` can be used to check for pd.NA or condition being pd.NA can be avoided, for example by filling missing values beforehand.

A similar situation occurs when using Series or DataFrame objects in `if` statements, see *Using if/truth statements with pandas*.

NumPy ufuncs

`pandas.NA` implements NumPy's `__array_ufunc__` protocol. Most ufuncs work with NA, and generally return NA:

```
In [166]: np.log(pd.NA)
Out[166]: <NA>

In [167]: np.add(pd.NA, 1)
Out[167]: <NA>
```

Warning: Currently, ufuncs involving an ndarray and NA will return an object-dtype filled with NA values.

```
In [168]: a = np.array([1, 2, 3])

In [169]: np.greater(a, pd.NA)
Out[169]: array([<NA>, <NA>, <NA>], dtype=object)
```

The return type here may change to return a different array type in the future.

See *DataFrame interoperability with NumPy functions* for more on ufuncs.

Conversion

If you have a DataFrame or Series using traditional types that have missing data represented using `np.nan`, there are convenience methods `convert_dtypes()` in Series and `convert_dtypes()` in DataFrame that can convert data to use the newer dtypes for integers, strings and booleans listed [here](#). This is especially helpful after reading in data sets when letting the readers such as `read_csv()` and `read_excel()` infer default dtypes.

In this example, while the dtypes of all columns are changed, we show the results for the first 10 columns.

```
In [170]: bb = pd.read_csv("data/baseball.csv", index_col="id")
```

```
In [171]: bb[bb.columns[:10]].dtypes
```

```
Out[171]:
```

player	object
year	int64
stint	int64
team	object
lg	object
g	int64
ab	int64
r	int64
h	int64
X2b	int64
dtype:	object

```
In [172]: bbn = bb.convert_dtypes()
```

```
In [173]: bbn[bbn.columns[:10]].dtypes
```

```
Out[173]:
```

player	string
year	Int64
stint	Int64
team	string
lg	string
g	Int64
ab	Int64
r	Int64
h	Int64
X2b	Int64
dtype:	object

2.11 Duplicate Labels

Index objects are not required to be unique; you can have duplicate row or column labels. This may be a bit confusing at first. If you're familiar with SQL, you know that row labels are similar to a primary key on a table, and you would never want duplicates in a SQL table. But one of pandas' roles is to clean messy, real-world data before it goes to some downstream system. And real-world data has duplicates, even in fields that are supposed to be unique.

This section describes how duplicate labels change the behavior of certain operations, and how prevent duplicates from arising during operations, or to detect them if they do.

```
In [1]: import pandas as pd  
  
In [2]: import numpy as np
```

2.11.1 Consequences of Duplicate Labels

Some pandas methods (Series.reindex() for example) just don't work with duplicates present. The output can't be determined, and so pandas raises.

```
In [3]: s1 = pd.Series([0, 1, 2], index=["a", "b", "b"])  
  
In [4]: s1.reindex(["a", "b", "c"])  
-----  
ValueError Traceback (most recent call last)  
Input In [4], in <module>  
----> 1 s1.reindex(["a", "b", "c"])  
  
File /pandas/pandas/core/series.py:4672, in Series.reindex(self, *args, **kwargs)  
 4668     raise TypeError(  
 4669         "'index' passed as both positional and keyword argument"  
 4670     )  
 4671     kwargs.update({"index": index})  
-> 4672 return super().reindex(**kwargs)  
  
File /pandas/pandas/core/generic.py:4974, in NDFrame.reindex(self, *args, **kwargs)  
 4971     return self._reindex_multi(axes, copy, fill_value)  
 4973 # perform the reindex on the axes  
-> 4974 return self._reindex_axes(  
 4975     axes, level, limit, tolerance, method, fill_value, copy  
 4976 ).__finalize__(self, method="reindex")  
  
File /pandas/pandas/core/generic.py:4994, in NDFrame._reindex_axes(self, axes, level,   
-> limit, tolerance, method, fill_value, copy)  
 4989 new_index, indexer = ax.reindex(  
 4990     labels, level=level, limit=limit, tolerance=tolerance, method=method  
 4991 )  
 4993 axis = self._get_axis_number(a)  
-> 4994 obj = obj._reindex_with_indexers(  
 4995     {axis: [new_index, indexer]},  
 4996     fill_value=fill_value,  
 4997     copy=copy,  
 4998     allow_dups=False,  
 4999 )  
 5000 # If we've made a copy once, no need to make another one  
 5001 copy = False  
  
File /pandas/pandas/core/generic.py:5040, in NDFrame._reindex_with_indexers(self,   
-> reindexers, fill_value, copy, allow_dups)  
 5037     indexer = ensure_platform_int(indexer)  
 5039 # TODO: speed up on homogeneous DataFrame objects (see _reindex_multi)  
-> 5040 new_data = new_data.reindex_indexer()
```

(continues on next page)

(continued from previous page)

```

5041     index,
5042     indexer,
5043     axis=baxis,
5044     fill_value=fill_value,
5045     allow_dups=allow_dups,
5046     copy=copy,
5047 )
5048 # If we've made a copy once, no need to make another one
5049 copy = False

File /pandas/pandas/core/internals/managers.py:679, in BaseBlockManager.reindex_
→ indexer(self, new_axis, indexer, axis, fill_value, allow_dups, copy, consolidate, only_
→ slice, use_na_proxy)
    677 # some axes don't allow reindexing with dups
    678 if not allow_dups:
--> 679     self.axes[axis]._validate_can_reindex(indexer)
    681 if axis >= self.ndim:
    682     raise IndexError("Requested axis not found in manager")

File /pandas/pandas/core/indexes/base.py:4107, in Index._validate_can_reindex(self,_
→ indexer)
    4105 # trying to reindex on an axis with duplicates
    4106 if not self._index_as_unique and len(indexer):
-> 4107     raise ValueError("cannot reindex on an axis with duplicate labels")

ValueError: cannot reindex on an axis with duplicate labels

```

Other methods, like indexing, can give very surprising results. Typically indexing with a scalar will *reduce dimensionality*. Slicing a DataFrame with a scalar will return a Series. Slicing a Series with a scalar will return a scalar. But with duplicates, this isn't the case.

```

In [5]: df1 = pd.DataFrame([[0, 1, 2], [3, 4, 5]], columns=["A", "A", "B"])

In [6]: df1
Out[6]:
   A   A   B
0  0   1   2
1  3   4   5

```

We have duplicates in the columns. If we slice 'B', we get back a Series

```

In [7]: df1["B"]  # a series
Out[7]:
0    2
1    5
Name: B, dtype: int64

```

But slicing 'A' returns a DataFrame

```

In [8]: df1["A"]  # a DataFrame
Out[8]:
   A   A

```

(continues on next page)

(continued from previous page)

```
0  0  1  
1  3  4
```

This applies to row labels as well

```
In [9]: df2 = pd.DataFrame({ "A": [0, 1, 2]}, index=["a", "a", "b"])
```

```
In [10]: df2
```

```
Out[10]:
```

```
      A  
a  0  
a  1  
b  2
```

```
In [11]: df2.loc["b", "A"] # a scalar
```

```
Out[11]: 2
```

```
In [12]: df2.loc["a", "A"] # a Series
```

```
Out[12]:
```

```
a    0  
a    1  
Name: A, dtype: int64
```

2.11.2 Duplicate Label Detection

You can check whether an `Index` (storing the row or column labels) is unique with `Index.is_unique`:

```
In [13]: df2
```

```
Out[13]:
```

```
      A  
a  0  
a  1  
b  2
```

```
In [14]: df2.index.is_unique
```

```
Out[14]: False
```

```
In [15]: df2.columns.is_unique
```

```
Out[15]: True
```

Note: Checking whether an index is unique is somewhat expensive for large datasets. pandas does cache this result, so re-checking on the same index is very fast.

`Index.duplicated()` will return a boolean ndarray indicating whether a label is repeated.

```
In [16]: df2.index.duplicated()
```

```
Out[16]: array([False,  True, False])
```

Which can be used as a boolean filter to drop duplicate rows.

```
In [17]: df2.loc[~df2.index.duplicated(), :]
```

```
Out[17]:
```

```
A  
a 0  
b 2
```

If you need additional logic to handle duplicate labels, rather than just dropping the repeats, using `groupby()` on the index is a common trick. For example, we'll resolve duplicates by taking the average of all rows with the same label.

```
In [18]: df2.groupby(level=0).mean()
```

```
Out[18]:
```

```
A  
a 0.5  
b 2.0
```

2.11.3 Disallowing Duplicate Labels

New in version 1.2.0.

As noted above, handling duplicates is an important feature when reading in raw data. That said, you may want to avoid introducing duplicates as part of a data processing pipeline (from methods like `pandas.concat()`, `rename()`, etc.). Both Series and DataFrame *disallow* duplicate labels by calling `.set_flags(allow_duplicate_labels=False)`. (the default is to allow them). If there are duplicate labels, an exception will be raised.

```
In [19]: pd.Series([0, 1, 2], index=["a", "b", "b"]).set_flags(allow_duplicate_labels=False)
```

```
DuplicateLabelError Traceback (most recent call last)
```

```
Input In [19], in <module>
```

```
----> 1 pd.Series([0, 1, 2], index=["a", "b", "b"]).set_flags(allow_duplicate_labels=False)
```

```
File /pandas/pandas/core/generic.py:438, in NDFrame.set_flags(self, copy, allow_duplicate_labels)
```

```
436 df = self.copy(deep=copy)
```

```
437 if allow_duplicate_labels is not None:
```

```
--> 438     df.flags["allow_duplicate_labels"] = allow_duplicate_labels
439 return df
```

```
File /pandas/pandas/core/flags.py:105, in Flags.__setitem__(self, key, value)
```

```
103 if key not in self._keys:
```

```
104     raise ValueError(f"Unknown flag {key}. Must be one of {self._keys}")
```

```
--> 105 setattr(self, key, value)
```

```
File /pandas/pandas/core/flags.py:92, in Flags.allow_duplicate_labels(self, value)
```

```
90 if not value:
```

```
91     for ax in obj.axes:
```

```
--> 92         ax._maybe_check_unique()
```

```
94 self._allow_duplicate_labels = value
```

```
File /pandas/pandas/core/indexes/base.py:715, in Index._maybe_check_unique(self)
```

(continues on next page)

(continued from previous page)

```

712 duplicates = self._format_duplicate_message()
713 msg += f"\n{duplicates}"
--> 715 raise DuplicateLabelError(msg)

DuplicateLabelError: Index has duplicates.
    positions
label
b      [1, 2]

```

This applies to both row and column labels for a DataFrame

```

In [20]: pd.DataFrame([[0, 1, 2], [3, 4, 5]], columns=["A", "B", "C"],).set_flags(
.....:     allows_duplicate_labels=False
.....: )
.....:
Out[20]:
   A   B   C
0  0  1  2
1  3  4  5

```

This attribute can be checked or set with `allows_duplicate_labels`, which indicates whether that object can have duplicate labels.

```

In [21]: df = pd.DataFrame({"A": [0, 1, 2, 3]}, index=["x", "y", "X", "Y"]).set_flags(
.....:     allows_duplicate_labels=False
.....: )
.....:

In [22]: df
Out[22]:
   A
x  0
y  1
X  2
Y  3

In [23]: df.flags.allows_duplicate_labels
Out[23]: False

```

`DataFrame.set_flags()` can be used to return a new DataFrame with attributes like `allows_duplicate_labels` set to some value

```

In [24]: df2 = df.set_flags(allows_duplicate_labels=True)

In [25]: df2.flags.allows_duplicate_labels
Out[25]: True

```

The new DataFrame returned is a view on the same data as the old DataFrame. Or the property can just be set directly on the same object

```
In [26]: df2.flags.allows_duplicate_labels = False
```

(continues on next page)

(continued from previous page)

In [27]: df2.flags.allow_duplicates
Out[27]: False

When processing raw, messy data you might initially read in the messy data (which potentially has duplicate labels), deduplicate, and then disallow duplicates going forward, to ensure that your data pipeline doesn't introduce duplicates.

```
>>> raw = pd.read_csv("...")  

>>> deduplicated = raw.groupby(level=0).first() # remove duplicates  

>>> deduplicated.flags.allow_duplicates = False # disallow going forward
```

Setting `allow_duplicates=True` on a Series or DataFrame with duplicate labels or performing an operation that introduces duplicate labels on a Series or DataFrame that disallows duplicates will raise an `errors.DuplicateLabelError`.

```
In [28]: df.rename(str.upper)

DuplicateLabelError                                     Traceback (most recent call last)
Input In [28], in <module>

label
X      [0, 2]
Y      [1, 3]

```

This error message contains the labels that are duplicated, and the numeric positions of all the duplicates (including the “original”) in the Series or DataFrame

Duplicate Label Propagation

In general, disallowing duplicates is “sticky”. It’s preserved through operations.

```

In [29]: s1 = pd.Series([0, index=["a", "b"]].set_flags(allows_duplicate_labels=False))

In [30]: s1
Out[30]:
a    0
b    0
dtype: int64

In [31]: s1.head().rename({"a": "b"})

DuplicateLabelError                                     Traceback (most recent call last)
Input In [31], in <module>
----> 1 s1.head().rename({"a": "b"})

File /pandas/pandas/core/series.py:4601, in Series.rename(self, index, axis, copy, ↴
inplace, level, errors)
    4598     axis = self._get_axis_number(axis)
    4600     if callable(index) or is_dict_like(index):
-> 4601         return super().__rename__(
    4602             index, copy=copy, inplace=inplace, level=level, errors=errors
    4603         )

```

(continues on next page)

(continued from previous page)

```

4604 else:
4605     return self._set_name(index, inplace=inplace)

File /pandas/pandas/core/generic.py:1171, in NDFrame._rename(self, mapper, index,_
columns, axis, copy, inplace, level, errors)
1169     return None
1170 else:
-> 1171     return result.__finalize__(self, method="rename")

File /pandas/pandas/core/generic.py:5549, in NDFrame.__finalize__(self, other, method,_
**kwargs)
5546 for name in other.attrs:
5547     self.attrs[name] = other.attrs[name]
-> 5549 self.flags.allows_duplicate_labels = other.flags.allows_duplicate_labels
5550 # For subclasses using _metadata.
5551 for name in set(self._metadata) & set(other._metadata):

File /pandas/pandas/core	flags.py:92, in Flags.allows_duplicate_labels(self, value)
90 if not value:
91     for ax in obj.axes:
---> 92         ax._maybe_check_unique()
94 self._allows_duplicate_labels = value

File /pandas/pandas/core/indexes/base.py:715, in Index._maybe_check_unique(self)
712 duplicates = self._format_duplicate_message()
713 msg += f"\n{duplicates}"
--> 715 raise DuplicateLabelError(msg)

DuplicateLabelError: Index has duplicates.
    positions
label
b      [0, 1]

```

Warning: This is an experimental feature. Currently, many methods fail to propagate the `allows_duplicate_labels` value. In future versions it is expected that every method taking or returning one or more DataFrame or Series objects will propagate `allows_duplicate_labels`.

2.12 Categorical data

This is an introduction to pandas categorical data type, including a short comparison with R’s `factor`.

Categoricals are a pandas data type corresponding to categorical variables in statistics. A categorical variable takes on a limited, and usually fixed, number of possible values (`categories`; `levels` in R). Examples are gender, social class, blood type, country affiliation, observation time or rating via Likert scales.

In contrast to statistical categorical variables, categorical data might have an order (e.g. ‘strongly agree’ vs ‘agree’ or ‘first observation’ vs. ‘second observation’), but numerical operations (additions, divisions, ...) are not possible.

All values of categorical data are either in `categories` or `np.nan`. Order is defined by the order of `categories`, not lexical order of the values. Internally, the data structure consists of a `categories` array and an integer array of `codes` which point to the real value in the `categories` array.

The categorical data type is useful in the following cases:

- A string variable consisting of only a few different values. Converting such a string variable to a categorical variable will save some memory, see [here](#).
- The lexical order of a variable is not the same as the logical order (“one”, “two”, “three”). By converting to a categorical and specifying an order on the categories, sorting and min/max will use the logical order instead of the lexical order, see [here](#).
- As a signal to other Python libraries that this column should be treated as a categorical variable (e.g. to use suitable statistical methods or plot types).

See also the [API docs on categoricals](#).

2.12.1 Object creation

Series creation

Categorical Series or columns in a DataFrame can be created in several ways:

By specifying `dtype="category"` when constructing a Series:

```
In [1]: s = pd.Series(["a", "b", "c", "a"], dtype="category")  
  
In [2]: s  
Out[2]:  
0    a  
1    b  
2    c  
3    a  
dtype: category  
Categories (3, object): ['a', 'b', 'c']
```

By converting an existing Series or column to a `category` dtype:

```
In [3]: df = pd.DataFrame({"A": ["a", "b", "c", "a"]})  
  
In [4]: df["B"] = df["A"].astype("category")  
  
In [5]: df  
Out[5]:  
      A    B  
0   a    a  
1   b    b  
2   c    c  
3   a    a
```

By using special functions, such as `cut()`, which groups data into discrete bins. See the [example on tiling](#) in the docs.

```
In [6]: df = pd.DataFrame({"value": np.random.randint(0, 100, 20)})  
  
In [7]: labels = ["{} - {}".format(i, i + 9) for i in range(0, 100, 10)]  
  
In [8]: df["group"] = pd.cut(df.value, range(0, 105, 10), right=False, labels=labels)
```

(continues on next page)

(continued from previous page)

In [9]: df.head(10)**Out[9]:**

	value	group
0	65	60 - 69
1	49	40 - 49
2	56	50 - 59
3	43	40 - 49
4	43	40 - 49
5	91	90 - 99
6	32	30 - 39
7	87	80 - 89
8	36	30 - 39
9	8	0 - 9

By passing a `pandas.Categorical` object to a Series or assigning it to a DataFrame.**In [10]:** raw_cat = pd.Categorical(

.....: ["a", "b", "c", "a"], categories=["b", "c", "d"], ordered=False

.....:)

.....:

In [11]: s = pd.Series(raw_cat)**In [12]:** s**Out[12]:**

0	NaN
1	b
2	c
3	NaN

dtype: category
Categories (3, object): ['b', 'c', 'd']

In [13]: df = pd.DataFrame({"A": ["a", "b", "c", "a"]})**In [14]:** df["B"] = raw_cat**In [15]:** df**Out[15]:**

	A	B
0	a	NaN
1	b	b
2	c	c
3	a	NaN

Categorical data has a specific `category dtype`:**In [16]:** df.dtypes**Out[16]:**

A	object
B	category
dtype:	object

DataFrame creation

Similar to the previous section where a single column was converted to categorical, all columns in a DataFrame can be batch converted to categorical either during or after construction.

This can be done during construction by specifying `dtype="category"` in the `DataFrame` constructor:

```
In [17]: df = pd.DataFrame({"A": list("abca"), "B": list("bccd")}, dtype="category")
```

```
In [18]: df.dtypes
```

```
Out[18]:
```

```
A    category  
B    category  
dtype: object
```

Note that the categories present in each column differ; the conversion is done column by column, so only labels present in a given column are categories:

```
In [19]: df["A"]
```

```
Out[19]:
```

```
0    a  
1    b  
2    c  
3    a  
Name: A, dtype: category  
Categories (3, object): ['a', 'b', 'c']
```

```
In [20]: df["B"]
```

```
Out[20]:
```

```
0    b  
1    c  
2    c  
3    d  
Name: B, dtype: category  
Categories (3, object): ['b', 'c', 'd']
```

Analogously, all columns in an existing DataFrame can be batch converted using `DataFrame.astype()`:

```
In [21]: df = pd.DataFrame({"A": list("abca"), "B": list("bccd")})
```

```
In [22]: df_cat = df.astype("category")
```

```
In [23]: df_cat.dtypes
```

```
Out[23]:
```

```
A    category  
B    category  
dtype: object
```

This conversion is likewise done column by column:

```
In [24]: df_cat["A"]
```

```
Out[24]:
```

```
0    a  
1    b
```

(continues on next page)

(continued from previous page)

```

2    c
3    a
Name: A, dtype: category
Categories (3, object): ['a', 'b', 'c']

In [25]: df_cat["B"]
Out[25]:
0    b
1    c
2    c
3    d
Name: B, dtype: category
Categories (3, object): ['b', 'c', 'd']

```

Controlling behavior

In the examples above where we passed `dtype='category'`, we used the default behavior:

1. Categories are inferred from the data.
2. Categories are unordered.

To control those behaviors, instead of passing '`category`', use an instance of `CategoricalDtype`.

```

In [26]: from pandas.api.types import CategoricalDtype

In [27]: s = pd.Series(["a", "b", "c", "a"])

In [28]: cat_type = CategoricalDtype(categories=["b", "c", "d"], ordered=True)

In [29]: s_cat = s.astype(cat_type)

In [30]: s_cat
Out[30]:
0      NaN
1        b
2        c
3      NaN
dtype: category
Categories (3, object): ['b' < 'c' < 'd']

```

Similarly, a `CategoricalDtype` can be used with a `DataFrame` to ensure that categories are consistent among all columns.

```

In [31]: from pandas.api.types import CategoricalDtype

In [32]: df = pd.DataFrame({"A": list("abca"), "B": list("bccd")})

In [33]: cat_type = CategoricalDtype(categories=list("abcd"), ordered=True)

In [34]: df_cat = df.astype(cat_type)

In [35]: df_cat["A"]

```

(continues on next page)

(continued from previous page)

Out[35]:

```
0    a
1    b
2    c
3    a
Name: A, dtype: category
Categories (4, object): ['a' < 'b' < 'c' < 'd']
```

In [36]: df_cat["B"]**Out[36]:**

```
0    b
1    c
2    c
3    d
Name: B, dtype: category
Categories (4, object): ['a' < 'b' < 'c' < 'd']
```

Note: To perform table-wise conversion, where all labels in the entire DataFrame are used as categories for each column, the `categories` parameter can be determined programmatically by `categories = pd.unique(df.to_numpy().ravel())`.

If you already have codes and categories, you can use the `from_codes()` constructor to save the factorize step during normal constructor mode:

In [37]: splitter = np.random.choice([0, 1], 5, p=[0.5, 0.5])**In [38]:** s = pd.Series(pd.Categorical.from_codes(splitter, categories=["train", "test"]))

Regaining original data

To get back to the original Series or NumPy array, use `Series.astype(original_dtype)` or `np.asarray(categorical)`:

In [39]: s = pd.Series(["a", "b", "c", "a"])**In [40]:** s**Out[40]:**

```
0    a
1    b
2    c
3    a
dtype: object
```

In [41]: s2 = s.astype("category")**In [42]:** s2**Out[42]:**

```
0    a
1    b
2    c
```

(continues on next page)

(continued from previous page)

```

3    a
dtype: category
Categories (3, object): ['a', 'b', 'c']

In [43]: s2.astype(str)
Out[43]:
0    a
1    b
2    c
3    a
dtype: object

In [44]: np.asarray(s2)
Out[44]: array(['a', 'b', 'c', 'a'], dtype=object)

```

Note: In contrast to R's `factor` function, categorical data is not converting input values to strings; categories will end up the same data type as the original values.

Note: In contrast to R's `factor` function, there is currently no way to assign/change labels at creation time. Use `categories` to change the categories after creation time.

2.12.2 CategoricalDtype

A categorical's type is fully described by

1. `categories`: a sequence of unique values and no missing values
2. `ordered`: a boolean

This information can be stored in a `CategoricalDtype`. The `categories` argument is optional, which implies that the actual categories should be inferred from whatever is present in the data when the `pandas.Categorical` is created. The categories are assumed to be unordered by default.

```

In [45]: from pandas.api.types import CategoricalDtype

In [46]: CategoricalDtype(["a", "b", "c"])
Out[46]: CategoricalDtype(categories=['a', 'b', 'c'], ordered=False)

In [47]: CategoricalDtype(["a", "b", "c"], ordered=True)
Out[47]: CategoricalDtype(categories=['a', 'b', 'c'], ordered=True)

In [48]: CategoricalDtype()
Out[48]: CategoricalDtype(categories=None, ordered=False)

```

A `CategoricalDtype` can be used in any place pandas expects a `dtype`. For example `pandas.read_csv()`, `pandas.DataFrame.astype()`, or in the `Series` constructor.

Note: As a convenience, you can use the string '`category`' in place of a `CategoricalDtype` when you want the default behavior of the categories being unordered, and equal to the set values present in the array. In other words,

`dtype='category'` is equivalent to `dtype=CategoricalDtype()`.

Equality semantics

Two instances of `CategoricalDtype` compare equal whenever they have the same categories and order. When comparing two unordered categoricals, the order of the `categories` is not considered.

```
In [49]: c1 = CategoricalDtype(["a", "b", "c"], ordered=False)

# Equal, since order is not considered when ordered=False
In [50]: c1 == CategoricalDtype(["b", "c", "a"], ordered=False)
Out[50]: True

# Unequal, since the second CategoricalDtype is ordered
In [51]: c1 == CategoricalDtype(["a", "b", "c"], ordered=True)
Out[51]: False
```

All instances of `CategoricalDtype` compare equal to the string '`category`'.

```
In [52]: c1 == "category"
Out[52]: True
```

Warning: Since `dtype='category'` is essentially `CategoricalDtype(None, False)`, and since all instances `CategoricalDtype` compare equal to '`category`', all instances of `CategoricalDtype` compare equal to a `CategoricalDtype(None, False)`, regardless of `categories` or `ordered`.

2.12.3 Description

Using `describe()` on categorical data will produce similar output to a `Series` or `DataFrame` of type `string`.

```
In [53]: cat = pd.Categorical(["a", "c", "c", np.nan], categories=["b", "a", "c"])

In [54]: df = pd.DataFrame({"cat": cat, "s": ["a", "c", "c", np.nan]})

In [55]: df.describe()
Out[55]:
   cat    s
count    3    3
unique   2    2
top      c    c
freq     2    2

In [56]: df["cat"].describe()
Out[56]:
count    3
unique   2
top      c
freq     2
Name: cat, dtype: object
```

2.12.4 Working with categories

Categorical data has a `categories` and a `ordered` property, which list their possible values and whether the ordering matters or not. These properties are exposed as `s.cat.categories` and `s.cat.ordered`. If you don't manually specify categories and ordering, they are inferred from the passed arguments.

```
In [57]: s = pd.Series(["a", "b", "c", "a"], dtype="category")
```

```
In [58]: s.cat.categories
```

```
Out[58]: Index(['a', 'b', 'c'], dtype='object')
```

```
In [59]: s.cat.ordered
```

```
Out[59]: False
```

It's also possible to pass in the categories in a specific order:

```
In [60]: s = pd.Series(pd.Categorical(["a", "b", "c", "a"], categories=["c", "b", "a"]))
```

```
In [61]: s.cat.categories
```

```
Out[61]: Index(['c', 'b', 'a'], dtype='object')
```

```
In [62]: s.cat.ordered
```

```
Out[62]: False
```

Note: New categorical data are **not** automatically ordered. You must explicitly pass `ordered=True` to indicate an ordered `Categorical`.

Note: The result of `unique()` is not always the same as `Series.cat.categories`, because `Series.unique()` has a couple of guarantees, namely that it returns categories in the order of appearance, and it only includes values that are actually present.

```
In [63]: s = pd.Series(list("babc")).astype(CategoricalDtype(list("abcd")))
```

```
In [64]: s
```

```
Out[64]:
```

```
0    b
```

```
1    a
```

```
2    b
```

```
3    c
```

```
dtype: category
```

```
Categories (4, object): ['a', 'b', 'c', 'd']
```

```
# categories
```

```
In [65]: s.cat.categories
```

```
Out[65]: Index(['a', 'b', 'c', 'd'], dtype='object')
```

```
# uniques
```

```
In [66]: s.unique()
```

```
Out[66]:
```

```
['b', 'a', 'c']
```

```
Categories (4, object): ['a', 'b', 'c', 'd']
```

Renaming categories

Renaming categories is done by assigning new values to the `Series.cat.categories` property or by using the `rename_categories()` method:

```
In [67]: s = pd.Series(["a", "b", "c", "a"], dtype="category")
```

```
In [68]: s
```

```
Out[68]:
```

```
0    a  
1    b  
2    c  
3    a  
dtype: category  
Categories (3, object): ['a', 'b', 'c']
```

```
In [69]: s.cat.categories = ["Group %s" % g for g in s.cat.categories]
```

```
In [70]: s
```

```
Out[70]:
```

```
0    Group a  
1    Group b  
2    Group c  
3    Group a  
dtype: category  
Categories (3, object): ['Group a', 'Group b', 'Group c']
```

```
In [71]: s = s.cat.rename_categories([1, 2, 3])
```

```
In [72]: s
```

```
Out[72]:
```

```
0    1  
1    2  
2    3  
3    1  
dtype: category  
Categories (3, int64): [1, 2, 3]
```

```
# You can also pass a dict-like object to map the renaming
```

```
In [73]: s = s.cat.rename_categories({1: "x", 2: "y", 3: "z"})
```

```
In [74]: s
```

```
Out[74]:
```

```
0    x  
1    y  
2    z  
3    x  
dtype: category  
Categories (3, object): ['x', 'y', 'z']
```

Note: In contrast to R's factor, categorical data can have categories of other types than string.

Note: Be aware that assigning new categories is an inplace operation, while most other operations under `Series.cat` per default return a new Series of dtype category.

Categories must be unique or a `ValueError` is raised:

```
In [75]: try:
.....    s.cat.categories = [1, 1, 1]
..... except ValueError as e:
.....     print("ValueError:", str(e))
.....
ValueError: Categorical categories must be unique
```

Categories must also not be `NaN` or a `ValueError` is raised:

```
In [76]: try:
.....    s.cat.categories = [1, 2, np.nan]
..... except ValueError as e:
.....     print("ValueError:", str(e))
.....
ValueError: Categorical categories cannot be null
```

Appending new categories

Appending categories can be done by using the `add_categories()` method:

```
In [77]: s = s.cat.add_categories([4])
In [78]: s.cat.categories
Out[78]: Index(['x', 'y', 'z', 4], dtype='object')

In [79]: s
Out[79]:
0    x
1    y
2    z
3    x
dtype: category
Categories (4, object): ['x', 'y', 'z', 4]
```

Removing categories

Removing categories can be done by using the `remove_categories()` method. Values which are removed are replaced by `np.nan`:

```
In [80]: s = s.cat.remove_categories([4])
In [81]: s
Out[81]:
0    x
1    y
```

(continues on next page)

(continued from previous page)

```
2    z
3    x
dtype: category
Categories (3, object): ['x', 'y', 'z']
```

Removing unused categories

Removing unused categories can also be done:

```
In [82]: s = pd.Series(pd.Categorical(["a", "b", "a"], categories=["a", "b", "c", "d"]))
In [83]: s
Out[83]:
0    a
1    b
2    a
dtype: category
Categories (4, object): ['a', 'b', 'c', 'd']

In [84]: s.cat.remove_unused_categories()
Out[84]:
0    a
1    b
2    a
dtype: category
Categories (2, object): ['a', 'b']
```

Setting categories

If you want to do remove and add new categories in one step (which has some speed advantage), or simply set the categories to a predefined scale, use `set_categories()`.

```
In [85]: s = pd.Series(["one", "two", "four", "-"], dtype="category")
In [86]: s
Out[86]:
0    one
1    two
2    four
3    -
dtype: category
Categories (4, object): ['-', 'four', 'one', 'two']

In [87]: s = s.cat.set_categories(["one", "two", "three", "four"])

In [88]: s
Out[88]:
0    one
1    two
2    four
```

(continues on next page)

(continued from previous page)

```
3      NaN
dtype: category
Categories (4, object): ['one', 'two', 'three', 'four']
```

Note: Be aware that `Categorical.set_categories()` cannot know whether some category is omitted intentionally or because it is misspelled or (under Python3) due to a type difference (e.g., NumPy S1 dtype and Python strings). This can result in surprising behaviour!

2.12.5 Sorting and order

If categorical data is ordered (`s.cat.ordered == True`), then the order of the categories has a meaning and certain operations are possible. If the categorical is unordered, `.min()`/`.max()` will raise a `TypeError`.

```
In [89]: s = pd.Series(pd.Categorical(["a", "b", "c", "a"], ordered=False))

In [90]: s.sort_values(inplace=True)

In [91]: s = pd.Series(["a", "b", "c", "a"]).astype(CategoricalDtype(ordered=True))

In [92]: s.sort_values(inplace=True)

In [93]: s
Out[93]:
0    a
3    a
1    b
2    c
dtype: category
Categories (3, object): ['a' < 'b' < 'c']

In [94]: s.min(), s.max()
Out[94]: ('a', 'c')
```

You can set categorical data to be ordered by using `as_ordered()` or unordered by using `as_unordered()`. These will by default return a *new* object.

```
In [95]: s.cat.as_ordered()
Out[95]:
0    a
3    a
1    b
2    c
dtype: category
Categories (3, object): ['a' < 'b' < 'c']

In [96]: s.cat.as_unordered()
Out[96]:
0    a
3    a
```

(continues on next page)

(continued from previous page)

```
1    b
2    c
dtype: category
Categories (3, object): ['a', 'b', 'c']
```

Sorting will use the order defined by categories, not any lexical order present on the data type. This is even true for strings and numeric data:

```
In [97]: s = pd.Series([1, 2, 3, 1], dtype="category")

In [98]: s = s.cat.set_categories([2, 3, 1], ordered=True)

In [99]: s
Out[99]:
0    1
1    2
2    3
3    1
dtype: category
Categories (3, int64): [2 < 3 < 1]

In [100]: s.sort_values(inplace=True)

In [101]: s
Out[101]:
1    2
2    3
0    1
3    1
dtype: category
Categories (3, int64): [2 < 3 < 1]

In [102]: s.min(), s.max()
Out[102]: (2, 1)
```

Reordering

Reordering the categories is possible via the `Categorical.reorder_categories()` and the `Categorical.set_categories()` methods. For `Categorical.reorder_categories()`, all old categories must be included in the new categories and no new categories are allowed. This will necessarily make the sort order the same as the categories order.

```
In [103]: s = pd.Series([1, 2, 3, 1], dtype="category")

In [104]: s = s.cat.reorder_categories([2, 3, 1], ordered=True)

In [105]: s
Out[105]:
0    1
1    2
2    3
```

(continues on next page)

(continued from previous page)

```

3    1
dtype: category
Categories (3, int64): [2 < 3 < 1]

In [106]: s.sort_values(inplace=True)

In [107]: s
Out[107]:
1    2
2    3
0    1
3    1
dtype: category
Categories (3, int64): [2 < 3 < 1]

In [108]: s.min(), s.max()
Out[108]: (2, 1)

```

Note: Note the difference between assigning new categories and reordering the categories: the first renames categories and therefore the individual values in the `Series`, but if the first position was sorted last, the renamed value will still be sorted last. Reordering means that the way values are sorted is different afterwards, but not that individual values in the `Series` are changed.

Note: If the `Categorical` is not ordered, `Series.min()` and `Series.max()` will raise `TypeError`. Numeric operations like `+`, `-`, `*`, `/` and operations based on them (e.g. `Series.median()`, which would need to compute the mean between two values if the length of an array is even) do not work and raise a `TypeError`.

Multi column sorting

A categorical dtypes column will participate in a multi-column sort in a similar manner to other columns. The ordering of the categorical is determined by the `categories` of that column.

```

In [109]: dfs = pd.DataFrame(
...:     {
...:         "A": pd.Categorical(
...:             list("bbeebbaa"),
...:             categories=["e", "a", "b"],
...:             ordered=True,
...:         ),
...:         "B": [1, 2, 1, 2, 2, 1, 2, 1],
...:     }
...: )
...:

In [110]: dfs.sort_values(by=["A", "B"])
Out[110]:
   A  B
2  e  1

```

(continues on next page)

(continued from previous page)

```
3  e  2
7  a  1
6  a  2
0  b  1
5  b  1
1  b  2
4  b  2
```

Reordering the `categories` changes a future sort.

```
In [111]: df["A"] = df["A"].cat.reorder_categories(["a", "b", "e"])
```

```
In [112]: df.sort_values(by=["A", "B"])
```

```
Out[112]:
```

	A	B
7	a	1
6	a	2
0	b	1
5	b	1
1	b	2
4	b	2
2	e	1
3	e	2

2.12.6 Comparisons

Comparing categorical data with other objects is possible in three cases:

- Comparing equality (`==` and `!=`) to a list-like object (list, Series, array, ...) of the same length as the categorical data.
- All comparisons (`==`, `!=`, `>`, `>=`, `<`, and `<=`) of categorical data to another categorical Series, when `ordered=True` and the `categories` are the same.
- All comparisons of a categorical data to a scalar.

All other comparisons, especially “non-equality” comparisons of two categoricals with different categories or a categorical with any list-like object, will raise a `TypeError`.

Note: Any “non-equality” comparisons of categorical data with a Series, np.array, list or categorical data with different categories or ordering will raise a `TypeError` because custom categories ordering could be interpreted in two ways: one with taking into account the ordering and one without.

```
In [113]: cat = pd.Series([1, 2, 3]).astype(CategoricalDtype([3, 2, 1], ordered=True))
```

```
In [114]: cat_base = pd.Series([2, 2, 2]).astype(CategoricalDtype([3, 2, 1],  
    ↴ordered=True))
```

```
In [115]: cat_base2 = pd.Series([2, 2, 2]).astype(CategoricalDtype(ordered=True))
```

```
In [116]: cat
```

(continues on next page)

(continued from previous page)

Out[116]:

```
0    1
1    2
2    3
dtype: category
Categories (3, int64): [3 < 2 < 1]
```

In [117]: cat_base**Out[117]:**

```
0    2
1    2
2    2
dtype: category
Categories (3, int64): [3 < 2 < 1]
```

In [118]: cat_base2**Out[118]:**

```
0    2
1    2
2    2
dtype: category
Categories (1, int64): [2]
```

Comparing to a categorical with the same categories and ordering or to a scalar works:

In [119]: cat > cat_base**Out[119]:**

```
0    True
1   False
2   False
dtype: bool
```

In [120]: cat > 2**Out[120]:**

```
0    True
1   False
2   False
dtype: bool
```

Equality comparisons work with any list-like object of same length and scalars:

In [121]: cat == cat_base**Out[121]:**

```
0   False
1   True
2   False
dtype: bool
```

In [122]: cat == np.array([1, 2, 3])**Out[122]:**

```
0   True
1   True
```

(continues on next page)

(continued from previous page)

```
2    True  
dtype: bool
```

```
In [123]: cat == 2
```

```
Out[123]:
```

```
0    False  
1    True  
2    False  
dtype: bool
```

This doesn't work because the categories are not the same:

```
In [124]: try:  
.....:     cat > cat_base2  
.....: except TypeError as e:  
.....:     print("TypeError:", str(e))  
.....:
```

```
TypeError: Categoricals can only be compared if 'categories' are the same.
```

If you want to do a “non-equality” comparison of a categorical series with a list-like object which is not categorical data, you need to be explicit and convert the categorical data back to the original values:

```
In [125]: base = np.array([1, 2, 3])
```

```
In [126]: try:  
.....:     cat > base  
.....: except TypeError as e:  
.....:     print("TypeError:", str(e))  
.....:
```

```
TypeError: Cannot compare a Categorical for op __gt__ with type <class 'numpy.ndarray'>. If you want to compare values, use 'np.asarray(cat) <op> other'.
```

```
In [127]: np.asarray(cat) > base
```

```
Out[127]: array([False, False, False])
```

When you compare two unordered categoricals with the same categories, the order is not considered:

```
In [128]: c1 = pd.Categorical(["a", "b"], categories=["a", "b"], ordered=False)
```

```
In [129]: c2 = pd.Categorical(["a", "b"], categories=["b", "a"], ordered=False)
```

```
In [130]: c1 == c2
```

```
Out[130]: array([ True,  True])
```

2.12.7 Operations

Apart from `Series.min()`, `Series.max()` and `Series.mode()`, the following operations are possible with categorical data:

Series methods like `Series.value_counts()` will use all categories, even if some categories are not present in the data:

```
In [131]: s = pd.Series(pd.Categorical(["a", "b", "c", "c"], categories=["c", "a", "b",  
                           ↵"d"]))
In [132]: s.value_counts()
Out[132]:
c    2
a    1
b    1
d    0
dtype: int64
```

DataFrame methods like `DataFrame.sum()` also show “unused” categories.

```
In [133]: columns = pd.Categorical(  
.....:     ["One", "One", "Two"], categories=["One", "Two", "Three"], ordered=True  
.....:  
.....:  
In [134]: df = pd.DataFrame(  
.....:     data=[[1, 2, 3], [4, 5, 6]],  
.....:     columns=pd.MultiIndex.from_arrays([[["A", "B", "B"]], columns]),  
.....:  
.....:  
In [135]: df.groupby(axis=1, level=1).sum()
Out[135]:
      One   Two   Three
0      3     3      0
1      9     6      0
```

Groupby will also show “unused” categories:

```
In [136]: cats = pd.Categorical(  
.....:     ["a", "b", "b", "b", "c", "c", "c"], categories=["a", "b", "c", "d"]  
.....:  
.....:  
In [137]: df = pd.DataFrame({"cats": cats, "values": [1, 2, 2, 2, 3, 4, 5]})  
In [138]: df.groupby("cats").mean()
Out[138]:
      values
cats
a      1.0
b      2.0
c      4.0
```

(continues on next page)

(continued from previous page)

```
d      NaN

In [139]: cats2 = pd.Categorical(["a", "a", "b", "b"], categories=["a", "b", "c"])

In [140]: df2 = pd.DataFrame(
....:     {
....:         "cats": cats2,
....:         "B": ["c", "d", "c", "d"],
....:         "values": [1, 2, 3, 4],
....:     }
....: )
....:

In [141]: df2.groupby(["cats", "B"]).mean()
Out[141]:
      values
cats B
a    c    1.0
      d    2.0
b    c    3.0
      d    4.0
c    c    NaN
      d    NaN
```

Pivot tables:

```
In [142]: raw_cat = pd.Categorical(["a", "a", "b", "b"], categories=["a", "b", "c"])

In [143]: df = pd.DataFrame({"A": raw_cat, "B": ["c", "d", "c", "d"], "values": [1, 2, 3,
↪ 4]})

In [144]: pd.pivot_table(df, values="values", index=["A", "B"])
Out[144]:
      values
A B
a c    1
      d    2
b c    3
      d    4
```

2.12.8 Data munging

The optimized pandas data access methods `.loc`, `.iloc`, `.at`, and `.iat`, work as normal. The only difference is the return type (for getting) and that only values already in `categories` can be assigned.

Getting

If the slicing operation returns either a `DataFrame` or a column of type `Series`, the category dtype is preserved.

```
In [145]: idx = pd.Index(["h", "i", "j", "k", "l", "m", "n"])

In [146]: cats = pd.Series(["a", "b", "b", "b", "c", "c", "c"], dtype="category", index=idx)

In [147]: values = [1, 2, 2, 2, 3, 4, 5]

In [148]: df = pd.DataFrame({"cats": cats, "values": values}, index=idx)

In [149]: df.iloc[2:4, :]

Out[149]:
   cats  values
j      b      2
k      b      2

In [150]: df.iloc[2:4, :].dtypes

Out[150]:
cats      category
values     int64
dtype: object

In [151]: df.loc["h":"j", "cats"]
Out[151]:
h      a
i      b
j      b
Name: cats, dtype: category
Categories (3, object): ['a', 'b', 'c']

In [152]: df[df["cats"] == "b"]
Out[152]:
   cats  values
i      b      2
j      b      2
k      b      2
```

An example where the category type is not preserved is if you take one single row: the resulting `Series` is of dtype `object`:

```
# get the complete "h" row as a Series
In [153]: df.loc["h", :]

Out[153]:
cats      a
```

(continues on next page)

(continued from previous page)

```
values    1  
Name: h, dtype: object
```

Returning a single item from categorical data will also return the value, not a categorical of length “1”.

```
In [154]: df.iat[0, 0]  
Out[154]: 'a'  
  
In [155]: df["cats"].cat.categories = ["x", "y", "z"]  
  
In [156]: df.at["h", "cats"]  # returns a string  
Out[156]: 'x'
```

Note: This is in contrast to R’s `factor` function, where `factor(c(1,2,3))[1]` returns a single value `factor`.

To get a single value `Series` of type `category`, you pass in a list with a single value:

```
In [157]: df.loc[[ "h"], "cats"]  
Out[157]:  
h    x  
Name: cats, dtype: category  
Categories (3, object): ['x', 'y', 'z']
```

String and datetime accessors

The accessors `.dt` and `.str` will work if the `s.cat.categories` are of an appropriate type:

```
In [158]: str_s = pd.Series(list("aabb"))  
  
In [159]: str_cat = str_s.astype("category")  
  
In [160]: str_cat  
Out[160]:  
0    a  
1    a  
2    b  
3    b  
dtype: category  
Categories (2, object): ['a', 'b']  
  
In [161]: str_cat.str.contains("a")  
Out[161]:  
0    True  
1    True  
2   False  
3   False  
dtype: bool  
  
In [162]: date_s = pd.Series(pd.date_range("1/1/2015", periods=5))
```

(continues on next page)

(continued from previous page)

```
In [163]: date_cat = date_s.astype("category")

In [164]: date_cat
Out[164]:
0    2015-01-01
1    2015-01-02
2    2015-01-03
3    2015-01-04
4    2015-01-05
dtype: category
Categories (5, datetime64[ns]): [2015-01-01, 2015-01-02, 2015-01-03, 2015-01-04, 2015-01-05]

In [165]: date_cat.dt.day
Out[165]:
0    1
1    2
2    3
3    4
4    5
dtype: int64
```

Note: The returned Series (or DataFrame) is of the same type as if you used the `.str.<method>` / `.dt.<method>` on a Series of that type (and not of type `category`!).

That means, that the returned values from methods and properties on the accessors of a Series and the returned values from methods and properties on the accessors of this Series transformed to one of type `category` will be equal:

```
In [166]: ret_s = str_s.str.contains("a")

In [167]: ret_cat = str_cat.str.contains("a")

In [168]: ret_s.dtype == ret_cat.dtype
Out[168]: True

In [169]: ret_s == ret_cat
Out[169]:
0    True
1    True
2    True
3    True
dtype: bool
```

Note: The work is done on the `categories` and then a new Series is constructed. This has some performance implication if you have a Series of type string, where lots of elements are repeated (i.e. the number of unique elements in the Series is a lot smaller than the length of the Series). In this case it can be faster to convert the original Series to one of type `category` and use `.str.<method>` or `.dt.<property>` on that.

Setting

Setting values in a categorical column (or Series) works as long as the value is included in the categories:

```
In [170]: idx = pd.Index(["h", "i", "j", "k", "l", "m", "n"])

In [171]: cats = pd.Categorical(["a", "a", "a", "a", "a", "a", "a"], categories=["a", "b", "c"])
           ↓

In [172]: values = [1, 1, 1, 1, 1, 1, 1]

In [173]: df = pd.DataFrame({"cats": cats, "values": values}, index=idx)

In [174]: df.iloc[2:4, :] = [["b", 2], ["b", 2]]

In [175]: df
Out[175]:
   cats  values
h     a      1
i     a      1
j     b      2
k     b      2
l     a      1
m     a      1
n     a      1

In [176]: try:
.....:     df.iloc[2:4, :] = [["c", 3], ["c", 3]]
.....: except TypeError as e:
.....:     print("TypeError:", str(e))
.....:
```

TypeError: Cannot setitem on a Categorical with a new category, set the categories first

Setting values by assigning categorical data will also check that the categories match:

```
In [177]: df.loc["j":"k", "cats"] = pd.Categorical(["a", "a"], categories=["a", "b"])

In [178]: df
Out[178]:
   cats  values
h     a      1
i     a      1
j     a      2
k     a      2
l     a      1
m     a      1
n     a      1

In [179]: try:
.....:     df.loc["j":"k", "cats"] = pd.Categorical(["b", "b"], categories=["a", "b", "c"])
.....: except TypeError as e:
.....:     print("TypeError:", str(e))
.....:
```

(continues on next page)

(continued from previous page)

```
TypeError: Cannot set a Categorical with another, without identical categories
```

Assigning a Categorical to parts of a column of other types will use the values:

```
In [180]: df = pd.DataFrame({"a": [1, 1, 1, 1, 1], "b": ["a", "a", "a", "a", "a"]})

In [181]: df.loc[1:2, "a"] = pd.Categorical(["b", "b"], categories=["a", "b"])

In [182]: df.loc[2:3, "b"] = pd.Categorical(["b", "b"], categories=["a", "b"])

In [183]: df
Out[183]:
   a   b
0  1   a
1  b   a
2  b   b
3  1   b
4  1   a

In [184]: df.dtypes
Out[184]:
a    object
b    object
dtype: object
```

Merging / concatenation

By default, combining Series or DataFrames which contain the same categories results in category dtype, otherwise results will depend on the dtype of the underlying categories. Merges that result in non-categorical dtypes will likely have higher memory usage. Use .astype or union_categoricals to ensure category results.

```
In [185]: from pandas.api.types import union_categoricals

# same categories
In [186]: s1 = pd.Series(["a", "b"], dtype="category")

In [187]: s2 = pd.Series(["a", "b", "a"], dtype="category")

In [188]: pd.concat([s1, s2])
Out[188]:
0     a
1     b
0     a
1     b
2     a
dtype: category
Categories (2, object): ['a', 'b']

# different categories
In [189]: s3 = pd.Series(["b", "c"], dtype="category")
```

(continues on next page)

(continued from previous page)

```
In [190]: pd.concat([s1, s3])
Out[190]:
0    a
1    b
0    b
1    c
dtype: object

# Output dtype is inferred based on categories values
In [191]: int_cats = pd.Series([1, 2], dtype="category")

In [192]: float_cats = pd.Series([3.0, 4.0], dtype="category")

In [193]: pd.concat([int_cats, float_cats])
Out[193]:
0    1.0
1    2.0
0    3.0
1    4.0
dtype: float64

In [194]: pd.concat([s1, s3]).astype("category")
Out[194]:
0    a
1    b
0    b
1    c
dtype: category
Categories (3, object): ['a', 'b', 'c']

In [195]: union_categoricals([s1.array, s3.array])
Out[195]:
['a', 'b', 'b', 'c']
Categories (3, object): ['a', 'b', 'c']
```

The following table summarizes the results of merging Categoricals:

arg1	arg2	identical	result
category	category	True	category
category (object)	category (object)	False	object (dtype is inferred)
category (int)	category (float)	False	float (dtype is inferred)

See also the section on [merge dtypes](#) for notes about preserving merge dtypes and performance.

Unioning

If you want to combine categoricals that do not necessarily have the same categories, the `union_categoricals()` function will combine a list-like of categoricals. The new categories will be the union of the categories being combined.

```
In [196]: from pandas.api.types import union_categoricals
```

```
In [197]: a = pd.Categorical(["b", "c"])
```

```
In [198]: b = pd.Categorical(["a", "b"])
```

```
In [199]: union_categoricals([a, b])
```

```
Out[199]:
```

```
['b', 'c', 'a', 'b']
Categories (3, object): ['b', 'c', 'a']
```

By default, the resulting categories will be ordered as they appear in the data. If you want the categories to be lexicographically sorted, use `sort_categories=True` argument.

```
In [200]: union_categoricals([a, b], sort_categories=True)
```

```
Out[200]:
```

```
['b', 'c', 'a', 'b']
Categories (3, object): ['a', 'b', 'c']
```

`union_categoricals` also works with the “easy” case of combining two categoricals of the same categories and order information (e.g. what you could also append for).

```
In [201]: a = pd.Categorical(["a", "b"], ordered=True)
```

```
In [202]: b = pd.Categorical(["a", "b", "a"], ordered=True)
```

```
In [203]: union_categoricals([a, b])
```

```
Out[203]:
```

```
['a', 'b', 'a', 'b', 'a']
Categories (2, object): ['a' < 'b']
```

The below raises `TypeError` because the categories are ordered and not identical.

```
In [1]: a = pd.Categorical(["a", "b"], ordered=True)
```

```
In [2]: b = pd.Categorical(["a", "b", "c"], ordered=True)
```

```
In [3]: union_categoricals([a, b])
```

```
Out[3]:
```

```
TypeError: to union ordered Categoricals, all categories must be the same
```

Ordered categoricals with different categories or orderings can be combined by using the `ignore_ordered=True` argument.

```
In [204]: a = pd.Categorical(["a", "b", "c"], ordered=True)
```

```
In [205]: b = pd.Categorical(["c", "b", "a"], ordered=True)
```

```
In [206]: union_categoricals([a, b], ignore_order=True)
```

```
Out[206]:
```

```
['a', 'b', 'c', 'c', 'b', 'a']
Categories (3, object): ['a', 'b', 'c']
```

`union_categoricals()` also works with a `CategoricalIndex`, or `Series` containing categorical data, but note that the resulting array will always be a plain `Categorical`:

```
In [207]: a = pd.Series(["b", "c"], dtype="category")
In [208]: b = pd.Series(["a", "b"], dtype="category")
In [209]: union_categoricals([a, b])
Out[209]:
['b', 'c', 'a', 'b']
Categories (3, object): ['b', 'c', 'a']
```

Note: `union_categoricals` may recode the integer codes for categories when combining `categoricals`. This is likely what you want, but if you are relying on the exact numbering of the categories, be aware.

```
In [210]: c1 = pd.Categorical(["b", "c"])
In [211]: c2 = pd.Categorical(["a", "b"])
In [212]: c1
Out[212]:
['b', 'c']
Categories (2, object): ['b', 'c']

# "b" is coded to 0
In [213]: c1.codes
Out[213]: array([0, 1], dtype=int8)

In [214]: c2
Out[214]:
['a', 'b']
Categories (2, object): ['a', 'b']

# "b" is coded to 1
In [215]: c2.codes
Out[215]: array([0, 1], dtype=int8)

In [216]: c = union_categoricals([c1, c2])
In [217]: c
Out[217]:
['b', 'c', 'a', 'b']
Categories (3, object): ['b', 'c', 'a']

# "b" is coded to 0 throughout, same as c1, different from c2
In [218]: c.codes
Out[218]: array([0, 1, 2, 0], dtype=int8)
```

2.12.9 Getting data in/out

You can write data that contains category dtypes to a HDFStore. See [here](#) for an example and caveats.

It is also possible to write data to and reading data from *Stata* format files. See [here](#) for an example and caveats.

Writing to a CSV file will convert the data, effectively removing any information about the categorical (categories and ordering). So if you read back the CSV file you have to convert the relevant columns back to category and assign the right categories and categories ordering.

```
In [219]: import io

In [220]: s = pd.Series(pd.Categorical(["a", "b", "b", "a", "a", "d"]))

# rename the categories
In [221]: s.cat.categories = ["very good", "good", "bad"]

# reorder the categories and add missing categories
In [222]: s = s.cat.set_categories(["very bad", "bad", "medium", "good", "very good"])

In [223]: df = pd.DataFrame({"cats": s, "vals": [1, 2, 3, 4, 5, 6]})

In [224]: csv = io.StringIO()

In [225]: df.to_csv(csv)

In [226]: df2 = pd.read_csv(io.StringIO(csv.getvalue()))

In [227]: df2.dtypes
Out[227]:
Unnamed: 0      int64
cats            object
vals            int64
dtype: object

In [228]: df2["cats"]
Out[228]:
0    very good
1        good
2        good
3    very good
4    very good
5         bad
Name: cats, dtype: object

# Redo the category
In [229]: df2["cats"] = df2["cats"].astype("category")

In [230]: df2["cats"].cat.set_categories(
.....:     ["very bad", "bad", "medium", "good", "very good"], inplace=True
.....: )
.....:

In [231]: df2.dtypes
```

(continues on next page)

(continued from previous page)

Out[231]:

```
Unnamed: 0      int64
cats          category
vals          int64
dtype: object
```

In [232]: df2["cats"]**Out[232]:**

```
0    very good
1        good
2        good
3    very good
4    very good
5         bad
Name: cats, dtype: category
Categories (5, object): ['very bad', 'bad', 'medium', 'good', 'very good']
```

The same holds for writing to a SQL database with `to_sql`.

2.12.10 Missing data

pandas primarily uses the value `np.nan` to represent missing data. It is by default not included in computations. See the [Missing Data section](#).

Missing values should **not** be included in the Categorical's `categories`, only in the `values`. Instead, it is understood that `NaN` is different, and is always a possibility. When working with the Categorical's `codes`, missing values will always have a code of `-1`.

In [233]: s = pd.Series(["a", "b", np.nan, "a"], dtype="category")

only two categories

In [234]: s**Out[234]:**

```
0     a
1     b
2    NaN
3     a
dtype: category
Categories (2, object): ['a', 'b']
```

In [235]: s.cat.codes**Out[235]:**

```
0     0
1     1
2    -1
3     0
dtype: int8
```

Methods for working with missing data, e.g. `isna()`, `fillna()`, `dropna()`, all work normally:

In [236]: s = pd.Series(["a", "b", np.nan], dtype="category")

(continues on next page)

(continued from previous page)

```
In [237]: s
Out[237]:
0      a
1      b
2    NaN
dtype: category
Categories (2, object): ['a', 'b']

In [238]: pd.isna(s)
Out[238]:
0    False
1    False
2     True
dtype: bool

In [239]: s.fillna("a")
Out[239]:
0      a
1      b
2      a
dtype: category
Categories (2, object): ['a', 'b']
```

2.12.11 Differences to R's factor

The following differences to R's factor functions can be observed:

- R's `levels` are named `categories`.
- R's `levels` are always of type string, while `categories` in pandas can be of any `dtype`.
- It's not possible to specify labels at creation time. Use `s.cat.rename_categories(new_labels)` afterwards.
- In contrast to R's `factor` function, using categorical data as the sole input to create a new categorical series will *not* remove unused categories but create a new categorical series which is equal to the passed in one!
- R allows for missing values to be included in its `levels` (pandas' `categories`). pandas does not allow `NaN` categories, but missing values can still be in the `values`.

2.12.12 Gotchas

Memory usage

The memory usage of a `Categorical` is proportional to the number of categories plus the length of the data. In contrast, an `object` `dtype` is a constant times the length of the data.

```
In [240]: s = pd.Series(["foo", "bar"] * 1000)

# object dtype
In [241]: s nbytes
Out[241]: 16000
```

(continues on next page)

(continued from previous page)

```
# category dtype
In [242]: s.astype("category"). nbytes
Out[242]: 2016
```

Note: If the number of categories approaches the length of the data, the Categorical will use nearly the same or more memory than an equivalent object dtype representation.

```
In [243]: s = pd.Series(["foo%04d" % i for i in range(2000)])

# object dtype
In [244]: s nbytes
Out[244]: 16000

# category dtype
In [245]: s.astype("category"). nbytes
Out[245]: 20000
```

Categorical is not a numpy array

Currently, categorical data and the underlying Categorical is implemented as a Python object and not as a low-level NumPy array dtype. This leads to some problems.

NumPy itself doesn't know about the new dtype:

```
In [246]: try:
.....:     np.dtype("category")
.....: except TypeError as e:
.....:     print("TypeError:", str(e))
.....:

TypeError: data type 'category' not understood

In [247]: dtype = pd.Categorical(["a"]).dtype

In [248]: try:
.....:     np.dtype(dtype)
.....: except TypeError as e:
.....:     print("TypeError:", str(e))
.....:

TypeError: Cannot interpret 'CategoricalDtype(categories=['a'], ordered=False)' as a
data type
```

Dtype comparisons work:

```
In [249]: dtype == np.str_
Out[249]: False

In [250]: np.str_ == dtype
Out[250]: False
```

To check if a Series contains Categorical data, use `hasattr(s, 'cat')`:

```
In [251]: hasattr(pd.Series(["a"], dtype="category"), "cat")
Out[251]: True
```

```
In [252]: hasattr(pd.Series(["a"]), "cat")
Out[252]: False
```

Using NumPy functions on a Series of type category should not work as Categoricals are not numeric data (even in the case that .categories is numeric).

```
In [253]: s = pd.Series(pd.Categorical([1, 2, 3, 4]))
```

```
In [254]: try:
.....:     np.sum(s)
.....: except TypeError as e:
.....:     print("TypeError:", str(e))
.....:
```

```
TypeError: 'Categorical' with dtype category does not support reduction 'sum'
```

Note: If such a function works, please file a bug at <https://github.com/pandas-dev/pandas>!

dtype in apply

pandas currently does not preserve the dtype in apply functions: If you apply along rows you get a Series of object dtype (same as getting a row -> getting one element will return a basic type) and applying along columns will also convert to object. NaN values are unaffected. You can use fillna to handle missing values before applying a function.

```
In [255]: df = pd.DataFrame(
.....:     {
.....:         "a": [1, 2, 3, 4],
.....:         "b": ["a", "b", "c", "d"],
.....:         "cats": pd.Categorical([1, 2, 3, 2]),
.....:     }
.....: )
```

```
In [256]: df.apply(lambda row: type(row["cats"])), axis=1)
```

```
Out[256]:
0    <class 'int'>
1    <class 'int'>
2    <class 'int'>
3    <class 'int'>
dtype: object
```

```
In [257]: df.apply(lambda col: col.dtype, axis=0)
```

```
Out[257]:
a        int64
b        object
cats    category
dtype: object
```

Categorical index

CategoricalIndex is a type of index that is useful for supporting indexing with duplicates. This is a container around a Categorical and allows efficient indexing and storage of an index with a large number of duplicated elements. See the [advanced indexing docs](#) for a more detailed explanation.

Setting the index will create a CategoricalIndex:

```
In [258]: cats = pd.Categorical([1, 2, 3, 4], categories=[4, 2, 3, 1])

In [259]: strings = ["a", "b", "c", "d"]

In [260]: values = [4, 2, 3, 1]

In [261]: df = pd.DataFrame({"strings": strings, "values": values}, index=cats)

In [262]: df.index
Out[262]: CategoricalIndex([1, 2, 3, 4], categories=[4, 2, 3, 1], ordered=False, dtype='category')

# This now sorts by the categories order
In [263]: df.sort_index()
Out[263]:
   strings  values
4         d      1
2         b      2
3         c      3
1         a      4
```

Side effects

Constructing a Series from a Categorical will not copy the input Categorical. This means that changes to the Series will in most cases change the original Categorical:

```
In [264]: cat = pd.Categorical([1, 2, 3, 10], categories=[1, 2, 3, 4, 10])

In [265]: s = pd.Series(cat, name="cat")

In [266]: cat
Out[266]:
[1, 2, 3, 10]
Categories (5, int64): [1, 2, 3, 4, 10]

In [267]: s.iloc[0:2] = 10

In [268]: cat
Out[268]:
[10, 10, 3, 10]
Categories (5, int64): [1, 2, 3, 4, 10]

In [269]: df = pd.DataFrame(s)

In [270]: df["cat"].cat.categories = [1, 2, 3, 4, 5]
```

(continues on next page)

(continued from previous page)

```
In [271]: cat
Out[271]:
[10, 10, 3, 10]
Categories (5, int64): [1, 2, 3, 4, 10]
```

Use `copy=True` to prevent such a behaviour or simply don't reuse `Categoricals`:

```
In [272]: cat = pd.Categorical([1, 2, 3, 10], categories=[1, 2, 3, 4, 10])
In [273]: s = pd.Series(cat, name="cat", copy=True)
In [274]: cat
Out[274]:
[1, 2, 3, 10]
Categories (5, int64): [1, 2, 3, 4, 10]
In [275]: s.iloc[0:2] = 10
In [276]: cat
Out[276]:
[1, 2, 3, 10]
Categories (5, int64): [1, 2, 3, 4, 10]
```

Note: This also happens in some cases when you supply a NumPy array instead of a `Categorical`: using an int array (e.g. `np.array([1,2,3,4])`) will exhibit the same behavior, while using a string array (e.g. `np.array(["a","b","c","a"])`) will not.

2.13 Nullable integer data type

Note: `IntegerArray` is currently experimental. Its API or implementation may change without warning.

Changed in version 1.0.0: Now uses `pandas.NA` as the missing value rather than `numpy.nan`.

In [Working with missing data](#), we saw that pandas primarily uses `NaN` to represent missing data. Because `NaN` is a float, this forces an array of integers with any missing values to become floating point. In some cases, this may not matter much. But if your integer column is, say, an identifier, casting to float can be problematic. Some integers cannot even be represented as floating point numbers.

2.13.1 Construction

pandas can represent integer data with possibly missing values using `arrays.IntegerArray`. This is an *extension types* implemented within pandas.

```
In [1]: arr = pd.array([1, 2, None], dtype=pd.Int64Dtype())
In [2]: arr
Out[2]:
<IntegerArray>
[1, 2, <NA>]
Length: 3, dtype: Int64
```

Or the string alias "Int64" (note the capital "I", to differentiate from NumPy's 'int64' dtype:

```
In [3]: pd.array([1, 2, np.nan], dtype="Int64")
Out[3]:
<IntegerArray>
[1, 2, <NA>]
Length: 3, dtype: Int64
```

All NA-like values are replaced with pandas.NA.

```
In [4]: pd.array([1, 2, np.nan, None, pd.NA], dtype="Int64")
Out[4]:
<IntegerArray>
[1, 2, <NA>, <NA>, <NA>]
Length: 5, dtype: Int64
```

This array can be stored in a `DataFrame` or `Series` like any NumPy array.

```
In [5]: pd.Series(arr)
Out[5]:
0      1
1      2
2    <NA>
dtype: Int64
```

You can also pass the list-like object to the `Series` constructor with the dtype.

Warning: Currently `pandas.array()` and `pandas.Series()` use different rules for dtype inference. `pandas.array()` will infer a nullable-integer dtype

```
In [6]: pd.array([1, None])
Out[6]:
<IntegerArray>
[1, <NA>]
Length: 2, dtype: Int64

In [7]: pd.array([1, 2])
Out[7]:
<IntegerArray>
[1, 2]
Length: 2, dtype: Int64
```

For backwards-compatibility, `Series` infers these as either integer or float dtype

```
In [8]: pd.Series([1, None])
```

```
Out[8]:
```

```
0    1.0
1    NaN
dtype: float64
```

```
In [9]: pd.Series([1, 2])
```

```
Out[9]:
```

```
0    1
1    2
dtype: int64
```

We recommend explicitly providing the dtype to avoid confusion.

```
In [10]: pd.array([1, None], dtype="Int64")
```

```
Out[10]:
```

```
<IntegerArray>
[1, <NA>]
Length: 2, dtype: Int64
```

```
In [11]: pd.Series([1, None], dtype="Int64")
```

```
Out[11]:
```

```
0    1
1    <NA>
dtype: Int64
```

In the future, we may provide an option for `Series` to infer a nullable-integer dtype.

2.13.2 Operations

Operations involving an integer array will behave similar to NumPy arrays. Missing values will be propagated, and the data will be coerced to another dtype if needed.

```
In [12]: s = pd.Series([1, 2, None], dtype="Int64")
```

```
# arithmetic
```

```
In [13]: s + 1
```

```
Out[13]:
```

```
0    2
1    3
2    <NA>
dtype: Int64
```

```
# comparison
```

```
In [14]: s == 1
```

```
Out[14]:
```

```
0    True
1   False
2    <NA>
dtype: boolean
```

(continues on next page)

(continued from previous page)

```
# indexing
In [15]: s.iloc[1:3]
Out[15]:
1      2
2    <NA>
dtype: Int64

# operate with other dtypes
In [16]: s + s.iloc[1:3].astype("Int8")
Out[16]:
0    <NA>
1      4
2    <NA>
dtype: Int64

# coerce when needed
In [17]: s + 0.01
Out[17]:
0    1.01
1    2.01
2    <NA>
dtype: Float64
```

These dtypes can operate as part of DataFrame.

```
In [18]: df = pd.DataFrame({"A": s, "B": [1, 1, 3], "C": list("aab")})

In [19]: df
Out[19]:
   A  B  C
0  1  1  a
1  2  1  a
2  <NA>  3  b

In [20]: df.dtypes
Out[20]:
A    Int64
B    int64
C    object
dtype: object
```

These dtypes can be merged & reshaped & casted.

```
In [21]: pd.concat([df[["A"]], df[["B", "C"]]], axis=1).dtypes
Out[21]:
A    Int64
B    int64
C    object
dtype: object

In [22]: df["A"].astype(float)
Out[22]:
```

(continues on next page)

(continued from previous page)

```
0    1.0
1    2.0
2    NaN
Name: A, dtype: float64
```

Reduction and groupby operations such as ‘sum’ work as well.

```
In [23]: df.sum()
Out[23]:
A      3
B      5
C    aab
dtype: object

In [24]: df.groupby("B").A.sum()
Out[24]:
B
1      3
3      0
Name: A, dtype: Int64
```

2.13.3 Scalar NA Value

`arrays.IntegerArray` uses `pandas.NA` as its scalar missing value. Slicing a single element that’s missing will return `pandas.NA`

```
In [25]: a = pd.array([1, None], dtype="Int64")
In [26]: a[1]
Out[26]: <NA>
```

2.14 Nullable Boolean data type

Note: `BooleanArray` is currently experimental. Its API or implementation may change without warning.

New in version 1.0.0.

2.14.1 Indexing with NA values

pandas allows indexing with NA values in a boolean array, which are treated as `False`.

Changed in version 1.0.2.

```
In [1]: s = pd.Series([1, 2, 3])
In [2]: mask = pd.array([True, False, pd.NA], dtype="boolean")
```

(continues on next page)

(continued from previous page)

In [3]: s[mask]**Out[3]:**

```
0    1
dtype: int64
```

If you would prefer to keep the NA values you can manually fill them with `fillna(True)`.

In [4]: s[mask.fillna(True)]**Out[4]:**

```
0    1
2    3
dtype: int64
```

2.14.2 Kleene logical operations

`arrays.BooleanArray` implements Kleene Logic (sometimes called three-value logic) for logical operations like & (and), | (or) and ^ (exclusive-or).

This table demonstrates the results for every combination. These operations are symmetrical, so flipping the left- and right-hand side makes no difference in the result.

Expression	Result
True & True	True
True & False	False
True & NA	NA
False & False	False
False & NA	False
NA & NA	NA
True True	True
True False	True
True NA	True
False False	False
False NA	NA
NA NA	NA
True ^ True	False
True ^ False	True
True ^ NA	NA
False ^ False	False
False ^ NA	NA
NA ^ NA	NA

When an NA is present in an operation, the output value is NA only if the result cannot be determined solely based on the other input. For example, `True | NA` is True, because both `True | True` and `True | False` are True. In that case, we don't actually need to consider the value of the NA.

On the other hand, `True & NA` is NA. The result depends on whether the NA really is True or False, since `True & True` is True, but `True & False` is False, so we can't determine the output.

This differs from how `np.nan` behaves in logical operations. pandas treated `np.nan` is *always false in the output*.

In or

```
In [5]: pd.Series([True, False, np.nan], dtype="object") | True
```

```
Out[5]:
```

```
0    True
1    True
2   False
dtype: bool
```

```
In [6]: pd.Series([True, False, np.nan], dtype="boolean") | True
```

```
Out[6]:
```

```
0    True
1    True
2    True
dtype: boolean
```

In and

```
In [7]: pd.Series([True, False, np.nan], dtype="object") & True
```

```
Out[7]:
```

```
0    True
1   False
2   False
dtype: bool
```

```
In [8]: pd.Series([True, False, np.nan], dtype="boolean") & True
```

```
Out[8]:
```

```
0    True
1   False
2    <NA>
dtype: boolean
```

{{ header }}

2.15 Chart Visualization

This section demonstrates visualization through charting. For information on visualization of tabular data please see the section on [Table Visualization](#).

We use the standard convention for referencing the matplotlib API:

```
In [1]: import matplotlib.pyplot as plt
```

```
In [2]: plt.close("all")
```

We provide the basics in pandas to easily create decent looking plots. See the ecosystem section for visualization libraries that go beyond the basics documented here.

Note: All calls to `np.random` are seeded with 123456.

2.15.1 Basic plotting: plot

We will demonstrate the basics, see the [cookbook](#) for some advanced strategies.

The `plot` method on Series and DataFrame is just a simple wrapper around `plt.plot()`:

```
In [3]: ts = pd.Series(np.random.randn(1000), index=pd.date_range("1/1/2000", periods=1000))

In [4]: ts = ts.cumsum()

In [5]: ts.plot();
```

If the index consists of dates, it calls `gcf().autofmt_xdate()` to try to format the x-axis nicely as per above.

On DataFrame, `plot()` is a convenience to plot all of the columns with labels:

```
In [6]: df = pd.DataFrame(np.random.randn(1000, 4), index=ts.index, columns=list("ABCD"))

In [7]: df = df.cumsum()

In [8]: plt.figure();

In [9]: df.plot();
```

You can plot one column versus another using the `x` and `y` keywords in `plot()`:

```
In [10]: df3 = pd.DataFrame(np.random.randn(1000, 2), columns=["B", "C"]).cumsum()  
In [11]: df3["A"] = pd.Series(list(range(len(df))))  
In [12]: df3.plot(x="A", y="B");
```

Note: For more formatting and styling options, see [formatting](#) below.

2.15.2 Other plots

Plotting methods allow for a handful of plot styles other than the default line plot. These methods can be provided as the `kind` keyword argument to `plot()`, and include:

- '`bar`' or '`barh`' for bar plots
- '`hist`' for histogram
- '`box`' for boxplot
- '`kde`' or '`density`' for density plots
- '`area`' for area plots
- '`scatter`' for scatter plots
- '`hexbin`' for hexagonal bin plots
- '`pie`' for pie plots

For example, a bar plot can be created the following way:

```
In [13]: plt.figure();
```

```
In [14]: df.iloc[5].plot(kind="bar");
```

You can also create these other plots using the methods `DataFrame.plot.<kind>` instead of providing the `kind` keyword argument. This makes it easier to discover plot methods and the specific arguments they use:

```
In [15]: df = pd.DataFrame()
```

```
In [16]: df.plot.<TAB> # noqa: E225, E999
df.plot.area      df.plot.barsh     df.plot.density  df.plot.hist      df.plot.line      df.
    ↪plot.scatter
df.plot.bar       df.plot.box      df.plot.hexbin   df.plot.kde      df.plot.pie
```

In addition to these `kind`s, there are the `DataFrame.hist()`, and `DataFrame.boxplot()` methods, which use a separate interface.

Finally, there are several *plotting functions* in `pandas.plotting` that take a `Series` or `DataFrame` as an argument. These include:

- *Scatter Matrix*
- *Andrews Curves*
- *Parallel Coordinates*

- [Lag Plot](#)
- [Autocorrelation Plot](#)
- [Bootstrap Plot](#)
- [RadViz](#)

Plots may also be adorned with [errorbars](#) or [tables](#).

Bar plots

For labeled, non-time series data, you may wish to produce a bar plot:

```
In [17]: plt.figure();  
  
In [18]: df.iloc[5].plot.bar();  
  
In [19]: plt.axhline(0, color="k");
```

Calling a DataFrame's `plot.bar()` method produces a multiple bar plot:

```
In [20]: df2 = pd.DataFrame(np.random.rand(10, 4), columns=["a", "b", "c", "d"]);  
  
In [21]: df2.plot.bar();
```

To produce a stacked bar plot, pass `stacked=True`:

```
In [22]: df2.plot.bar(stacked=True);
```

To get horizontal bar plots, use the `barh` method:

```
In [23]: df2.plot.barh(stacked=True);
```

Histograms

Histograms can be drawn by using the `DataFrame.plot.hist()` and `Series.plot.hist()` methods.

```
In [24]: df4 = pd.DataFrame(
.....    {
.....        "a": np.random.randn(1000) + 1,
.....        "b": np.random.randn(1000),
.....        "c": np.random.randn(1000) - 1,
.....    },
.....    columns=["a", "b", "c"],
.....)
```

```
In [25]: plt.figure();
```

```
In [26]: df4.plot.hist(alpha=0.5);
```

A histogram can be stacked using `stacked=True`. Bin size can be changed using the `bins` keyword.

In [27]: `plt.figure()`

In [28]: `df4.plot.hist(stacked=True, bins=20)`

You can pass other keywords supported by matplotlib hist. For example, horizontal and cumulative histograms can be drawn by `orientation='horizontal'` and `cumulative=True`.

```
In [29]: plt.figure();
```

```
In [30]: df4["a"].plot.hist(orientation="horizontal", cumulative=True);
```

See the `hist` method and the [matplotlib hist documentation](#) for more.

The existing interface `DataFrame.hist` to plot histogram still can be used.

```
In [31]: plt.figure();
```

```
In [32]: df[["A"]].diff().hist();
```

DataFrame.hist() plots the histograms of the columns on multiple subplots:

```
In [33]: plt.figure();
```

```
In [34]: df.diff().hist(color="k", alpha=0.5, bins=50);
```

The `by` keyword can be specified to plot grouped histograms:

```
In [35]: data = pd.Series(np.random.randn(1000))
```

```
In [36]: data.hist(by=np.random.randint(0, 4, 1000), figsize=(6, 4));
```

In addition, the `by` keyword can also be specified in `DataFrame.plot.hist()`.

Changed in version 1.4.0.

```
In [37]: data = pd.DataFrame(  
.....:     {  
.....:         "a": np.random.choice(["x", "y", "z"], 1000),  
.....:         "b": np.random.choice(["e", "f", "g"], 1000),  
.....:         "c": np.random.randn(1000),  
.....:         "d": np.random.randn(1000) - 1,  
.....:     },  
.....: )  
  
In [38]: data.plot.hist(by=["a", "b"], figsize=(10, 5));
```

Box plots

Boxplot can be drawn calling `Series.plot.box()` and `DataFrame.plot.box()`, or `DataFrame.boxplot()` to visualize the distribution of values within each column.

For instance, here is a boxplot representing five trials of 10 observations of a uniform random variable on [0,1).

```
In [39]: df = pd.DataFrame(np.random.rand(10, 5), columns=["A", "B", "C", "D", "E"])
```

```
In [40]: df.plot.box();
```

Boxplot can be colorized by passing `color` keyword. You can pass a `dict` whose keys are `boxes`, `whiskers`, `medians` and `caps`. If some keys are missing in the `dict`, default colors are used for the corresponding artists. Also, boxplot has `sym` keyword to specify fliers style.

When you pass other type of arguments via `color` keyword, it will be directly passed to matplotlib for all the `boxes`, `whiskers`, `medians` and `caps` colorization.

The colors are applied to every boxes to be drawn. If you want more complicated colorization, you can get each drawn artists by passing `return_type`.

```
In [41]: color = {
    ....:     "boxes": "DarkGreen",
    ....:     "whiskers": "DarkOrange",
    ....:     "medians": "DarkBlue",
    ....:     "caps": "Gray",
    ....: }
```

```
In [42]: df.plot.box(color=color, sym="r+");
```

Also, you can pass other keywords supported by matplotlib boxplot. For example, horizontal and custom-positioned boxplot can be drawn by `vert=False` and `positions` keywords.

```
In [43]: df.plot.box(vert=False, positions=[1, 4, 5, 6, 8]);
```

See the `boxplot` method and the [matplotlib boxplot documentation](#) for more.

The existing interface `DataFrame.boxplot` still can be used.

```
In [44]: df = pd.DataFrame(np.random.rand(10, 5))
```

```
In [45]: plt.figure();
```

```
In [46]: bp = df.boxplot()
```

You can create a stratified boxplot using the `by` keyword argument to create groupings. For instance,

```
In [47]: df = pd.DataFrame(np.random.rand(10, 2), columns=["Col1", "Col2"])
```

```
In [48]: df["X"] = pd.Series(["A", "A", "A", "A", "A", "B", "B", "B", "B", "B"])
```

```
In [49]: plt.figure();
```

```
In [50]: bp = df.boxplot(by="X")
```

You can also pass a subset of columns to plot, as well as group by multiple columns:

```
In [51]: df = pd.DataFrame(np.random.rand(10, 3), columns=["Col1", "Col2", "Col3"])

In [52]: df["X"] = pd.Series(["A", "A", "A", "A", "A", "B", "B", "B", "B", "B"])

In [53]: df["Y"] = pd.Series(["A", "B", "A", "B", "A", "B", "A", "B", "A", "B"])

In [54]: plt.figure();

In [55]: bp = df.boxplot(column=["Col1", "Col2"], by=[ "X", "Y"])
```

You could also create groupings with `DataFrame.plot.box()`, for instance:

Changed in version 1.4.0.

```
In [56]: df = pd.DataFrame(np.random.rand(10, 3), columns=["Col1", "Col2", "Col3"])
```

```
In [57]: df["X"] = pd.Series(["A", "A", "A", "A", "A", "B", "B", "B", "B", "B"])
```

```
In [58]: plt.figure();
```

```
In [59]: bp = df.plot.box(column=['Col1', 'Col2'], by="X")
```

In boxplot, the return type can be controlled by the `return_type`, keyword. The valid choices are {"`axes`", "`dict`", "`both`", `None`}. Faceting, created by `DataFrame.boxplot` with the `by` keyword, will affect the output type as well:

<code>return_type</code>	Faceted	Output type
<code>None</code>	No	<code>axes</code>
<code>None</code>	Yes	2-D ndarray of axes
' <code>axes</code> '	No	<code>axes</code>
' <code>axes</code> '	Yes	Series of axes
' <code>dict</code> '	No	<code>dict</code> of artists
' <code>dict</code> '	Yes	Series of dicts of artists
' <code>both</code> '	No	namedtuple
' <code>both</code> '	Yes	Series of namedtuples

`Groupby.boxplot` always returns a Series of `return_type`.

```
In [60]: np.random.seed(1234)
```

```
In [61]: df_box = pd.DataFrame(np.random.randn(50, 2))
```

```
In [62]: df_box["g"] = np.random.choice(["A", "B"], size=50)
```

```
In [63]: df_box.loc[df_box["g"] == "B", 1] += 3
```

(continues on next page)

(continued from previous page)

```
In [64]: bp = df_box.boxplot(by="g")
```

The subplots above are split by the numeric columns first, then the value of the g column. Below the subplots are first split by the value of g, then by the numeric columns.

```
In [65]: bp = df_box.groupby("g").boxplot()
```

Area plot

You can create area plots with `Series.plot.area()` and `DataFrame.plot.area()`. Area plots are stacked by default. To produce stacked area plot, each column must be either all positive or all negative values.

When input data contains `NaN`, it will be automatically filled by 0. If you want to drop or fill by different values, use `dataframe.dropna()` or `dataframe.fillna()` before calling plot.

```
In [66]: df = pd.DataFrame(np.random.rand(10, 4), columns=["a", "b", "c", "d"])
```

```
In [67]: df.plot.area();
```

To produce an unstacked plot, pass `stacked=False`. Alpha value is set to 0.5 unless otherwise specified:

```
In [68]: df.plot.area(stacked=False);
```

Scatter plot

Scatter plot can be drawn by using the `DataFrame.plot.scatter()` method. Scatter plot requires numeric columns for the x and y axes. These can be specified by the `x` and `y` keywords.

```
In [69]: df = pd.DataFrame(np.random.rand(50, 4), columns=["a", "b", "c", "d"])
```

```
In [70]: df["species"] = pd.Categorical(
.....    ["setosa"] * 20 + ["versicolor"] * 20 + ["virginica"] * 10
.....)
.....
```

```
In [71]: df.plot.scatter(x="a", y="b");
```

To plot multiple column groups in a single axes, repeat `plot` method specifying target `ax`. It is recommended to specify `color` and `label` keywords to distinguish each groups.

```
In [72]: ax = df.plot.scatter(x="a", y="b", color="DarkBlue", label="Group 1")
```

```
In [73]: df.plot.scatter(x="c", y="d", color="DarkGreen", label="Group 2", ax=ax);
```

The keyword `c` may be given as the name of a column to provide colors for each point:

```
In [74]: df.plot.scatter(x="a", y="b", c="c", s=50);
```

If a categorical column is passed to `c`, then a discrete colorbar will be produced:

New in version 1.3.0.

```
In [75]: df.plot.scatter(x="a", y="b", c="species", cmap="viridis", s=50);
```

You can pass other keywords supported by matplotlib `scatter`. The example below shows a bubble chart using a column of the DataFrame as the bubble size.

```
In [76]: df.plot.scatter(x="a", y="b", s=df["c"] * 200);
```

See the `scatter` method and the [matplotlib scatter documentation](#) for more.

Hexagonal bin plot

You can create hexagonal bin plots with `DataFrame.plot.hexbin()`. Hexbin plots can be a useful alternative to scatter plots if your data are too dense to plot each point individually.

```
In [77]: df = pd.DataFrame(np.random.randn(1000, 2), columns=["a", "b"])
```

```
In [78]: df["b"] = df["b"] + np.arange(1000)
```

```
In [79]: df.plot.hexbin(x="a", y="b", gridsize=25);
```

A useful keyword argument is `gridsize`; it controls the number of hexagons in the x-direction, and defaults to 100. A larger `gridsize` means more, smaller bins.

By default, a histogram of the counts around each (`x`, `y`) point is computed. You can specify alternative aggregations by passing values to the `C` and `reduce_C_function` arguments. `C` specifies the value at each (`x`, `y`) point and `reduce_C_function` is a function of one argument that reduces all the values in a bin to a single number (e.g. `mean`, `max`, `sum`, `std`). In this example the positions are given by columns `a` and `b`, while the value is given by column `z`. The bins are aggregated with NumPy's `max` function.

```
In [80]: df = pd.DataFrame(np.random.randn(1000, 2), columns=["a", "b"])

In [81]: df["b"] = df["b"] + np.arange(1000)

In [82]: df["z"] = np.random.uniform(0, 3, 1000)

In [83]: df.plot.hexbin(x="a", y="b", C="z", reduce_C_function=np.max, gridsize=25);
```

See the `hexbin` method and the [matplotlib hexbin documentation](#) for more.

Pie plot

You can create a pie plot with `DataFrame.plot.pie()` or `Series.plot.pie()`. If your data includes any `NaN`, they will be automatically filled with 0. A `ValueError` will be raised if there are any negative values in your data.

```
In [84]: series = pd.Series(3 * np.random.rand(4), index=["a", "b", "c", "d"], name="series")
```

```
In [85]: series.plot.pie(figsize=(6, 6));
```

For pie plots it's best to use square figures, i.e. a figure aspect ratio 1. You can create the figure with equal width and height, or force the aspect ratio to be equal after plotting by calling `ax.set_aspect('equal')` on the returned axes object.

Note that pie plot with `DataFrame` requires that you either specify a target column by the `y` argument or `subplots=True`. When `y` is specified, pie plot of selected column will be drawn. If `subplots=True` is specified, pie plots for each column are drawn as subplots. A legend will be drawn in each pie plots by default; specify `legend=False` to hide it.

```
In [86]: df = pd.DataFrame(  
.....:     3 * np.random.rand(4, 2), index=["a", "b", "c", "d"], columns=["x", "y"]  
.....:  
.....:
```

```
In [87]: df.plot.pie(subplots=True, figsize=(8, 4));
```

You can use the `labels` and `colors` keywords to specify the labels and colors of each wedge.

Warning: Most pandas plots use the `label` and `color` arguments (note the lack of “s” on those). To be consistent with `matplotlib.pyplot.pie()` you must use `labels` and `colors`.

If you want to hide wedge labels, specify `labels=None`. If `fontsize` is specified, the value will be applied to wedge labels. Also, other keywords supported by `matplotlib.pyplot.pie()` can be used.

```
In [88]: series.plot.pie(  
.....:     labels=["AA", "BB", "CC", "DD"],  
.....:     colors=["r", "g", "b", "c"],  
.....:     autopct="%2f",  
.....:     fontsize=20,  
.....:     figsize=(6, 6),  
.....: );  
.....:
```

If you pass values whose sum total is less than 1.0, matplotlib draws a semicircle.

```
In [89]: series = pd.Series([0.1] * 4, index=["a", "b", "c", "d"], name="series2")  
In [90]: series.plot.pie(figsize=(6, 6));
```

See the [matplotlib pie documentation](#) for more.

2.15.3 Plotting with missing data

pandas tries to be pragmatic about plotting DataFrames or Series that contain missing data. Missing values are dropped, left out, or filled depending on the plot type.

Plot Type	NaN Handling
Line	Leave gaps at NaNs
Line (stacked)	Fill 0's
Bar	Fill 0's
Scatter	Drop NaNs
Histogram	Drop NaNs (column-wise)
Box	Drop NaNs (column-wise)
Area	Fill 0's
KDE	Drop NaNs (column-wise)
Hexbin	Drop NaNs
Pie	Fill 0's

If any of these defaults are not what you want, or if you want to be explicit about how missing values are handled, consider using `fillna()` or `dropna()` before plotting.

2.15.4 Plotting tools

These functions can be imported from `pandas.plotting` and take a `Series` or `DataFrame` as an argument.

Scatter matrix plot

You can create a scatter plot matrix using the `scatter_matrix` method in `pandas.plotting`:

```
In [91]: from pandas.plotting import scatter_matrix  
  
In [92]: df = pd.DataFrame(np.random.randn(1000, 4), columns=["a", "b", "c", "d"])  
  
In [93]: scatter_matrix(df, alpha=0.2, figsize=(6, 6), diagonal="kde");
```

Density plot

You can create density plots using the `Series.plot.kde()` and `DataFrame.plot.kde()` methods.

```
In [94]: ser = pd.Series(np.random.randn(1000))
```

```
In [95]: ser.plot.kde();
```

Andrews curves 安德鲁斯曲线

Andrews curves allow one to plot multivariate data as a large number of curves that are created using the attributes of samples as coefficients for Fourier series, see the [Wikipedia entry](#) for more information. By coloring these curves differently for each class it is possible to visualize data clustering. Curves belonging to samples of the same class will usually be closer together and form larger structures.

Note: The “Iris” dataset is available [here](#).

```
In [96]: from pandas.plotting import andrews_curves
```

```
In [97]: data = pd.read_csv("data/iris.data")
```

```
In [98]: plt.figure();
```

```
In [99]: andrews_curves(data, "Name");
```

Andrews 曲线允许将多变量数据绘制为使用属性创建的大量曲线。有关傅里叶级数的系数示例，请参阅维基百科条目以了解更多信息。通过给这些曲线上色对于每一个类，可以通过不同的方式可视化数据集群。属于同一类别样本的曲线将通常靠得更近，形成更大的结构。

安德鲁斯曲线，函数形式：

$$f(t) = x_1/\sqrt{2} + x_2 \sin(t) + x_3 \cos(t) + x_4 \sin(2t) + x_5 \cos(2t) + \dots$$

其中 x 系数对应于每个维度的值，并且 t 在 $-\pi$ 和 π 之间呈线性间隔。然后每一行框架对应于一条曲线。

Parallel coordinates

Parallel coordinates is a plotting technique for plotting multivariate data, see the [Wikipedia entry](#) for an introduction. Parallel coordinates allows one to see clusters in data and to estimate other statistics visually. Using parallel coordinates points are represented as connected line segments. Each vertical line represents one attribute. One set of connected line segments represents one data point. Points that tend to cluster will appear closer together.

```
In [100]: from pandas.plotting import parallel_coordinates  
  
In [101]: data = pd.read_csv("data/iris.data")  
  
In [102]: plt.figure();  
  
In [103]: parallel_coordinates(data, "Name");
```

Lag plot

Lag plots are used to check if a data set or time series is random. Random data should not exhibit any structure in the lag plot. Non-random structure implies that the underlying data are not random. The `lag` argument may be passed, and when `lag=1` the plot is essentially `data[:-1]` vs. `data[1:]`.

```
In [104]: from pandas.plotting import lag_plot
In [105]: plt.figure();
In [106]: spacing = np.linspace(-99 * np.pi, 99 * np.pi, num=1000)
In [107]: data = pd.Series(0.1 * np.random.rand(1000) + 0.9 * np.sin(spacing))
In [108]: lag_plot(data);
```

滞后图用于检查数据集或时间序列是否随机。随机数据不应在滞后图。非随机结构意味着基础数据不是随机的。滞后论点可能会被通过，当`lag=1`时，曲线图本质上是数据`[: -1]`与数据`[1 :]`。

Autocorrelation plot

Autocorrelation plots are often used for checking randomness in time series. This is done by computing autocorrelations for data values at varying time lags. If time series is random, such autocorrelations should be near zero for any and all time-lag separations. If time series is non-random then one or more of the autocorrelations will be significantly non-zero. The horizontal lines displayed in the plot correspond to 95% and 99% confidence bands. The dashed line is 99% confidence band. See the [Wikipedia entry](#) for more about autocorrelation plots.

```
In [109]: from pandas.plotting import autocorrelation_plot
In [110]: plt.figure();
In [111]: spacing = np.linspace(-9 * np.pi, 9 * np.pi, num=1000)
In [112]: data = pd.Series(0.7 * np.random.rand(1000) + 0.3 * np.sin(spacing))
In [113]: autocorrelation_plot(data);
```

自相关图通常用于检查时间序列中的随机性。这是通过计算自相关来实现的
用于不同时间滞后的数据值。如果时间序列是随机的，那么对于任何一个时间序列，这种自相关都应该接近于零
所有时滞分离。如果时间序列是非随机的，那么一个或多个自相关将显著增加
非零。图中显示的水平线对应于95%和99%的置信区间。虚线是
99%置信区间。有关自相关图的更多信息，请参见维基百科条目。

Bootstrap plot

Bootstrap plots are used to visually assess the uncertainty of a statistic, such as mean, median, midrange, etc. A random subset of a specified size is selected from a data set, the statistic in question is computed for this subset and the process is repeated a specified number of times. Resulting plots and histograms are what constitutes the bootstrap plot.

```
In [114]: from pandas.plotting import bootstrap_plot
```

```
In [115]: data = pd.Series(np.random.rand(1000))
```

```
In [116]: bootstrap_plot(data, size=50, samples=500, color="grey");
```

Bootstrap又称自展法、自助法、自助法、靴带法，是统计学习中一种重采样(Resampling)技术，用来估计标准误差、置信区间和偏差。

Bootstrap是现代统计学较为流行的一种统计方法，在小样本时效果很好。机器学习中的Bagging, AdaBoost等方法其实都蕴含了Bootstrap的思想，在集成学习的范畴里 Bootstrap直接派生出了Bagging模型。

子样本之于样本，可以类比样本之于总体

举例

栗子：我要统计鱼塘里面的鱼的条数，怎么统计呢？假设鱼塘总共有鱼1000条，我是开了上帝视角的，但是你是不知道里面有多少。

步骤：

1. 承包鱼塘，不让别人捞鱼（规定总体分布不变）。
2. 自己捞鱼，捞100条，都打上标签（构造样本）
3. 把鱼放回鱼塘，休息一晚（使之混入整个鱼群，确保之后抽样随机）
4. 开始捞鱼，每次捞100条，数一下，自己昨天标记的鱼有多少条，占比多少（一次重采样取分布）。
5. 重复3, 4步骤n次。建立分布。

（原理是中心极限定理）

假设一下，第一次重新捕鱼100条，发现里面有标记的鱼12条，记下12%，放回去，再捕鱼100条，发现标记的为9条，记下9%，重复重复好多次之后，假设取置信区间95%，你会发现，每次捕鱼平均在10条左右有标记，所以，我们可以大致推测出鱼塘有1000条左右。其实是一个很简单的类似于一个比例问题。这也是因为提出者Efron给统计学顶级期刊投稿的时候被拒绝的理由——“太简单”。这也解释了，为什么在小样本的时候，bootstrap效果较好，你这样想，如果我想统计大海里有多少鱼，你标记100000条也没用啊，因为实际数量太过庞大，你取的样本相比于太渺小，最实际的就是，你下次再捕100000的时候，发现一条都没有标记，就尴尬了。。。

RadViz

RadViz is a way of visualizing multi-variate data. It is Basically you set up a bunch of points in a plane. In our represents a single attribute. You then pretend that each spring, the stiffness of which is proportional to the numeric The point in the plane, where our sample settles to (where a dot representing our sample will be drawn. Depen differently. See the R package [RadViz](#) for more information.

Note: The “Iris” dataset is available [here](#).

```
In [117]: from pandas.plotting import radviz
In [118]: data = pd.read_csv("data/iris.data")
In [119]: plt.figure();
In [120]: radviz(data, "Name");
```

Radviz可视化原理是将一系列多维空间的点通过非线性方法映射到二维空间的可视化技术，是基于圆形平行坐标系的设计思想而提出的多维可视化方法。圆形的m条半径表示m维空间，使用坐标系中的一点代表多维信息对象，其实现原理参照物理学中物体受力平衡定理。

首先将一个圆等分成 m 份，等分点的个数由数据维度决定，记各等分点为 $\{R_1, R_2, \dots, R_n\}$ ，每个等分点上固定一个弹簧，各个弹簧的弹性系数不同，弹簧 i,j 的弹性系数是 $A_{ij}A_{ji}$ ，也就是第 j 维的值，所有 m 个弹簧的另一端都固定在一个小圆上，如果这个小圆最终达到一个平衡位置 $B_i = \{X_i, Y_i\}$ ， $T B_i = \{X_i, Y_i\}^T$ ，则弹力平衡点 $\{X_i, Y_i\}$ 就是 m 维空间点 $\{A_{i1}, A_{i2}, \dots, A_{im}\}$ 在二维空间的投影点。

如下图所示：

2.15.5 Plot formatting

Setting the plot style

From version 1.5 and up, matplotlib offers a range of pre-configured plotting styles. Setting the style can be used to easily give plots the general look that you want. Setting the style is as easy as calling `matplotlib.style.use(my_plot_style)` before creating your plot. For example you could write `matplotlib.style.use('ggplot')` for ggplot-style plots.

You can see the various available style names at `matplotlib.style.available` and it's very easy to try them out.

General plot style arguments

Most plotting methods have a set of keyword arguments that control the layout and formatting of the returned plot:

```
In [121]: plt.figure();
In [122]: ts.plot(style="k--", label="Series");
```

For each kind of plot (e.g. `line`, `bar`, `scatter`) any additional arguments keywords are passed along to the corresponding matplotlib function (`ax.plot()`, `ax.bar()`, `ax.scatter()`). These can be used to control additional styling, beyond what pandas provides.

Controlling the legend

You may set the `legend` argument to `False` to hide the legend, which is shown by default.

```
In [123]: df = pd.DataFrame(np.random.randn(1000, 4), index=ts.index, columns=list("ABCD"))
          ↵
In [124]: df = df.cumsum()
          ↵
In [125]: df.plot(legend=False);
```

Controlling the labels

New in version 1.1.0.

You may set the `xlabel` and `ylabel` arguments to give the plot custom labels for x and y axis. By default, pandas will pick up index name as `xlabel`, while leaving it empty for `ylabel`.

```
In [126]: df.plot();
```

```
In [127]: df.plot(xlabel="new x", ylabel="new y");
```

Scales

You may pass `logy` to get a log-scale Y axis.

```
In [128]: ts = pd.Series(np.random.randn(1000), index=pd.date_range("1/1/2000", periods=1000))
```

```
In [129]: ts = np.exp(ts.cumsum())
```

```
In [130]: ts.plot(logy=True);
```

See also the `logx` and `loglog` keyword arguments.

Plotting on a secondary y-axis

To plot data on a secondary y-axis, use the `secondary_y` keyword:

```
In [131]: df["A"].plot();
```

```
In [132]: df["B"].plot(secondary_y=True, style="g");
```

To plot some columns in a DataFrame, give the column names to the `secondary_y` keyword:

```
In [133]: plt.figure();

In [134]: ax = df.plot(secondary_y=["A", "B"])

In [135]: ax.set_ylabel("CD scale");

In [136]: ax.right_ax.set_ylabel("AB scale");
```

Note that the columns plotted on the secondary y-axis is automatically marked with “(right)” in the legend. To turn off the automatic marking, use the `mark_right=False` keyword:

```
In [137]: plt.figure();
```

```
In [138]: df.plot(secondary_y=["A", "B"], mark_right=False);
```

Custom formatters for timeseries plots

Changed in version 1.0.0.

pandas provides custom formatters for timeseries plots. These change the formatting of the axis labels for dates and times. By default, the custom formatters are applied only to plots created by pandas with `DataFrame.plot()` or `Series.plot()`. To have them apply to all plots, including those made by matplotlib, set the option `pd.options.plotting.matplotlib.register_converters = True` or use `pandas.plotting.register_matplotlib_converters()`.

Suppressing tick resolution adjustment

pandas includes automatic tick resolution adjustment for regular frequency time-series data. For limited cases where pandas cannot infer the frequency information (e.g., in an externally created `twinx`), you can choose to suppress this behavior for alignment purposes.

Here is the default behavior, notice how the x-axis tick labeling is performed:

```
In [139]: plt.figure();
```

```
In [140]: df["A"].plot();
```

Using the `x_compat` parameter, you can suppress this behavior:

```
In [141]: plt.figure();
```

```
In [142]: df["A"].plot(x_compat=True);
```

If you have more than one plot that needs to be suppressed, the `use` method in `pandas.plotting.plot_params` can be used in a `with` statement:

```
In [143]: plt.figure();

In [144]: with pd.plotting.plot_params.use("x_compat", True):
.....:     df["A"].plot(color="r")
.....:     df["B"].plot(color="g")
.....:     df["C"].plot(color="b")
.....:
```

Automatic date tick adjustment

TimedeltaIndex now uses the native matplotlib tick locator methods, it is useful to call the automatic date tick adjustment from matplotlib for figures whose ticklabels overlap.

See the `autofmt_xdate` method and the [matplotlib](#) documentation for more.

Subplots

Each Series in a DataFrame can be plotted on a different axis with the `subplots` keyword:

```
In [145]: df.plot(subplots=True, figsize=(6, 6));
```

Using layout and targeting multiple axes

The layout of subplots can be specified by the `layout` keyword. It can accept `(rows, columns)`. The `layout` keyword can be used in `hist` and `boxplot` also. If the input is invalid, a `ValueError` will be raised.

The number of axes which can be contained by rows x columns specified by `layout` must be larger than the number of required subplots. If layout can contain more axes than required, blank axes are not drawn. Similar to a NumPy array's `reshape` method, you can use `-1` for one dimension to automatically calculate the number of rows or columns needed, given the other.

```
In [146]: df.plot(subplots=True, layout=(2, 3), figsize=(6, 6), sharex=False);
```

The above example is identical to using:

```
In [147]: df.plot(subplots=True, layout=(2, -1), figsize=(6, 6), sharex=False);
```

The required number of columns (3) is inferred from the number of series to plot and the given number of rows (2).

You can pass multiple axes created beforehand as list-like via `ax` keyword. This allows more complicated layouts. The passed axes must be the same number as the subplots being drawn.

When multiple axes are passed via the `ax` keyword, `layout`, `sharex` and `sharey` keywords don't affect to the output. You should explicitly pass `sharex=False` and `sharey=False`, otherwise you will see a warning.

```
In [148]: fig, axes = plt.subplots(4, 4, figsize=(9, 9))

In [149]: plt.subplots_adjust(wspace=0.5, hspace=0.5)

In [150]: target1 = [axes[0][0], axes[1][1], axes[2][2], axes[3][3]]

In [151]: target2 = [axes[3][0], axes[2][1], axes[1][2], axes[0][3]]

In [152]: df.plot(subplots=True, ax=target1, legend=False, sharex=False, sharey=False);

In [153]: (-df).plot(subplots=True, ax=target2, legend=False, sharex=False, sharey=False);
```

Another option is passing an `ax` argument to `Series.plot()` to plot on a particular axis:

```
In [154]: fig, axes = plt.subplots(nrows=2, ncols=2)
```

```
In [155]: plt.subplots_adjust(wspace=0.2, hspace=0.5)
```

```
In [156]: df["A"].plot(ax=axes[0, 0]);
```

```
In [157]: axes[0, 0].set_title("A");
```

```
In [158]: df["B"].plot(ax=axes[0, 1]);
```

```
In [159]: axes[0, 1].set_title("B");
```

(continues on next page)

(continued from previous page)

```
In [160]: df["C"].plot(ax=axes[1, 0]);
In [161]: axes[1, 0].set_title("C");
In [162]: df["D"].plot(ax=axes[1, 1]);
In [163]: axes[1, 1].set_title("D");
```

Plotting with error bars

Plotting with error bars is supported in `DataFrame.plot()` and `Series.plot()`.

Horizontal and vertical error bars can be supplied to the `xerr` and `yerr` keyword arguments to `plot()`. The error values can be specified using a variety of formats:

- As a `DataFrame` or `dict` of errors with column names matching the `columns` attribute of the plotting `DataFrame` or matching the `name` attribute of the `Series`.
- As a `str` indicating which of the columns of plotting `DataFrame` contain the error values.
- As raw values (`list`, `tuple`, or `np.ndarray`). Must be the same length as the plotting `DataFrame/Series`.

Here is an example of one way to easily plot group means with standard deviations from the raw data.

```
# Generate the data
In [164]: ix3 = pd.MultiIndex.from_arrays(
...:     [
...:         [
...:             ["a", "a", "a", "a", "a", "b", "b", "b", "b", "b"],
...:             ["foo", "foo", "foo", "bar", "bar", "foo", "bar", "bar", "bar", "bar"]
...:         ],
...:         names=["letter", "word"],
...:     ]
...: )

In [165]: df3 = pd.DataFrame(
...:     {
...:         "data1": [9, 3, 2, 4, 3, 2, 4, 6, 3, 2],
...:         "data2": [9, 6, 5, 7, 5, 4, 5, 6, 5, 1],
...:     },
...:     index=ix3,
...: )
...:

# Group by index labels and take the means and standard deviations
# for each group
In [166]: gp3 = df3.groupby(level=("letter", "word"))

In [167]: means = gp3.mean()

In [168]: errors = gp3.std()

In [169]: means
Out[169]:
      data1    data2
letter word
a      bar  3.500000  6.000000
       foo  4.666667  6.666667
b      bar  3.666667  4.000000
       foo  3.000000  4.500000

In [170]: errors
Out[170]:
      data1    data2
letter word
a      bar  0.707107  1.414214
       foo  3.785939  2.081666
b      bar  2.081666  2.645751
       foo  1.414214  0.707107

# Plot
In [171]: fig, ax = plt.subplots()

In [172]: means.plot.bar(yerr=errors, ax=ax, capsize=4, rot=0);
```

Asymmetrical error bars are also supported, however raw error values must be provided in this case. For a N length Series, a 2xN array should be provided indicating lower and upper (or left and right) errors. For a MxN DataFrame, asymmetrical errors should be in a Mx2xN array.

Here is an example of one way to plot the min/max range using asymmetrical error bars.

```
In [173]: mins = gp3.min()
In [174]: maxs = gp3.max()

# errors should be positive, and defined in the order of lower, upper
In [175]: errors = [[means[c] - mins[c], maxs[c] - means[c]] for c in df3.columns]

# Plot
In [176]: fig, ax = plt.subplots()

In [177]: means.plot.bar(yerr=errors, ax=ax, capsize=4, rot=0);
```

Plotting tables

Plotting with matplotlib table is now supported in `DataFrame.plot()` and `Series.plot()` with a `table` keyword. The `table` keyword can accept `bool`, `DataFrame` or `Series`. The simple way to draw a table is to specify `table=True`. Data will be transposed to meet matplotlib's default layout.

```
In [178]: fig, ax = plt.subplots(1, 1, figsize=(7, 6.5))
```

```
In [179]: df = pd.DataFrame(np.random.rand(5, 3), columns=["a", "b", "c"])
```

```
In [180]: ax.xaxis.tick_top() # Display x-axis ticks on top.
```

```
In [181]: df.plot(table=True, ax=ax);
```

Also, you can pass a different DataFrame or Series to the `table` keyword. The data will be drawn as displayed in print method (not transposed automatically). If required, it should be transposed manually as seen in the example below.

```
In [182]: fig, ax = plt.subplots(1, 1, figsize=(7, 6.75))
```

```
In [183]: ax.xaxis.tick_top() # Display x-axis ticks on top.
```

```
In [184]: df.plot(table=np.round(df.T, 2), ax=ax);
```

There also exists a helper function `pandas.plotting.table`, which creates a table from DataFrame or Series, and adds it to an `matplotlib.Axes` instance. This function can accept keywords which the `matplotlib.table` has.

```
In [185]: from pandas.plotting import table
```

```
In [186]: fig, ax = plt.subplots(1, 1)
```

```
In [187]: table(ax, np.round(df.describe(), 2), loc="upper right", colWidths=[0.2, 0.2, 0.2]);
```

```
In [188]: df.plot(ax=ax, ylim=(0, 2), legend=None);
```

Note: You can get table instances on the axes using `axes.tables` property for further decorations. See the [matplotlib table documentation](#) for more.

Colormaps

A potential issue when plotting a large number of columns is that it can be difficult to distinguish some series due to repetition in the default colors. To remedy this, `DataFrame` plotting supports the use of the `colormap` argument, which accepts either a Matplotlib colormap or a string that is a name of a colormap registered with Matplotlib. A visualization of the default matplotlib colormaps is available [here](#).

As matplotlib does not directly support colormaps for line-based plots, the colors are selected based on an even spacing determined by the number of columns in the `DataFrame`. There is no consideration made for background color, so some colormaps will produce lines that are not easily visible.

To use the cubehelix colormap, we can pass `colormap='cubehelix'`.

```
In [189]: df = pd.DataFrame(np.random.randn(1000, 10), index=ts.index)

In [190]: df = df.cumsum()

In [191]: plt.figure();

In [192]: df.plot(colormap="cubehelix");
```

Alternatively, we can pass the colormap itself:

```
In [193]: from matplotlib import cm  
  
In [194]: plt.figure();  
  
In [195]: df.plot(colormap=cm.cubehelix);
```

Colormaps can also be used other plot types, like bar charts:

```
In [196]: dd = pd.DataFrame(np.random.randn(10, 10)).applymap(abs)
```

```
In [197]: dd = dd.cumsum()
```

```
In [198]: plt.figure();
```

```
In [199]: dd.plot.bar(colormap="Greens");
```

Parallel coordinates charts:

```
In [200]: plt.figure();
```

```
In [201]: parallel_coordinates(data, "Name", colormap="gist_rainbow");
```

Andrews curves charts:

```
In [202]: plt.figure();
```

```
In [203]: andrews_curves(data, "Name", colormap="winter");
```

2.15.6 Plotting directly with matplotlib

In some situations it may still be preferable or necessary to prepare plots directly with matplotlib, for instance when a certain type of plot or customization is not (yet) supported by pandas. Series and DataFrame objects behave like arrays and can therefore be passed directly to matplotlib functions without explicit casts.

pandas also automatically registers formatters and locators that recognize date indices, thereby extending date and time support to practically all plot types available in matplotlib. Although this formatting does not provide the same level of refinement you would get when plotting via pandas, it can be faster when plotting a large number of points.

```
In [204]: price = pd.Series(
.....:     np.random.randn(150).cumsum(),
.....:     index=pd.date_range("2000-1-1", periods=150, freq="B"),
.....: )
.....:

In [205]: ma = price.rolling(20).mean()

In [206]: mstd = price.rolling(20).std()

In [207]: plt.figure();
```

(continues on next page)

(continued from previous page)

```
In [208]: plt.plot(price.index, price, "k");
In [209]: plt.plot(ma.index, ma, "b");
In [210]: plt.fill_between(mstd.index, ma - 2 * mstd, ma + 2 * mstd, color="b", alpha=0.
                           ↵2);
```

2.15.7 Plotting backends

Starting in version 0.25, pandas can be extended with third-party plotting backends. The main idea is letting users select a plotting backend different than the provided one based on Matplotlib.

This can be done by passing ‘backend.module’ as the argument `backend` in `plot` function. For example:

```
>>> Series([1, 2, 3]).plot(backend="backend.module")
```

Alternatively, you can also set this option globally, do you don’t need to specify the keyword in each `plot` call. For example:

```
>>> pd.set_option("plotting.backend", "backend.module")
>>> pd.Series([1, 2, 3]).plot()
```

Or:

```
>>> pd.options.plotting.backend = "backend.module"
>>> pd.Series([1, 2, 3]).plot()
```

This would be more or less equivalent to:

```
>>> import backend.module
>>> backend.module.plot(pd.Series([1, 2, 3]))
```

The backend module can then use other visualization tools (Bokeh, Altair, hvplot,...) to generate the plots. Some libraries implementing a backend for pandas are listed on the ecosystem ecosystem.visualization page.

Developers guide can be found at <https://pandas.pydata.org/docs/dev/development/extending.html#plotting-backends>

2.16 Table Visualization

This section demonstrates visualization of tabular data using the *Styler* class. For information on visualization with charting please see [Chart Visualization](#). This document is written as a Jupyter Notebook, and can be viewed or downloaded [here](#).

2.16.1 Styler Object and HTML

Styling should be performed after the data in a DataFrame has been processed. The *Styler* creates an HTML <table> and leverages CSS styling language to manipulate many parameters including colors, fonts, borders, background, etc. See [here](#) for more information on styling HTML tables. This allows a lot of flexibility out of the box, and even enables web developers to integrate DataFrames into their exiting user interface designs.

The DataFrame.style attribute is a property that returns a *Styler* object. It has a `_repr_html_` method defined on it so they are rendered automatically in Jupyter Notebook.

```
[2]: import pandas as pd
import numpy as np
import matplotlib as mpl

df = pd.DataFrame([[38.0, 2.0, 18.0, 22.0, 21, np.nan], [19, 439, 6, 452, 226, 232]],
                  index=pd.Index(['Tumour (Positive)', 'Non-Tumour (Negative)'], name=
→'Actual Label:'),
                  columns=pd.MultiIndex.from_product([[['Decision Tree', 'Regression',
→'Random'], ['Tumour', 'Non-Tumour']]], names=['Model:', 'Predicted:']))
df.style
```

[2]: <pandas.io.formats.style.Styler at 0x7f417c593d00>

The above output looks very similar to the standard DataFrame HTML representation. But the HTML here has already attached some CSS classes to each cell, even if we haven't yet created any styles. We can view these by calling the `.to_html()` method, which returns the raw HTML as string, which is useful for further processing or adding to a file - read on in [More about CSS and HTML](#). Below we will show how we can use these to format the DataFrame to be more communicative. For example how we can build s:

```
[4]: s
[4]: <pandas.io.formats.style.Styler at 0x7f420556dbb0>
```

2.16.2 Formatting the Display

Formatting Values

Before adding styles it is useful to show that the *Styler* can distinguish the *display* value from the *actual* value, in both datavlaues and index or columns headers. To control the display value, the text is printed in each cell as string, and we can use the `.format()` and `.format_index()` methods to manipulate this according to a `format spec string` or a callable that takes a single value and returns a string. It is possible to define this for the whole table, or index, or for individual columns, or MultiIndex levels.

Additionally, the `format` function has a **precision** argument to specifically help formatting floats, as well as **decimal** and **thousands** separators to support other locales, an **na_rep** argument to display missing data, and an **escape** argument to help displaying safe-HTML or safe-LaTeX. The default formatter is configured to adopt pandas' `styler.format.precision` option, controllable using `pd.option_context('format.precision', 2)`:

```
[5]: df.style.format(precision=0, na_rep='MISSING', thousands=" ",
                   formatter={'Decision Tree', 'Tumour'): "{:.2f}",
                               ('Regression', 'Non-Tumour'): lambda x: "$ {:.1f}".format(x*-
→1e6)
                })
[5]: <pandas.io.formats.style.Styler at 0x7f4205552b80>
```

Using Styler to manipulate the display is a useful feature because maintaining the indexing and datavalues for other purposes gives greater control. You do not have to overwrite your DataFrame to display it how you like. Here is an example of using the formatting functions whilst still relying on the underlying data for indexing and calculations.

```
[6]: weather_df = pd.DataFrame(np.random.rand(10,2)*5,
                               index=pd.date_range(start="2021-01-01", periods=10),
                               columns=["Tokyo", "Beijing"])

def rain_condition(v):
    if v < 1.75:
        return "Dry"
    elif v < 2.75:
        return "Rain"
    return "Heavy Rain"

def make_pretty(styler):
    styler.set_caption("Weather Conditions")
    styler.format(rain_condition)
    styler.format_index(lambda v: v.strftime("%A"))
    styler.background_gradient(axis=None, vmin=1, vmax=5, cmap="YlGnBu")
    return styler
```

weather_df

	Tokyo	Beijing

```

Hiding Data

The index and column headers can be completely hidden, as well subselecting rows or columns that one wishes to exclude. Both these options are performed using the same methods.

The index can be hidden from rendering by calling `.hide()` without any arguments, which might be useful if your index is integer based. Similarly column headers can be hidden by calling `.hide(axis="columns")` without any further arguments.

Specific rows or columns can be hidden from rendering by calling the same `.hide()` method and passing in a row/column label, a list-like or a slice of row/column labels to for the subset argument.

Hiding does not change the integer arrangement of CSS classes, e.g. hiding the first two columns of a DataFrame means the column class indexing will still start at col2, since col0 and col1 are simply ignored.

We can update our Styler object from before to hide some data and format the values.

```
[8]: s = df.style.format('{:0f}').hide([('Random', 'Tumour'), ('Random', 'Non-Tumour')],  
    axis="columns")
```

```
s
```

```
[8]: <pandas.io.formats.style.Styler at 0x7f417c593790>
```

2.16.3 Methods to Add Styles

There are **3 primary methods of adding custom CSS styles** to `Styler`:

- Using `.set_table_styles()` to control broader areas of the table with specified internal CSS. Although table styles allow the flexibility to add CSS selectors and properties controlling all individual parts of the table, they are unwieldy for individual cell specifications. Also, note that table styles cannot be exported to Excel.
- Using `.set_td_classes()` to directly link either external CSS classes to your data cells or link the internal CSS classes created by `.set_table_styles()`. See [here](#). These cannot be used on column header rows or indexes, and also won't export to Excel.
- Using the `.apply()` and `.applymap()` functions to add direct internal CSS to specific data cells. See [here](#). As of v1.4.0 there are also methods that work directly on column header rows or indexes; `.apply_index()` and `.applymap_index()`. Note that only these methods add styles that will export to Excel. These methods work in a similar way to `DataFrame.apply()` and `DataFrame.applymap()`.

2.16.4 Table Styles

Table styles are flexible enough to control all individual parts of the table, including column headers and indexes. However, they can be unwieldy to type for individual data cells or for any kind of conditional formatting, so we recommend that table styles are used for broad styling, such as entire rows or columns at a time.

Table styles are also used to control features which can apply to the whole table at once such as creating a generic hover functionality. The `:hover` pseudo-selector, as well as other pseudo-selectors, can only be used this way.

To replicate the normal format of CSS selectors and properties (attribute value pairs), e.g.

```
tr:hover {  
    background-color: #fffff99;  
}
```

the necessary format to pass styles to `.set_table_styles()` is as a list of dicts, each with a CSS-selector tag and CSS-properties. Properties can either be a list of 2-tuples, or a regular CSS-string, for example:

```
[10]: cell_hover = { # for row hover use <tr> instead of <td>  
    'selector': 'td:hover',  
    'props': [('background-color', '#fffffb3')]  
}  
index_names = {  
    'selector': '.index_name',  
    'props': 'font-style: italic; color: darkgrey; font-weight: normal;'  
}  
headers = {  
    'selector': 'th:not(.index_name)',  
    'props': 'background-color: #000066; color: white;'  
}  
s.set_table_styles([cell_hover, index_names, headers])  
[10]: <pandas.io.formats.style.Styler at 0x7f417c593790>
```

Next we just add a couple more styling artifacts targeting specific parts of the table. Be careful here, since we are *chaining methods* we need to explicitly instruct the method **not to** overwrite the existing styles.

```
[12]: s.set_table_styles([  
    {'selector': 'th.col_heading', 'props': 'text-align: center;'},  
    {'selector': 'th.col_heading.level0', 'props': 'font-size: 1.5em;'},  
    {'selector': 'td', 'props': 'text-align: center; font-weight: bold;'},  
], overwrite=False)  
[12]: <pandas.io.formats.style.Styler at 0x7f417c593790>
```

As a convenience method (*since version 1.2.0*) we can also pass a `dict` to `.set_table_styles()` which contains row or column keys. Behind the scenes Styler just indexes the keys and adds relevant `.col<m>` or `.row<n>` classes as necessary to the given CSS selectors.

```
[14]: s.set_table_styles({  
    ('Regression', 'Tumour'): [{  
        'selector': 'th',  
        'props': 'border-left: 1px solid white  
    }],  
    'td': {  
        'selector': 'td',  
        'props': 'border-left: 1px solid  
    #000066'}]  
}, overwrite=False, axis=0)
```

[14]: <pandas.io.formats.style.Styler at 0x7f417c593790>

2.16.5 Setting Classes and Linking to External CSS

If you have designed a website then it is likely you will already have an external CSS file that controls the styling of table and cell objects within it. You may want to use these native files rather than duplicate all the CSS in python (and duplicate any maintenance work).

Table Attributes

It is very easy to add a `class` to the main `<table>` using `.set_table_attributes()`. This method can also attach inline styles - read more in [CSS Hierarchies](#).

```
[16]: out = s.set_table_attributes('class="my-table-cls"').to_html()
print(out[out.find('<table'):][:109])

<table id="T_xyz01" class="my-table-cls">
    <thead>
        <tr>
            <th class="index_name level0" >Model:</th>
```

Data Cell CSS Classes

New in version 1.2.0

The `.set_td_classes()` method accepts a DataFrame with matching indices and columns to the underlying `Styler`'s DataFrame. That DataFrame will contain strings as css-classes to add to individual data cells: the `<td>` elements of the `<table>`. Rather than use external CSS we will create our classes internally and add them to table style. We will save adding the borders until the *section on tooltips*.

```
[17]: s.set_table_styles([ # create internal CSS classes
    {'selector': '.true', 'props': 'background-color: #e6ffe6;'},
    {'selector': '.false', 'props': 'background-color: #ffe6e6;'},
], overwrite=False)
cell_color = pd.DataFrame([['true', 'false', 'true', 'false'],
                           ['false', 'true', 'false', 'true']],
                           index=df.index,
                           columns=df.columns[:4])
s.set_td_classes(cell_color)

[17]: <pandas.io.formats.style.Styler at 0x7f417c593790>
```

2.16.6 Styler Functions

Acting on Data

We use the following methods to pass your style functions. Both of those methods take a function (and some other keyword arguments) and apply it to the DataFrame in a certain way, rendering CSS styles.

- `.applymap()` (elementwise): accepts a function that takes a single value and returns a string with the CSS attribute-value pair.
- `.apply()` (column-/row-/table-wise): accepts a function that takes a Series or DataFrame and returns a Series, DataFrame, or numpy array with an identical shape where each element is a string with a CSS attribute-value pair. This method passes each column or row of your DataFrame one-at-a-time or the entire table at once, depending on the `axis` keyword argument. For columnwise use `axis=0`, rowwise use `axis=1`, and for the entire table at once use `axis=None`.

This method is powerful for applying multiple, complex logic to data cells. We create a new DataFrame to demonstrate this.

```
[19]: np.random.seed(0)
df2 = pd.DataFrame(np.random.randn(10,4), columns=['A','B','C','D'])
df2.style
```

```
[19]: <pandas.io.formats.style.Styler at 0x7f42044a36d0>
```

For example we can build a function that colors text if it is negative, and chain this with a function that partially fades cells of negligible value. Since this looks at each element in turn we use `applymap`.

```
[20]: def style_negative(v, props=''):
    return props if v < 0 else None
s2 = df2.style.applymap(style_negative, props='color:red;')\
    .applymap(lambda v: 'opacity: 20%;' if (v < 0.3) and (v > -0.3) else None)
s2
```

```
[20]: <pandas.io.formats.style.Styler at 0x7f4205302b80>
```

We can also build a function that highlights the maximum value across rows, cols, and the DataFrame all at once. In this case we use `apply`. Below we highlight the maximum in a column.

```
[22]: def highlight_max(s, props=''):
    return np.where(s == np.nanmax(s.values), props, '')
s2.apply(highlight_max, props='color:white;background-color:darkblue', axis=0)
```

```
[22]: <pandas.io.formats.style.Styler at 0x7f4205302b80>
```

We can use the same function across the different axes, highlighting here the DataFrame maximum in purple, and row maximums in pink.

```
[24]: s2.apply(highlight_max, props='color:white;background-color:pink;', axis=1)\n    .apply(highlight_max, props='color:white;background-color:purple', axis=None)
```

```
[24]: <pandas.io.formats.style.Styler at 0x7f4205302b80>
```

This last example shows how some styles have been overwritten by others. In general the most recent style applied is active but you can read more in the [section on CSS hierarchies](#). You can also apply these styles to more granular parts of the DataFrame - read more in section on [subset slicing](#).

It is possible to replicate some of this functionality using just classes but it can be more cumbersome. See [item 3\) of Optimization](#)

Debugging Tip: If you're having trouble writing your style function, try just passing it into DataFrame.apply. Internally, Styler.apply uses DataFrame.apply so the result should be the same, and with DataFrame.apply you will be able to inspect the CSS string output of your intended function in each cell.

Acting on the Index and Column Headers

Similar application is achieved for headers by using:

- `.applymap_index()` (elementwise): accepts a function that takes a single value and returns a string with the CSS attribute-value pair.
- `.apply_index()` (level-wise): accepts a function that takes a Series and returns a Series, or numpy array with an identical shape where each element is a string with a CSS attribute-value pair. This method passes each level of your Index one-at-a-time. To style the index use `axis=0` and to style the column headers use `axis=1`.

You can select a level of a MultiIndex but currently no similar subset application is available for these methods.

```
[26]: s2.applymap_index(lambda v: "color:pink;" if v>4 else "color:darkblue;", axis=0)
s2.apply_index(lambda s: np.where(s.isin(["A", "B"])), "color:pink;", "color:darkblue;"), ↴
axis=1)

[26]: <pandas.io.formats.style.Styler at 0x7f4205302b80>
```

2.16.7 Tooltips and Captions

Table captions can be added with the `.set_caption()` method. You can use table styles to control the CSS relevant to the caption.

```
[27]: s.set_caption("Confusion matrix for multiple cancer prediction models.")\
.set_table_styles([{
    'selector': 'caption',
    'props': 'caption-side: bottom; font-size:1.25em;'
}], overwrite=False)

[27]: <pandas.io.formats.style.Styler at 0x7f417c593790>
```

Adding tooltips (*since version 1.3.0*) can be done using the `.set_tooltips()` method in the same way you can add CSS classes to data cells by providing a string based DataFrame with intersecting indices and columns. You don't have to specify a `css_class` name or any css props for the tooltips, since there are standard defaults, but the option is there if you want more visual control.

```
[29]: tt = pd.DataFrame(['This model has a very strong true positive rate',
                      "This model's total number of false negatives is too high"],
                     index=['Tumour (Positive)'], columns=df.columns[[0,3]])
s.set_tooltips(tt, props='visibility: hidden; position: absolute; z-index: 1; border: 1px solid #000066; '
                           'background-color: white; color: #000066; font-size: 0.8em; '
                           'transform: translate(0px, -24px); padding: 0.6em; border-radius: 0.5em;')

[29]: <pandas.io.formats.style.Styler at 0x7f417c593790>
```

The only thing left to do for our table is to add the highlighting borders to draw the audience attention to the tooltips. We will create internal CSS classes as before using table styles. **Setting classes always overwrites** so we need to make sure we add the previous classes.

```
[31]: s.set_table_styles([
    # create internal CSS classes
    {'selector': '.border-red', 'props': 'border: 2px dashed red;'},
    {'selector': '.border-green', 'props': 'border: 2px dashed green;'},
], overwrite=False)
cell_border = pd.DataFrame([['border-green', ' ', ' ', 'border-red'],
                            [' ', ' ', ' ', ' ']],
                           index=df.index,
                           columns=df.columns[:4])
s.set_td_classes(cell_color + cell_border)

[31]: <pandas.io.formats.style.Styler at 0x7f417c593790>
```

2.16.8 Finer Control with Slicing

The examples we have shown so far for the `Styler.apply` and `Styler.applymap` functions have not demonstrated the use of the `subset` argument. This is a useful argument which permits a lot of flexibility: it allows you to apply styles to specific rows or columns, without having to code that logic into your `style` function.

The value passed to `subset` behaves similar to slicing a DataFrame:

- A scalar is treated as a column label
- A list (or Series or NumPy array) is treated as multiple column labels
- A tuple is treated as `(row_indexer, column_indexer)`

Consider using `pd.IndexSlice` to construct the tuple for the last one. We will create a MultiIndexed DataFrame to demonstrate the functionality.

```
[33]: df3 = pd.DataFrame(np.random.randn(4,4),
                      pd.MultiIndex.from_product([['A', 'B'], ['r1', 'r2']]),
                      columns=['c1', 'c2', 'c3', 'c4'])
df3

[33]:      c1      c2      c3      c4
A r1 -1.048553 -1.420018 -1.706270  1.950775
          r2 -0.509652 -0.438074 -1.252795  0.777490
B r1 -1.613898 -0.212740 -0.895467  0.386902
          r2 -0.510805 -1.180632 -0.028182  0.428332
```

We will use `subset` to highlight the maximum in the third and fourth columns with red text. We will highlight the subset sliced region in yellow.

```
[34]: slice_ = ['c3', 'c4']
df3.style.apply(highlight_max, props='color:red;', axis=0, subset=slice_) \
    .set_properties(**{'background-color': '#ffffb3'}, subset=slice_)

[34]: <pandas.io.formats.style.Styler at 0x7f4205313250>
```

If combined with the `IndexSlice` as suggested then it can index across both dimensions with greater flexibility.

```
[35]: idx = pd.IndexSlice
slice_ = idx[idx[:, 'r1'], idx['c2':'c4']]
df3.style.apply(highlight_max, props='color:red;', axis=0, subset=slice_)\
    .set_properties(**{'background-color': '#ffffb3'}, subset=slice_)

[35]: <pandas.io.formats.style.Styler at 0x7f42053199a0>
```

This also provides the flexibility to sub select rows when used with the `axis=1`.

```
[36]: slice_ = idx[idx[:, 'r2'], :]
df3.style.apply(highlight_max, props='color:red;', axis=1, subset=slice_)\
    .set_properties(**{'background-color': '#ffffb3'}, subset=slice_)

[36]: <pandas.io.formats.style.Styler at 0x7f4205319c40>
```

There is also scope to provide **conditional filtering**.

Suppose we want to highlight the maximum across columns 2 and 4 only in the case that the sum of columns 1 and 3 is less than -2.0 (*essentially excluding rows `(:,'r2')`*).

```
[37]: slice_ = idx[(idx[['c1']] + df3[['c3']]) < -2.0, ['c2', 'c4']]
df3.style.apply(highlight_max, props='color:red;', axis=1, subset=slice_)\
    .set_properties(**{'background-color': '#ffffb3'}, subset=slice_)

[37]: <pandas.io.formats.style.Styler at 0x7f4205319910>
```

Only label-based slicing is supported right now, not positional, and not callables.

If your style function uses a `subset` or `axis` keyword argument, consider wrapping your function in a `functools.partial`, partialing out that keyword.

```
my_func2 = functools.partial(my_func, subset=42)
```

2.16.9 Optimization

Generally, for smaller tables and most cases, the rendered HTML does not need to be optimized, and we don't really recommend it. There are two cases where it is worth considering:

- If you are rendering and styling a very large HTML table, certain browsers have performance issues.
- If you are using `Styler` to dynamically create part of online user interfaces and want to improve network performance.

Here we recommend the following steps to implement:

1. Remove UUID and cell_ids

Ignore the `uuid` and set `cell_ids` to `False`. This will prevent unnecessary HTML.

This is sub-optimal:

```
[38]: df4 = pd.DataFrame([[1,2],[3,4]])
s4 = df4.style
```

This is better:

```
[39]: from pandas.io.formats.style import Styler  
s4 = Styler(df4, uuid_len=0, cell_ids=False)
```

2. Use table styles

Use table styles where possible (e.g. for all cells or rows or columns at a time) since the CSS is nearly always more efficient than other formats.

This is sub-optimal:

```
[40]: props = 'font-family: "Times New Roman", Times, serif; color: #e83e8c; font-size:1.3em;'  
df4.style.applymap(lambda x: props, subset=[1])  
[40]: <pandas.io.formats.style.Styler at 0x7f4205313df0>
```

This is better:

```
[41]: df4.style.set_table_styles([{'selector': 'td.col1', 'props': props}])  
[41]: <pandas.io.formats.style.Styler at 0x7f420556c520>
```

3. Set classes instead of using Styler functions

For large DataFrames where the same style is applied to many cells it can be more efficient to declare the styles as classes and then apply those classes to data cells, rather than directly applying styles to cells. It is, however, probably still easier to use the Styler function api when you are not concerned about optimization.

This is sub-optimal:

```
[42]: df2.style.apply(highlight_max, props='color:white;background-color:darkblue;', axis=0)\  
      .apply(highlight_max, props='color:white;background-color:pink;', axis=1)\  
      .apply(highlight_max, props='color:white;background-color:purple', axis=None)  
[42]: <pandas.io.formats.style.Styler at 0x7f42053138b0>
```

This is better:

```
[43]: build = lambda x: pd.DataFrame(x, index=df2.index, columns=df2.columns)  
cls1 = build(df2.apply(highlight_max, props='cls-1 ', axis=0))  
cls2 = build(df2.apply(highlight_max, props='cls-2 ', axis=1, result_type='expand').  
            values)  
cls3 = build(highlight_max(df2, props='cls-3 '))
```

(continues on next page)

(continued from previous page)

```
df2.style.set_table_styles([
    {'selector': '.cls-1', 'props': 'color:white;background-color:darkblue;'},
    {'selector': '.cls-2', 'props': 'color:white;background-color:pink;'},
    {'selector': '.cls-3', 'props': 'color:white;background-color:purple;'}
]).set_td_classes(cls1 + cls2 + cls3)
```

[43]: <pandas.io.formats.style.Styler at 0x7f42052b4760>

4. Don't use tooltips

Tooltips require `cell_ids` to work and they generate extra HTML elements for *every* data cell.

5. If every byte counts use string replacement

You can remove unnecessary HTML, or shorten the default class names by replacing the default css dict. You can read a little more about CSS *below*.

```
[44]: my_css = {
    "row_heading": "",
    "col_heading": "",
    "index_name": "",
    "col": "c",
    "row": "r",
    "col_trim": "",
    "row_trim": "",
    "level": "l",
    "data": "",
    "blank": ""
}
html = Styler(df4, uuid_len=0, cell_ids=False)
html.set_table_styles([{'selector': 'td', 'props': props},
                      {'selector': '.c1', 'props': 'color:green;'},
                      {'selector': '.l0', 'props': 'color:blue;'}],
                      css_class_names=my_css)
print(html.to_html())
<style type="text/css">
#T_ td {
    font-family: "Times New Roman", Times, serif;
    color: #e83e8c;
    font-size: 1.3em;
}
#T_ .c1 {
    color: green;
}
#T_ .l0 {
    color: blue;
}
</style>
<table id="T_">
    <thead>
```

(continues on next page)

(continued from previous page)

```
<tr>
    <th class=" l0" >&nbsp;</th>
    <th class=" l0 c0" >0</th>
    <th class=" l0 c1" >1</th>
</tr>
</thead>
<tbody>
    <tr>
        <th class=" l0 r0" >0</th>
        <td class=" r0 c0" >1</td>
        <td class=" r0 c1" >2</td>
    </tr>
    <tr>
        <th class=" l0 r1" >1</th>
        <td class=" r1 c0" >3</td>
        <td class=" r1 c1" >4</td>
    </tr>
</tbody>
</table>
```

[45]: `html`[45]: `<pandas.io.formats.style.Styler at 0x7f420556ca00>`

2.16.10 Builtin Styles

Some styling functions are common enough that we've "built them in" to the `Styler`, so you don't have to write them and apply them yourself. The current list of such functions is:

- `.highlight_null`: for use with identifying missing data.
- `.highlight_min` and `.highlight_max`: for use with identifying extremities in data.
- `.highlight_between` and `.highlight_quantile`: for use with identifying classes within data.
- `.background_gradient`: a flexible method for highlighting cells based on their, or other, values on a numeric scale.
- `.text_gradient`: similar method for highlighting text based on their, or other, values on a numeric scale.
- `.bar`: to display mini-charts within cell backgrounds.

The individual documentation on each function often gives more examples of their arguments.

Highlight Null

```
[46]: df2.iloc[0,2] = np.nan
df2.iloc[4,3] = np.nan
df2.loc[:4].style.highlight_null(null_color='yellow')
```

[46]: `<pandas.io.formats.style.Styler at 0x7f4205319d90>`

Highlight Min or Max

```
[47]: df2.loc[:4].style.highlight_max(axis=1, props='color:white; font-weight:bold; background-color:darkblue;')

[47]: <pandas.io.formats.style.Styler at 0x7f4205319fa0>
```

Highlight Between

This method accepts ranges as float, or NumPy arrays or Series provided the indexes match.

```
[48]: left = pd.Series([1.0, 0.0, 1.0], index=["A", "B", "D"])
df2.loc[:4].style.highlight_between(left=left, right=1.5, axis=1, props='color:white; background-color:purple;')

[48]: <pandas.io.formats.style.Styler at 0x7f42052b4e50>
```

Highlight Quantile

Useful for detecting the highest or lowest percentile values

```
[49]: df2.loc[:4].style.highlight_quantile(q_left=0.85, axis=None, color='yellow')

[49]: <pandas.io.formats.style.Styler at 0x7f42052b5580>
```

Background Gradient and Text Gradient

You can create “heatmaps” with the `background_gradient` and `text_gradient` methods. These require matplotlib, and we’ll use Seaborn to get a nice colormap.

```
[50]: import seaborn as sns
cm = sns.light_palette("green", as_cmap=True)

df2.style.background_gradient(cmap=cm)

[50]: <pandas.io.formats.style.Styler at 0x7f42052f6ac0>
```

```
[51]: df2.style.text_gradient(cmap=cm)

[51]: <pandas.io.formats.style.Styler at 0x7f42053136d0>
```

`.background_gradient` and `.text_gradient` have a number of keyword arguments to customise the gradients and colors. See the documentation.

Set properties

Use Styler.set_properties when the style doesn't actually depend on the values. This is just a simple wrapper for .applymap where the function returns the same properties for all cells.

```
[52]: df2.loc[:4].style.set_properties(**{'background-color': 'black',
                                         'color': 'lawngreen',
                                         'border-color': 'white'})
```

```
[52]: <pandas.io.formats.style.Styler at 0x7f420556d310>
```

Bar charts

You can include “bar charts” in your DataFrame.

```
[53]: df2.style.bar(subset=['A', 'B'], color='#d65f5f')
```

```
[53]: <pandas.io.formats.style.Styler at 0x7f41da19d520>
```

Additional keyword arguments give more control on centering and positioning, and you can pass a list of [color_negative, color_positive] to highlight lower and higher values or a matplotlib colormap.

To showcase an example here's how you can change the above with the new align option, combined with setting vmin and vmax limits, the width of the figure, and underlying css props of cells, leaving space to display the text and the bars. We also use text_gradient to color the text the same as the bars using a matplotlib colormap (although in this case the visualization is probably better without this additional effect).

```
[54]: df2.style.format('{:.3f}', na_rep='')\n        .bar(align=0, vmin=-2.5, vmax=2.5, cmap="bwr", height=50,\n              width=60, props="width: 120px; border-right: 1px solid black;")\n        .text_gradient(cmap="bwr", vmin=-2.5, vmax=2.5)
```

```
[54]: <pandas.io.formats.style.Styler at 0x7f41da19eac0>
```

The following example aims to give a highlight of the behavior of the new align options:

```
[56]: HTML(head)
```

```
[56]: <IPython.core.display.HTML object>
```

2.16.11 Sharing styles

Say you have a lovely style built up for a DataFrame, and now you want to apply the same style to a second DataFrame. Export the style with df1.style.export, and import it on the second DataFrame with df1.style.set

```
[57]: style1 = df2.style\\n        .applymap(style_negative, props='color:red;')\\n        .applymap(lambda v: 'opacity: 20%;' if (v < 0.3) and (v > -0.3) else None)\\n        .set_table_styles([{"selector": "th", "props": "color: blue;"}])\\n        .hide(axis="index")
```

```
style1
```

```
[57]: <pandas.io.formats.style.Styler at 0x7f41da15fdc0>
```

```
[58]: style2 = df3.style
style2.use(style1.export())
style2

[58]: <pandas.io.formats.style.Styler at 0x7f41da15f7f0>
```

Notice that you're able to share the styles even though they're data aware. The styles are re-evaluated on the new DataFrame they've been used upon.

2.16.12 Limitations

- DataFrame only (use `Series.to_frame().style`)
- The index and columns do not need to be unique, but certain styling functions can only work with unique indexes.
- No large repr, and construction performance isn't great; although we have some *HTML optimizations*
- You can only apply styles, you can't insert new HTML entities, except via subclassing.

2.16.13 Other Fun and Useful Stuff

Here are a few interesting examples.

Widgets

Styler interacts pretty well with widgets. If you're viewing this online instead of running the notebook yourself, you're missing out on interactively adjusting the color palette.

```
[59]: from ipywidgets import widgets
@widgets.interact
def f(h_neg=(0, 359, 1), h_pos=(0, 359), s=(0., 99.9), l=(0., 99.9)):
    return df2.style.background_gradient(
        cmap=sns.palettes.diverging_palette(h_neg=h_neg, h_pos=h_pos, s=s, l=l,
                                             as_cmap=True)
    )

interactive(children=(IntSlider(value=179, description='h_neg', max=359), IntSlider(value=179, description='h_...'))
```

Magnify

```
[60]: def magnify():
    return [dict(selector="th",
                 props=[("font-size", "4pt")]),
            dict(selector="td",
                 props=[('padding', "0em 0em")]),
            dict(selector="th:hover",
                 props=[("font-size", "12pt")]),
            dict(selector="tr:hover td:hover",
                 props=[('max-width', '200px'),
                       ('font-size', '12pt')])
    ]
```

```
[61]: np.random.seed(25)
cmap = cmap=sns.diverging_palette(5, 250, as_cmap=True)
bigdf = pd.DataFrame(np.random.randn(20, 25)).cumsum()

bigdf.style.background_gradient(cmap, axis=1) \
    .set_properties(**{'max-width': '80px', 'font-size': '1pt'}) \
    .set_caption("Hover to magnify") \
    .format(precision=2) \
    .set_table_styles(magnify())
```

```
[61]: <pandas.io.formats.style.Styler at 0x7f42053195b0>
```

Sticky Headers

If you display a large matrix or DataFrame in a notebook, but you want to always see the column and row headers you can use the `.set_sticky` method which manipulates the table styles CSS.

```
[62]: bigdf = pd.DataFrame(np.random.randn(16, 100))
bigdf.style.set_sticky(axis="index")
```

```
[62]: <pandas.io.formats.style.Styler at 0x7f41da1ba0a0>
```

It is also possible to stick MultiIndexes and even only specific levels.

```
[63]: bigdf.index = pd.MultiIndex.from_product([[["A", "B"], [0, 1], [0, 1, 2, 3]]])
bigdf.style.set_sticky(axis="index", pixel_size=18, levels=[1, 2])
```

```
[63]: <pandas.io.formats.style.Styler at 0x7f42053135b0>
```

HTML Escaping

Suppose you have to display HTML within HTML, that can be a bit of pain when the renderer can't distinguish. You can use the `escape` formatting option to handle this, and even use it within a formatter that contains HTML itself.

```
[64]: df4 = pd.DataFrame([['<div></div>', '&other', '<span></span>']])
df4.style
```

```
[64]: <pandas.io.formats.style.Styler at 0x7f41da15c850>
```

```
[65]: df4.style.format(escape="html")
```

```
[65]: <pandas.io.formats.style.Styler at 0x7f41da121c70>
```

```
[66]: df4.style.format('<a href="https://pandas.pydata.org" target="_blank">{}</a>', escape=
    ↴ "html")
```

```
[66]: <pandas.io.formats.style.Styler at 0x7f41da15c3d0>
```

2.16.14 Export to Excel

Some support (*since version 0.20.0*) is available for exporting styled DataFrames to Excel worksheets using the OpenPyXL or XlsxWriter engines. CSS2.2 properties handled include:

- background-color
- color
- font-family
- font-style
- font-weight
- text-align
- text-decoration
- vertical-align
- white-space: nowrap
- Currently broken: border-style, border-width, border-color and their {top, right, bottom, left} variants}
- Only CSS2 named colors and hex colors of the form #rgb or #rrggbb are currently supported.
- The following pseudo CSS properties are also available to set excel specific style properties:
 - number-format

Table level styles, and data cell CSS-classes are not included in the export to Excel: individual cells must have their properties mapped by the Styler.apply and/or Styler.applymap methods.

```
[67]: df2.style.\n    applymap(style_negative, props='color:red;').\\n    highlight_max(axis=0).\\n    to_excel('styled.xlsx', engine='openpyxl')
```

A screenshot of the output:

	A	B	C	D	E	F
1	A	B	C	D	E	
2	0	1	1.329212		-0.31628	-0.99081
3	1	2	-1.070816	-1.438713	0.564417	0.295722
4	2	3	-1.626404	0.219565	0.678805	1.889273
5	3	4	0.961538	0.104011	-0.481165	0.850229
6	4	5	1.453425	1.057737	0.165562	0.515018
7	5	6	-1.336936	0.562861	1.392855	-0.063328
8	6	7	0.121668	1.207603	-0.00204	1.627796
9	7	8	0.354493	1.037528	-0.385684	0.519818
10	8	9	1.686583	-1.325963	1.428984	-2.089354
11	9	10	-0.12982	0.631523	-0.586538	0.29072

2.16.15 Export to LaTeX

There is support (*since version 1.3.0*) to export Styler to LaTeX. The documentation for the `.to_latex` method gives further detail and numerous examples.

2.16.16 More About CSS and HTML

Cascading Style Sheet (CSS) language, which is designed to influence how a browser renders HTML elements, has its own peculiarities. It never reports errors: it just silently ignores them and doesn't render your objects how you intend so can sometimes be frustrating. Here is a very brief primer on how Styler creates HTML and interacts with CSS, with advice on common pitfalls to avoid.

CSS Classes and Ids

The precise structure of the CSS `class` attached to each cell is as follows.

- Cells with Index and Column names include `index_name` and `level<k>` where `k` is its level in a MultiIndex
- Index label cells include
 - `row_heading`
 - `level<k>` where `k` is the level in a MultiIndex
 - `row<m>` where `m` is the numeric position of the row
- Column label cells include
 - `col_heading`
 - `level<k>` where `k` is the level in a MultiIndex
 - `col<n>` where `n` is the numeric position of the column
- Data cells include
 - `data`
 - `row<m>`, where `m` is the numeric position of the cell.
 - `col<n>`, where `n` is the numeric position of the cell.
- Blank cells include `blank`
- Trimmed cells include `col_trim` or `row_trim`

The structure of the `id` is `T_uuid_level<k>_row<m>_col<n>` where `level<k>` is used only on headings, and headings will only have either `row<m>` or `col<n>` whichever is needed. By default we've also prepended each row/column identifier with a UUID unique to each DataFrame so that the style from one doesn't collide with the styling from another within the same notebook or page. You can read more about the use of UUIDs in [Optimization](#).

We can see example of the HTML by calling the `.to_html()` method.

```
[68]: print(pd.DataFrame([[1,2],[3,4]], index=['i1', 'i2'], columns=['c1', 'c2']).style.to_
.html())
```

```
<style type="text/css">
</style>
<table id="T_60ca3">
  <thead>
    <tr>
```

(continues on next page)

(continued from previous page)

```

<th class="blank level0" >&nbsp;</th>
<th id="T_60ca3_level0_col0" class="col_heading level0 col0" >c1</th>
<th id="T_60ca3_level0_col1" class="col_heading level0 col1" >c2</th>
</tr>
</thead>
<tbody>
<tr>
<th id="T_60ca3_level0_row0" class="row_heading level0 row0" >i1</th>
<td id="T_60ca3_row0_col0" class="data row0 col0" >1</td>
<td id="T_60ca3_row0_col1" class="data row0 col1" >2</td>
</tr>
<tr>
<th id="T_60ca3_level0_row1" class="row_heading level0 row1" >i2</th>
<td id="T_60ca3_row1_col0" class="data row1 col0" >3</td>
<td id="T_60ca3_row1_col1" class="data row1 col1" >4</td>
</tr>
</tbody>
</table>

```

CSS Hierarchies

The examples have shown that when CSS styles overlap, the one that comes last in the HTML render, takes precedence. So the following yield different results:

```
[69]: df4 = pd.DataFrame([['text']])
df4.style.applymap(lambda x: 'color:green;')\
    .applymap(lambda x: 'color:red;')

[69]: <pandas.io.formats.style.Styler at 0x7f41da1ba1f0>

[70]: df4.style.applymap(lambda x: 'color:red;')\
    .applymap(lambda x: 'color:green;')

[70]: <pandas.io.formats.style.Styler at 0x7f41c91cd340>
```

This is only true for CSS rules that are equivalent in hierarchy, or importance. You can read more about [CSS specificity here](#) but for our purposes it suffices to summarize the key points:

A CSS importance score for each HTML element is derived by starting at zero and adding:

- 1000 for an inline style attribute
- 100 for each ID
- 10 for each attribute, class or pseudo-class
- 1 for each element name or pseudo-element

Let's use this to describe the action of the following configurations

```
[71]: df4.style.set_uuid('a_')\
    .set_table_styles([{ 'selector': 'td', 'props': 'color:red;' }])\
    .applymap(lambda x: 'color:green;')
```

```
[71]: <pandas.io.formats.style.Styler at 0x7f41c916c520>
```

This text is red because the generated selector `#T_a_ td` is worth 101 (ID plus element), whereas `#T_a_row0_col0` is only worth 100 (ID), so is considered inferior even though in the HTML it comes after the previous.

```
[72]: df4.style.set_uuid('b_')\
        .set_table_styles([{'selector': 'td', 'props': 'color:red;'},
                          {'selector': '.cls-1', 'props': 'color:blue;'}])\
        .applymap(lambda x: 'color:green;')\
        .set_td_classes(pd.DataFrame([['cls-1']]))
```

```
[72]: <pandas.io.formats.style.Styler at 0x7f41c916ccb0>
```

In the above case the text is blue because the selector `#T_b_ .cls-1` is worth 110 (ID plus class), which takes precedence.

```
[73]: df4.style.set_uuid('c_')\
        .set_table_styles([{'selector': 'td', 'props': 'color:red;'},
                          {'selector': '.cls-1', 'props': 'color:blue;'},
                          {'selector': 'td.data', 'props': 'color:yellow;'}])\
        .applymap(lambda x: 'color:green;')\
        .set_td_classes(pd.DataFrame([['cls-1']]))
```

```
[73]: <pandas.io.formats.style.Styler at 0x7f41c91b6a00>
```

Now we have created another table style this time the selector `T_c_ td.data` (ID plus element plus class) gets bumped up to 111.

If your style fails to be applied, and its really frustrating, try the `!important` trump card.

```
[74]: df4.style.set_uuid('d_')\
        .set_table_styles([{'selector': 'td', 'props': 'color:red;'},
                          {'selector': '.cls-1', 'props': 'color:blue;'},
                          {'selector': 'td.data', 'props': 'color:yellow;'}])\
        .applymap(lambda x: 'color:green !important;')\
        .set_td_classes(pd.DataFrame([['cls-1']]))
```

```
[74]: <pandas.io.formats.style.Styler at 0x7f41da121cd0>
```

Finally got that green text after all!

2.16.17 Extensibility

The core of pandas is, and will remain, its “high-performance, easy-to-use data structures”. With that in mind, we hope that `DataFrame.style` accomplishes two goals

- Provide an API that is pleasing to use interactively and is “good enough” for many tasks
- Provide the foundations for dedicated libraries to build on

If you build a great library on top of this, let us know and we’ll [link](#) to it.

Subclassing

If the default template doesn't quite suit your needs, you can subclass Styler and extend or override the template. We'll show an example of extending the default template to insert a custom header before each table.

```
[75]: from jinja2 import Environment, ChoiceLoader, FileSystemLoader
from IPython.display import HTML
from pandas.io.formats.style import Styler
```

We'll use the following template:

```
[76]: with open("templates/myhtml.tpl") as f:
    print(f.read())

{% extends "html_table.tpl" %}
{% block table %}
<h1>{{ table_title|default("My Table") }}</h1>
{{ super() }}
{% endblock table %}
```

Now that we've created a template, we need to set up a subclass of Styler that knows about it.

```
[77]: class MyStyler(Styler):
    env = Environment(
        loader=ChoiceLoader([
            FileSystemLoader("templates"), # contains ours
            Styler.loader, # the default
        ])
    )
    template_html_table = env.get_template("myhtml.tpl")
```

Notice that we include the original loader in our environment's loader. That's because we extend the original template, so the Jinja environment needs to be able to find it.

Now we can use that custom styler. It's `__init__` takes a DataFrame.

```
[78]: MyStyler(df3)
[78]: <__main__.MyStyler at 0x7f41c91c06d0>
```

Our custom template accepts a `table_title` keyword. We can provide the value in the `.to_html` method.

```
[79]: HTML(MyStyler(df3).to_html(table_title="Extending Example"))
[79]: <IPython.core.display.HTML object>
```

For convenience, we provide the `Styler.from_custom_template` method that does the same as the custom subclass.

```
[80]: EasyStyler = Styler.from_custom_template("templates", "myhtml.tpl")
HTML(EasyStyler(df3).to_html(table_title="Another Title"))
[80]: <IPython.core.display.HTML object>
```

Template Structure

Here's the template structure for both the style generation template and the table generation template:

Style template:

```
[82]: HTML(style_structure)
```

```
[82]: <IPython.core.display.HTML object>
```

Table template:

```
[84]: HTML(table_structure)
```

```
[84]: <IPython.core.display.HTML object>
```

See the template in the [GitHub repo](#) for more details.

2.17 Computational tools

2.17.1 Statistical functions

Percent change

Series and DataFrame have a method `pct_change()` to compute the percent change over a given number of periods (using `fill_method` to fill NA/null values *before* computing the percent change).

```
In [1]: ser = pd.Series(np.random.randn(8))
```

```
In [2]: ser.pct_change()
```

```
Out[2]:
```

```
0          NaN  
1      -1.602976  
2       4.334938

```

Covariance

`Series.cov()` can be used to compute covariance between series (excluding missing values).

```
In [5]: s1 = pd.Series(np.random.randn(1000))
```

```
In [6]: s2 = pd.Series(np.random.randn(1000))
```

```
In [7]: s1.cov(s2)
```

```
Out[7]: 0.0006801088174310875
```

Analogously, `DataFrame.cov()` to compute pairwise covariances among the series in the DataFrame, also excluding NA/null values.

Note: Assuming the missing data are missing at random this results in an estimate for the covariance matrix which is unbiased. However, for many applications this estimate may not be acceptable because the estimated covariance matrix is not guaranteed to be positive semi-definite. This could lead to estimated correlations having absolute values which are greater than one, and/or a non-invertible covariance matrix. See [Estimation of covariance matrices](#) for more details.

```
In [8]: frame = pd.DataFrame(np.random.randn(1000, 5), columns=["a", "b", "c", "d", "e"])
```

```
In [9]: frame.cov()
```

```
Out[9]:
```

	a	b	c	d	e
a	1.000882	-0.003177	-0.002698	-0.006889	0.031912
b	-0.003177	1.024721	0.000191	0.009212	0.000857
c	-0.002698	0.000191	0.950735	-0.031743	-0.005087
d	-0.006889	0.009212	-0.031743	1.002983	-0.047952
e	0.031912	0.000857	-0.005087	-0.047952	1.042487

`DataFrame.cov` also supports an optional `min_periods` keyword that specifies the required minimum number of observations for each column pair in order to have a valid result.

```
In [10]: frame = pd.DataFrame(np.random.randn(20, 3), columns=["a", "b", "c"])
```

```
In [11]: frame.loc[frame.index[:5], "a"] = np.nan
```

```
In [12]: frame.loc[frame.index[5:10], "b"] = np.nan
```

```
In [13]: frame.cov()
```

```
Out[13]:
```

	a	b	c
a	1.123670	-0.412851	0.018169
b	-0.412851	1.154141	0.305260
c	0.018169	0.305260	1.301149

(continues on next page)

(continued from previous page)

```
In [14]: frame.cov(min_periods=12)
Out[14]:
      a          b          c
a  1.123670      NaN  0.018169
b      NaN  1.154141  0.305260
c  0.018169  0.305260  1.301149
```

Correlation

Correlation may be computed using the `corr()` method. Using the `method` parameter, several methods for computing correlations are provided:

Method name	Description
<code>pearson</code> (default)	Standard correlation coefficient
<code>kendall</code>	Kendall Tau correlation coefficient
<code>spearman</code>	Spearman rank correlation coefficient

All of these are currently computed using pairwise complete observations. Wikipedia has articles covering the above correlation coefficients:

- Pearson correlation coefficient
- Kendall rank correlation coefficient
- Spearman's rank correlation coefficient

Note: Please see the [caveats](#) associated with this method of calculating correlation matrices in the [covariance section](#).

```
In [15]: frame = pd.DataFrame(np.random.randn(1000, 5), columns=["a", "b", "c", "d", "e"])
In [16]: frame.iloc[:,2] = np.nan

# Series with Series
In [17]: frame["a"].corr(frame["b"])
Out[17]: 0.013479040400098775

In [18]: frame["a"].corr(frame["b"], method="spearman")
Out[18]: -0.007289885159540637

# Pairwise correlation of DataFrame columns
In [19]: frame.corr()
Out[19]:
      a          b          c          d          e
a  1.000000  0.013479 -0.049269 -0.042239 -0.028525
b  0.013479  1.000000 -0.020433 -0.011139  0.005654
c -0.049269 -0.020433  1.000000  0.018587 -0.054269
d -0.042239 -0.011139  0.018587  1.000000 -0.017060
e -0.028525  0.005654 -0.054269 -0.017060  1.000000
```

Note that non-numeric columns will be automatically excluded from the correlation calculation.

Like cov, corr also supports the optional `min_periods` keyword:

```
In [20]: frame = pd.DataFrame(np.random.randn(20, 3), columns=["a", "b", "c"])

In [21]: frame.loc[frame.index[:5], "a"] = np.nan

In [22]: frame.loc[frame.index[5:10], "b"] = np.nan

In [23]: frame.corr()
Out[23]:
      a          b          c
a  1.000000 -0.121111  0.069544
b -0.121111  1.000000  0.051742
c  0.069544  0.051742  1.000000

In [24]: frame.corr(min_periods=12)
Out[24]:
      a          b          c
a  1.000000      NaN  0.069544
b      NaN  1.000000  0.051742
c  0.069544  0.051742  1.000000
```

The `method` argument can also be a callable for a generic correlation calculation. In this case, it should be a single function that produces a single value from two ndarray inputs. Suppose we wanted to compute the correlation based on histogram intersection:

```
# histogram intersection
In [25]: def histogram_intersection(a, b):
    ....:     return np.minimum(np.true_divide(a, a.sum()), np.true_divide(b, b.sum()))
    ↵sum()
    ....:

In [26]: frame.corr(method=histogram_intersection)
Out[26]:
      a          b          c
a  1.000000 -6.404882 -2.058431
b -6.404882  1.000000 -19.255743
c -2.058431 -19.255743  1.000000
```

A related method `corrwith()` is implemented on DataFrame to compute the correlation between like-labeled Series contained in different DataFrame objects.

```
In [27]: index = ["a", "b", "c", "d", "e"]

In [28]: columns = ["one", "two", "three", "four"]

In [29]: df1 = pd.DataFrame(np.random.randn(5, 4), index=index, columns=columns)

In [30]: df2 = pd.DataFrame(np.random.randn(4, 4), index=index[:4], columns=columns)

In [31]: df1.corrwith(df2)
Out[31]:
```

(continues on next page)

(continued from previous page)

```
one    -0.125501
two    -0.493244
three   0.344056
four    0.004183
dtype: float64
```

In [32]: df2.corrwith(df1, axis=1)

Out[32]:

```
a    -0.675817
b     0.458296
c     0.190809
d    -0.186275
e      NaN
dtype: float64
```

Data ranking

The `rank()` method produces a data ranking with ties being assigned the mean of the ranks (by default) for the group:

In [33]: s = pd.Series(np.random.randn(5), index=list("abcde"))

In [34]: s["d"] = s["b"] # so there's a tie

In [35]: s.rank()

Out[35]:

```
a     5.0
b     2.5
c     1.0
d     2.5
e     4.0
dtype: float64
```

`rank()` is also a DataFrame method and can rank either the rows (`axis=0`) or the columns (`axis=1`). `NaN` values are excluded from the ranking.

In [36]: df = pd.DataFrame(np.random.randn(10, 6))

In [37]: df[4] = df[2][:5] # some ties

In [38]: df

Out[38]:

	0	1	2	3	4	5
0	-0.904948	-1.163537	-1.457187	0.135463	-1.457187	0.294650
1	-0.976288	-0.244652	-0.748406	-0.999601	-0.748406	-0.800809
2	0.401965	1.460840	1.256057	1.308127	1.256057	0.876004
3	0.205954	0.369552	-0.669304	0.038378	-0.669304	1.140296
4	-0.477586	-0.730705	-1.129149	-0.601463	-1.129149	-0.211196
5	-1.092970	-0.689246	0.908114	0.204848		NaN 0.463347
6	0.376892	0.959292	0.095572	-0.593740		NaN -0.069180
7	-1.002601	1.957794	-0.120708	0.094214		NaN -1.467422
8	-0.547231	0.664402	-0.519424	-0.073254		NaN -1.263544

(continues on next page)

(continued from previous page)

```
9 -0.250277 -0.237428 -1.056443  0.419477      NaN  1.375064
```

In [39]: df.rank(1)

Out[39]:

	0	1	2	3	4	5
0	4.0	3.0	1.5	5.0	1.5	6.0
1	2.0	6.0	4.5	1.0	4.5	3.0
2	1.0	6.0	3.5	5.0	3.5	2.0
3	4.0	5.0	1.5	3.0	1.5	6.0
4	5.0	3.0	1.5	4.0	1.5	6.0
5	1.0	2.0	5.0	3.0	NaN	4.0
6	4.0	5.0	3.0	1.0	NaN	2.0
7	2.0	5.0	3.0	4.0	NaN	1.0
8	2.0	5.0	3.0	4.0	NaN	1.0
9	2.0	3.0	1.0	4.0	NaN	5.0

rank optionally takes a parameter ascending which by default is true; when false, data is reverse-ranked, with larger values assigned a smaller rank.

rank supports different tie-breaking methods, specified with the method parameter:

- average : average rank of tied group
- min : lowest rank in the group
- max : highest rank in the group
- first : ranks assigned in the order they appear in the array

Windowing functions

See [the window operations user guide](#) for an overview of windowing functions.

2.18 Group by: split-apply-combine

By “group by” we are referring to a process involving one or more of the following steps:

- **Splitting** the data into groups based on some criteria.
- **Applying** a function to each group independently.
- **Combining** the results into a data structure.

Out of these, the split step is the most straightforward. In fact, in many situations we may wish to split the data set into groups and do something with those groups. In the apply step, we might wish to do one of the following:

- **Aggregation:** compute a summary statistic (or statistics) for each group. Some examples:
 - Compute group sums or means.
 - Compute group sizes / counts.
- **Transformation:** perform some group-specific computations and return a like-indexed object. Some examples:
 - Standardize data (zscore) within a group.
 - Filling NAs within groups with a value derived from each group.

- **Filtration:** discard some groups, according to a group-wise computation that evaluates True or False. Some examples:
 - Discard data that belongs to groups with only a few members.
 - Filter out data based on the group sum or mean.
- Some combination of the above: GroupBy will examine the results of the apply step and try to return a sensibly combined result if it doesn't fit into either of the above two categories.

Since the set of object instance methods on pandas data structures are generally rich and expressive, we often simply want to invoke, say, a DataFrame function on each group. The name GroupBy should be quite familiar to those who have used a SQL-based tool (or `itertools`), in which you can write code like:

```
SELECT Column1, Column2, mean(Column3), sum(Column4)
FROM SomeTable
GROUP BY Column1, Column2
```

We aim to make operations like this natural and easy to express using pandas. We'll address each area of GroupBy functionality then provide some non-trivial examples / use cases.

See the [cookbook](#) for some advanced strategies.

2.18.1 Splitting an object into groups

pandas objects can be split on any of their axes. The abstract definition of grouping is to provide a mapping of labels to group names. To create a GroupBy object (more on what the GroupBy object is later), you may do the following:

```
In [1]: df = pd.DataFrame(
...:     [
...:         ("bird", "Falconiformes", 389.0),
...:         ("bird", "Psittaciformes", 24.0),
...:         ("mammal", "Carnivora", 80.2),
...:         ("mammal", "Primates", np.nan),
...:         ("mammal", "Carnivora", 58),
...:     ],
...:     index=["falcon", "parrot", "lion", "monkey", "leopard"],
...:     columns=("class", "order", "max_speed"),
...: )
...:

In [2]: df
Out[2]:
      class          order  max_speed
falcon    bird  Falconiformes     389.0
parrot    bird  Psittaciformes     24.0
lion     mammal        Carnivora     80.2
monkey    mammal        Primates      NaN
leopard   mammal        Carnivora     58.0

# default is axis=0
In [3]: grouped = df.groupby("class")

In [4]: grouped = df.groupby("order", axis="columns")

In [5]: grouped = df.groupby(["class", "order"])
```

The mapping can be specified many different ways:

- A Python function, to be called on each of the axis labels.
- A list or NumPy array of the same length as the selected axis.
- A dict or Series, providing a `label -> group name` mapping.
- For DataFrame objects, a string indicating either a column name or an index level name to be used to group.
- `df.groupby('A')` is just syntactic sugar for `df.groupby(df['A'])`.
- A list of any of the above things.

Collectively we refer to the grouping objects as the **keys**. For example, consider the following DataFrame:

Note: A string passed to `groupby` may refer to either a column or an index level. If a string matches both a column name and an index level name, a `ValueError` will be raised.

```
In [6]: df = pd.DataFrame(
...:     {
...:         "A": ["foo", "bar", "foo", "bar", "foo", "bar", "foo", "foo"],
...:         "B": ["one", "one", "two", "three", "two", "two", "one", "three"],
...:         "C": np.random.randn(8),
...:         "D": np.random.randn(8),
...:     }
...: )
...:
```

```
In [7]: df
Out[7]:
   A      B      C      D
0  foo    one  0.469112 -0.861849
1  bar    one -0.282863 -2.104569
2  foo    two -1.509059 -0.494929
3  bar  three -1.135632  1.071804
4  foo    two  1.212112  0.721555
5  bar    two -0.173215 -0.706771
6  foo    one  0.119209 -1.039575
7  foo  three -1.044236  0.271860
```

On a DataFrame, we obtain a GroupBy object by calling `groupby()`. We could naturally group by either the A or B columns, or both:

```
In [8]: grouped = df.groupby("A")
In [9]: grouped = df.groupby(["A", "B"])
```

If we also have a MultiIndex on columns A and B, we can group by all but the specified columns

```
In [10]: df2 = df.set_index(["A", "B"])
In [11]: grouped = df2.groupby(level=df2.index.names.difference(["B"]))
In [12]: grouped.sum()
Out[12]:
```

(continues on next page)

(continued from previous page)

	C	D
A		
bar	-1.591710	-1.739537
foo	-0.752861	-1.402938

These will split the DataFrame on its index (rows). We could also split by the columns:

```
In [13]: def get_letter_type(letter):
....:     if letter.lower() in 'aeiou':
....:         return 'vowel'
....:     else:
....:         return 'consonant'
....:

In [14]: grouped = df.groupby(get_letter_type, axis=1)
```

pandas `Index` objects support duplicate values. If a non-unique index is used as the group key in a groupby operation, all values for the same index value will be considered to be in one group and thus the output of aggregation functions will only contain unique index values:

```
In [15]: lst = [1, 2, 3, 1, 2, 3]

In [16]: s = pd.Series([1, 2, 3, 10, 20, 30], lst)

In [17]: grouped = s.groupby(level=0)

In [18]: grouped.first()
Out[18]:
1    1
2    2
3    3
dtype: int64

In [19]: grouped.last()
Out[19]:
1    10
2    20
3    30
dtype: int64

In [20]: grouped.sum()
Out[20]:
1    11
2    22
3    33
dtype: int64
```

Note that **no splitting occurs** until it's needed. Creating the GroupBy object only verifies that you've passed a valid mapping.

Note: Many kinds of complicated data manipulations can be expressed in terms of GroupBy operations (though can't be guaranteed to be the most efficient). You can get quite creative with the label mapping functions.

GroupBy sorting

By default the group keys are sorted during the groupby operation. You may however pass `sort=False` for potential speedups:

```
In [21]: df2 = pd.DataFrame({'X': ['B', 'B', 'A', 'A'], 'Y': [1, 2, 3, 4]})
```

```
In [22]: df2.groupby(['X']).sum()
```

```
Out[22]:
```

	Y
X	
A	7
B	3

```
In [23]: df2.groupby(['X'], sort=False).sum()
```

```
Out[23]:
```

	Y
X	
B	3
A	7

Note that `groupby` will preserve the order in which *observations* are sorted *within* each group. For example, the groups created by `groupby()` below are in the order they appeared in the original DataFrame:

```
In [24]: df3 = pd.DataFrame({'X': ['A', 'B', 'A', 'B'], 'Y': [1, 4, 3, 2]})
```

```
In [25]: df3.groupby(['X']).get_group('A')
```

```
Out[25]:
```

	X	Y
0	A	1
2	A	3

```
In [26]: df3.groupby(['X']).get_group('B')
```

```
Out[26]:
```

	X	Y
1	B	4
3	B	2

New in version 1.1.0.

GroupBy dropna

By default NA values are excluded from group keys during the `groupby` operation. However, in case you want to include NA values in group keys, you could pass `dropna=False` to achieve it.

```
In [27]: df_list = [[1, 2, 3], [1, None, 4], [2, 1, 3], [1, 2, 2]]
```

```
In [28]: df_dropna = pd.DataFrame(df_list, columns=['a', 'b', 'c'])
```

```
In [29]: df_dropna
```

```
Out[29]:
```

	a	b	c
0	1	2.0	3

(continues on next page)

(continued from previous page)

```
1 1   NaN  4
2 2   1.0  3
3 1   2.0  2
```

Default ``dropna`` is set to True, which will exclude NaNs in keys

In [30]: df_dropna.groupby(by=["b"], dropna=True).sum()

Out[30]:

```
      a   c
b
1.0  2   3
2.0  2   5
```

In order to allow NaN in keys, set ``dropna`` to False

In [31]: df_dropna.groupby(by=["b"], dropna=False).sum()

Out[31]:

```
      a   c
b
1.0  2   3
2.0  2   5
NaN  1   4
```

The default setting of `dropna` argument is `True` which means `NA` are not included in group keys.

GroupBy object attributes

The `groups` attribute is a dict whose keys are the computed unique groups and corresponding values being the axis labels belonging to each group. In the above example we have:

In [32]: df.groupby("A").groups

Out[32]: {'bar': [1, 3, 5], 'foo': [0, 2, 4, 6, 7]}

In [33]: df.groupby(get_letter_type, axis=1).groups

Out[33]: {'consonant': ['B', 'C', 'D'], 'vowel': ['A']}

Calling the standard Python `len` function on the GroupBy object just returns the length of the `groups` dict, so it is largely just a convenience:

In [34]: grouped = df.groupby(["A", "B"])

In [35]: grouped.groups

Out[35]: {('bar', 'one'): [1], ('bar', 'three'): [3], ('bar', 'two'): [5], ('foo', 'one'):
→: [0, 6], ('foo', 'three'): [7], ('foo', 'two'): [2, 4]}

In [36]: len(grouped)

Out[36]: 6

GroupBy will tab complete column names (and other attributes):

In [37]: df

Out[37]:

	height	weight	gender
2000-01-01	42.849980	157.500553	male

(continues on next page)

GroupBy with MultiIndex

With *hierarchically-indexed data*, it's quite natural to group by one of the levels of the hierarchy.

Let's create a Series with a two-level MultiIndex.

```
In [40]: arrays = [
....:     ["bar", "bar", "baz", "baz", "foo", "foo", "qux", "qux"],
....:     ["one", "two", "one", "two", "one", "two", "one", "two"],
....: ]
....:
```

```
In [41]: index = pd.MultiIndex.from_arrays(arrays, names=["first", "second"])
```

```
In [42]: s = pd.Series(np.random.randn(8), index=index)
```

In [43]: `s`

Out[43]:

```
first  second
bar    one      -0.919854
       two      -0.042379
baz    one      1.247642
       two      -0.009920
foo    one      0.290213
       two      0.495767
qux    one      0.362949
       two      1.548106
dtype: float64
```

We can then group by one of the levels in `s`.

```
In [44]: grouped = s.groupby(level=0)
```

```
In [45]: grouped.sum()
```

```
Out[45]:
```

```
first
bar    -0.962232
baz     1.237723
foo     0.785980
qux    1.911055
dtype: float64
```

If the MultiIndex has names specified, these can be passed instead of the level number:

```
In [46]: s.groupby(level="second").sum()
```

```
Out[46]:
```

```
second
one    0.980950
two    1.991575
dtype: float64
```

Grouping with multiple levels is supported.

```
In [47]: s
```

```
Out[47]:
```

```
first  second   third
bar    doo      one    -1.131345
                  two    -0.089329
baz    bee      one     0.337863
                  two    -0.945867
foo    bop      one    -0.932132
                  two     1.956030
qux    bop      one     0.017587
                  two    -0.016692
dtype: float64
```

```
In [48]: s.groupby(level=["first", "second"]).sum()
```

```
Out[48]:
```

```
first  second
bar    doo      -1.220674
baz    bee      -0.608004
foo    bop      1.023898
qux    bop      0.000895
dtype: float64
```

Index level names may be supplied as keys.

```
In [49]: s.groupby(["first", "second"]).sum()
```

```
Out[49]:
```

```
first  second
bar    doo      -1.220674
baz    bee      -0.608004
foo    bop      1.023898
```

(continues on next page)

(continued from previous page)

```
qux    bop      0.000895
dtype: float64
```

More on the `sum` function and aggregation later.

Grouping DataFrame with Index levels and columns

A DataFrame may be grouped by a combination of columns and index levels by specifying the column names as strings and the index levels as `pd.Grouper` objects.

```
In [50]: arrays = [
.....      ["bar", "bar", "baz", "baz", "foo", "foo", "qux", "qux"],
.....      ["one", "two", "one", "two", "one", "two", "one", "two"],
.....  ]
.....]

In [51]: index = pd.MultiIndex.from_arrays(arrays, names=["first", "second"])

In [52]: df = pd.DataFrame({"A": [1, 1, 1, 1, 2, 2, 3, 3], "B": np.arange(8)}, index=index)

In [53]: df
Out[53]:
          A   B
first second
bar   one     1  0
      two     1  1
baz   one     1  2
      two     1  3
foo   one     2  4
      two     2  5
qux   one     3  6
      two     3  7
```

The following example groups `df` by the second index level and the `A` column.

```
In [54]: df.groupby([pd.Grouper(level=1), "A"]).sum()
Out[54]:
          B
second A
one    1  2
      2  4
      3  6
two    1  4
      2  5
      3  7
```

Index levels may also be specified by name.

```
In [55]: df.groupby([pd.Grouper(level="second"), "A"]).sum()
Out[55]:
          B
```

(continues on next page)

(continued from previous page)

	second	A
one	1	2
	2	4
	3	6
two	1	4
	2	5
	3	7

Index level names may be specified as keys directly to groupby.

```
In [56]: df.groupby(["second", "A"]).sum()
```

```
Out[56]:
```

	B
second	A
one	1 2
	2 4
	3 6
two	1 4
	2 5
	3 7

DataFrame column selection in GroupBy

Once you have created the GroupBy object from a DataFrame, you might want to do something different for each of the columns. Thus, using [] similar to getting a column from a DataFrame, you can do:

```
In [57]: df = pd.DataFrame(
    ....:
    ....:     {
    ....:         "A": ["foo", "bar", "foo", "bar", "foo", "bar", "foo", "foo"],
    ....:         "B": ["one", "one", "two", "three", "two", "two", "one", "three"],
    ....:         "C": np.random.randn(8),
    ....:         "D": np.random.randn(8),
    ....:     }
    ....:
    ....: )
```

```
In [58]: df
```

```
Out[58]:
```

	A	B	C	D
0	foo	one	-0.575247	1.346061
1	bar	one	0.254161	1.511763
2	foo	two	-1.143704	1.627081
3	bar	three	0.215897	-0.990582
4	foo	two	1.193555	-0.441652
5	bar	two	-0.077118	1.211526
6	foo	one	-0.408530	0.268520
7	foo	three	-0.862495	0.024580

```
In [59]: grouped = df.groupby(["A"])
```

```
In [60]: grouped_C = grouped["C"]
```

(continues on next page)

(continued from previous page)

```
In [61]: grouped_D = grouped["D"]
```

This is mainly syntactic sugar for the alternative and much more verbose:

```
In [62]: df["C"].groupby(df["A"])
```

```
Out[62]: <pandas.core.groupby.generic.SeriesGroupBy object at 0x7f5534f9a2b0>
```

Additionally this method avoids recomputing the internal grouping information derived from the passed key.

2.18.2 Iterating through groups

With the GroupBy object in hand, iterating through the grouped data is very natural and functions similarly to `itertools.groupby()`:

```
In [63]: grouped = df.groupby('A')
```

```
In [64]: for name, group in grouped:
```

```
....:     print(name)
....:     print(group)
....:
```

```
bar
```

	A	B	C	D
1	bar	one	0.254161	1.511763
3	bar	three	0.215897	-0.990582
5	bar	two	-0.077118	1.211526
	foo			
0	foo	one	-0.575247	1.346061
2	foo	two	-1.143704	1.627081
4	foo	two	1.193555	-0.441652
6	foo	one	-0.408530	0.268520
7	foo	three	-0.862495	0.024580

In the case of grouping by multiple keys, the group name will be a tuple:

```
In [65]: for name, group in df.groupby(['A', 'B']):
```

```
....:     print(name)
....:     print(group)
....:
```

```
('bar', 'one')
```

	A	B	C	D
1	bar	one	0.254161	1.511763

```
('bar', 'three')
```

	A	B	C	D
3	bar	three	0.215897	-0.990582

```
('bar', 'two')
```

	A	B	C	D
5	bar	two	-0.077118	1.211526

```
('foo', 'one')
```

	A	B	C	D
0	foo	one	-0.575247	1.346061

(continues on next page)

(continued from previous page)

```

6  foo  one -0.408530  0.268520
('foo', 'three')
      A      B      C      D
7  foo  three -0.862495  0.02458
('foo', 'two')
      A      B      C      D
2  foo  two -1.143704  1.627081
4  foo  two  1.193555 -0.441652

```

See [Iterating through groups](#).

2.18.3 Selecting a group

A single group can be selected using `get_group()`:

```

In [66]: grouped.get_group("bar")
Out[66]:
      A      B      C      D
1  bar  one  0.254161  1.511763
3  bar  three  0.215897 -0.990582
5  bar  two -0.077118  1.211526

```

Or for an object grouped on multiple columns:

```

In [67]: df.groupby(["A", "B"]).get_group(("bar", "one"))
Out[67]:
      A      B      C      D
1  bar  one  0.254161  1.511763

```

2.18.4 Aggregation

Once the GroupBy object has been created, several methods are available to perform a computation on the grouped data. These operations are similar to the [aggregating API](#), [window API](#), and [resample API](#).

An obvious one is aggregation via the `aggregate()` or equivalently `agg()` method:

```

In [68]: grouped = df.groupby("A")

In [69]: grouped.aggregate(np.sum)
Out[69]:
      C      D
A
bar  0.392940  1.732707
foo -1.796421  2.824590

In [70]: grouped = df.groupby(["A", "B"])

In [71]: grouped.aggregate(np.sum)
Out[71]:
      C      D
A   B

```

(continues on next page)

(continued from previous page)

bar	one	0.254161	1.511763
	three	0.215897	-0.990582
	two	-0.077118	1.211526
foo	one	-0.983776	1.614581
	three	-0.862495	0.024580
	two	0.049851	1.185429

As you can see, the result of the aggregation will have the group names as the new index along the grouped axis. In the case of multiple keys, the result is a `MultiIndex` by default, though this can be changed by using the `as_index=False` option:

In [72]: `grouped = df.groupby(["A", "B"], as_index=False)`

In [73]: `grouped.aggregate(np.sum)`

Out[73]:

	A	B	C	D
0	bar	one	0.254161	1.511763
1	bar	three	0.215897	-0.990582
2	bar	two	-0.077118	1.211526
3	foo	one	-0.983776	1.614581
4	foo	three	-0.862495	0.024580
5	foo	two	0.049851	1.185429

In [74]: `df.groupby("A", as_index=False).sum()`

Out[74]:

	A	C	D
0	bar	0.392940	1.732707
1	foo	-1.796421	2.824590

Note that you could use the `reset_index` DataFrame function to achieve the same result as the column names are stored in the resulting `MultiIndex`:

In [75]: `df.groupby(["A", "B"]).sum().reset_index()`

Out[75]:

	A	B	C	D
0	bar	one	0.254161	1.511763
1	bar	three	0.215897	-0.990582
2	bar	two	-0.077118	1.211526
3	foo	one	-0.983776	1.614581
4	foo	three	-0.862495	0.024580
5	foo	two	0.049851	1.185429

Another simple aggregation example is to compute the size of each group. This is included in GroupBy as the `size` method. It returns a Series whose index are the group names and whose values are the sizes of each group.

In [76]: `grouped.size()`

Out[76]:

	A	B	size
0	bar	one	1
1	bar	three	1
2	bar	two	1
3	foo	one	2
4	foo	three	1
5	foo	two	2

```
In [77]: grouped.describe()
Out[77]:
          C                               ...                               D
count      mean      std      min      25%      50%  ...      std      min
25%      50%      75%      max
0    1.0  0.254161      NaN  0.254161  0.254161  0.254161  ...      NaN  1.511763  1.
    511763  1.511763  1.511763  1.511763
1    1.0  0.215897      NaN  0.215897  0.215897  0.215897  ...      NaN -0.990582 -0.
    990582 -0.990582 -0.990582 -0.990582
2    1.0 -0.077118      NaN -0.077118 -0.077118 -0.077118  ...      NaN  1.211526  1.
    211526  1.211526  1.211526  1.211526
3    2.0 -0.491888  0.117887 -0.575247 -0.533567 -0.491888  ...  0.761937  0.268520  0.
    537905  0.807291  1.076676  1.346061
4    1.0 -0.862495      NaN -0.862495 -0.862495 -0.862495  ...      NaN  0.024580  0.
    024580  0.024580  0.024580
5    2.0  0.024925  1.652692 -1.143704 -0.559389  0.024925  ...  1.462816 -0.441652  0.
    075531  0.592714  1.109898  1.627081

[6 rows x 16 columns]
```

Another aggregation example is to compute the number of unique values of each group. This is similar to the `value_counts` function, except that it only counts unique values.

```
In [78]: ll = [['foo', 1], ['foo', 2], ['foo', 2], ['bar', 1], ['bar', 1]]
In [79]: df4 = pd.DataFrame(ll, columns=["A", "B"])
In [80]: df4
Out[80]:
      A   B
0  foo   1
1  foo   2
2  foo   2
3  bar   1
4  bar   1

In [81]: df4.groupby("A")["B"].nunique()
Out[81]:
A
bar    1
foo    2
Name: B, dtype: int64
```

Note: Aggregation functions **will not** return the groups that you are aggregating over if they are named `columns`, when `as_index=True`, the default. The grouped columns will be the `indices` of the returned object.

Passing `as_index=False` **will** return the groups that you are aggregating over, if they are named `columns`.

Aggregating functions are the ones that reduce the dimension of the returned objects. Some common aggregating functions are tabulated below:

Function	Description
mean()	Compute mean of groups
sum()	Compute sum of group values
size()	Compute group sizes
count()	Compute count of group
std()	Standard deviation of groups
var()	Compute variance of groups
sem()	Standard error of the mean of groups
describe()	Generates descriptive statistics
first()	Compute first of group values
last()	Compute last of group values
nth()	Take nth value, or a subset if n is a list
min()	Compute min of group values
max()	Compute max of group values

The aggregating functions above will exclude NA values. Any function which reduces a `Series` to a scalar value is an aggregation function and will work, a trivial example is `df.groupby('A').agg(lambda ser: 1)`. Note that `nth()` can act as a reducer *or* a filter, see [here](#).

Applying multiple functions at once

With grouped `Series` you can also pass a list or dict of functions to do aggregation with, outputting a DataFrame:

```
In [82]: grouped = df.groupby("A")
In [83]: grouped["C"].agg([np.sum, np.mean, np.std])
Out[83]:
          sum      mean      std
A
bar  0.392940  0.130980  0.181231
foo -1.796421 -0.359284  0.912265
```

On a grouped DataFrame, you can pass a list of functions to apply to each column, which produces an aggregated result with a hierarchical index:

```
In [84]: grouped[["C", "D"]].agg([np.sum, np.mean, np.std])
Out[84]:
              C                               D
          sum      mean      std      sum      mean      std
A
bar  0.392940  0.130980  0.181231  1.732707  0.577569  1.366330
foo -1.796421 -0.359284  0.912265  2.824590  0.564918  0.884785
```

The resulting aggregations are named for the functions themselves. If you need to rename, then you can add in a chained operation for a `Series` like this:

```
In [85]: (
    ....:     grouped["C"]
    ....:     .agg([np.sum, np.mean, np.std])
    ....:     .rename(columns={"sum": "foo", "mean": "bar", "std": "baz"})
    ....: )
    ....:
```

(continues on next page)

(continued from previous page)

Out[85]:

	foo	bar	baz
A			
bar	0.392940	0.130980	0.181231
foo	-1.796421	-0.359284	0.912265

For a grouped DataFrame, you can rename in a similar manner:

In [86]:

```
....:     grouped[["C", "D"]].agg([np.sum, np.mean, np.std]).rename(
....:         columns={"sum": "foo", "mean": "bar", "std": "baz"})
....:
....:
```

Out[86]:

	C			D		
	foo	bar	baz	foo	bar	baz
A						
bar	0.392940	0.130980	0.181231	1.732707	0.577569	1.366330
foo	-1.796421	-0.359284	0.912265	2.824590	0.564918	0.884785

Note: In general, the output column names should be unique. You can't apply the same function (or two functions with the same name) to the same column.

In [87]: grouped["C"].agg(["sum", "sum"])**Out[87]:**

	sum	sum
A		
bar	0.392940	0.392940
foo	-1.796421	-1.796421

pandas *does* allow you to provide multiple lambdas. In this case, pandas will mangle the name of the (nameless) lambda functions, appending _<i> to each subsequent lambda.

In [88]: grouped["C"].agg([lambda x: x.max() - x.min(), lambda x: x.median() - x.mean()])**Out[88]:**

	<lambda_0>	<lambda_1>
A		
bar	0.331279	0.084917
foo	2.337259	-0.215962

Named aggregation

New in version 0.25.0.

To support column-specific aggregation *with control over the output column names*, pandas accepts the special syntax in `GroupBy.agg()`, known as “named aggregation”, where

- The keywords are the *output* column names
- The values are tuples whose first element is the column to select and the second element is the aggregation to apply to that column. pandas provides the `pandas.NamedAgg` namedtuple with the fields `['column', 'aggfunc']` to make it clearer what the arguments are. As usual, the aggregation can be a callable or a string alias.

```
In [89]: animals = pd.DataFrame(
....:     {
....:         "kind": ["cat", "dog", "cat", "dog"],
....:         "height": [9.1, 6.0, 9.5, 34.0],
....:         "weight": [7.9, 7.5, 9.9, 198.0],
....:     }
....: )
....:
```

```
In [90]: animals
Out[90]:
   kind  height  weight
0  cat      9.1    7.9
1  dog      6.0    7.5
2  cat      9.5    9.9
3  dog     34.0   198.0
```

```
In [91]: animals.groupby("kind").agg(
....:     min_height=pd.NamedAgg(column="height", aggfunc="min"),
....:     max_height=pd.NamedAgg(column="height", aggfunc="max"),
....:     average_weight=pd.NamedAgg(column="weight", aggfunc=np.mean),
....: )
....:
```

```
Out[91]:
           min_height  max_height  average_weight
kind
cat              9.1          9.5            8.90
dog              6.0         34.0           102.75
```

`pandas.NamedAgg` is just a namedtuple. Plain tuples are allowed as well.

```
In [92]: animals.groupby("kind").agg(
....:     min_height=("height", "min"),
....:     max_height=("height", "max"),
....:     average_weight=("weight", np.mean),
....: )
....:
```

```
Out[92]:
           min_height  max_height  average_weight
kind
cat              9.1          9.5            8.90
dog              6.0         34.0           102.75
```

If your desired output column names are not valid Python keywords, construct a dictionary and unpack the keyword arguments

```
In [93]: animals.groupby("kind").agg(  
.....:     **{  
.....:         "total weight": pd.NamedAgg(column="weight", aggfunc=sum)  
.....:     }  
.....:  
Out[93]:  
      total weight  
kind  
cat           17.8  
dog          205.5
```

Additional keyword arguments are not passed through to the aggregation functions. Only pairs of (column, aggfunc) should be passed as `**kwargs`. If your aggregation functions requires additional arguments, partially apply them with `functools.partial()`.

Note: For Python 3.5 and earlier, the order of `**kwargs` in a functions was not preserved. This means that the output column ordering would not be consistent. To ensure consistent ordering, the keys (and so output columns) will always be sorted for Python 3.5.

Named aggregation is also valid for Series groupby aggregations. In this case there's no column selection, so the values are just the functions.

```
In [94]: animals.groupby("kind").height.agg(  
.....:     min_height="min",  
.....:     max_height="max",  
.....:  
.....:  
Out[94]:  
      min_height  max_height  
kind  
cat           9.1           9.5  
dog          6.0          34.0
```

Applying different functions to DataFrame columns

By passing a dict to `aggregate` you can apply a different aggregation to the columns of a DataFrame:

```
In [95]: grouped.agg({"C": np.sum, "D": lambda x: np.std(x, ddof=1)})  
Out[95]:  
          C          D  
A  
bar  0.392940  1.366330  
foo -1.796421  0.884785
```

The function names can also be strings. In order for a string to be valid it must be either implemented on GroupBy or available via `dispatching`:

```
In [96]: grouped.agg({"C": "sum", "D": "std"})
Out[96]:
          C          D
A
bar  0.392940  1.366330
foo -1.796421  0.884785
```

Cython-optimized aggregation functions

Some common aggregations, currently only `sum`, `mean`, `std`, and `sem`, have optimized Cython implementations:

```
In [97]: df.groupby("A").sum()
Out[97]:
          C          D
A
bar  0.392940  1.732707
foo -1.796421  2.824590

In [98]: df.groupby(["A", "B"]).mean()
Out[98]:
          C          D
A   B
bar one    0.254161  1.511763
     three   0.215897 -0.990582
     two    -0.077118  1.211526
foo one    -0.491888  0.807291
     three   -0.862495  0.024580
     two     0.024925  0.592714
```

Of course `sum` and `mean` are implemented on pandas objects, so the above code would work even without the special versions via dispatching (see below).

Aggregations with User-Defined Functions

Users can also provide their own functions for custom aggregations. When aggregating with a User-Defined Function (UDF), the UDF should not mutate the provided Series, see [Mutating with User Defined Function \(UDF\) methods](#) for more information.

```
In [99]: animals.groupby("kind") [["height"]].agg(lambda x: set(x))
Out[99]:
           height
kind
cat      {9.1, 9.5}
dog      {34.0, 6.0}
```

The resulting dtype will reflect that of the aggregating function. If the results from different groups have different dtypes, then a common dtype will be determined in the same way as DataFrame construction.

```
In [100]: animals.groupby("kind") [["height"]].agg(lambda x: x.astype(int).sum())
Out[100]:
           height
```

(continues on next page)

(continued from previous page)

kind
cat
dog

2.18.5 Transformation

The `transform` method returns an object that is indexed the same (same size) as the one being grouped. The transform function must:

- Return a result that is either the same size as the group chunk or broadcastable to the size of the group chunk (e.g., a scalar, `grouped.transform(lambda x: x.iloc[-1])`).
- Operate column-by-column on the group chunk. The transform is applied to the first group chunk using `chunk.apply`.
- Not perform in-place operations on the group chunk. Group chunks should be treated as immutable, and changes to a group chunk may produce unexpected results. For example, when using `fillna`, `inplace` must be `False` (`grouped.transform(lambda x: x.fillna(inplace=False))`).
- (Optionally) operates on the entire group chunk. If this is supported, a fast path is used starting from the *second* chunk.

Similar to [Aggregations with User-Defined Functions](#), the resulting dtype will reflect that of the transformation function. If the results from different groups have different dtypes, then a common dtype will be determined in the same way as `DataFrame` construction.

Suppose we wished to standardize the data within each group:

```
In [101]: index = pd.date_range("10/1/1999", periods=1100)

In [102]: ts = pd.Series(np.random.normal(0.5, 2, 1100), index)

In [103]: ts = ts.rolling(window=100, min_periods=100).mean().dropna()

In [104]: ts.head()
Out[104]:
2000-01-08    0.779333
2000-01-09    0.778852
2000-01-10    0.786476
2000-01-11    0.782797
2000-01-12    0.798110
Freq: D, dtype: float64

In [105]: ts.tail()
Out[105]:
2002-09-30    0.660294
2002-10-01    0.631095
2002-10-02    0.673601
2002-10-03    0.709213
2002-10-04    0.719369
Freq: D, dtype: float64

In [106]: transformed = ts.groupby(lambda x: x.year).transform(
.....:     lambda x: (x - x.mean()) / x.std()
```

(continues on next page)

(continued from previous page)

```
.....: )
.....:
```

We would expect the result to now have mean 0 and standard deviation 1 within each group, which we can easily check:

```
# Original Data
In [107]: grouped = ts.groupby(lambda x: x.year)

In [108]: grouped.mean()
Out[108]:
2000    0.442441
2001    0.526246
2002    0.459365
dtype: float64

In [109]: grouped.std()
Out[109]:
2000    0.131752
2001    0.210945
2002    0.128753
dtype: float64

# Transformed Data
In [110]: grouped_trans = transformed.groupby(lambda x: x.year)

In [111]: grouped_trans.mean()
Out[111]:
2000    1.193722e-15
2001    1.945476e-15
2002    1.272949e-15
dtype: float64

In [112]: grouped_trans.std()
Out[112]:
2000    1.0
2001    1.0
2002    1.0
dtype: float64
```

We can also visually compare the original and transformed data sets.

```
In [113]: compare = pd.DataFrame({"Original": ts, "Transformed": transformed})

In [114]: compare.plot()
Out[114]: <AxesSubplot:>
```

Transformation functions that have lower dimension outputs are broadcast to match the shape of the input array.

```
In [115]: ts.groupby(lambda x: x.year).transform(lambda x: x.max() - x.min())
```

Out[115]:

2000-01-08	0.623893
2000-01-09	0.623893
2000-01-10	0.623893
2000-01-11	0.623893
2000-01-12	0.623893
...	
2002-09-30	0.558275
2002-10-01	0.558275
2002-10-02	0.558275
2002-10-03	0.558275
2002-10-04	0.558275

Freq: D, Length: 1001, dtype: float64

Alternatively, the built-in methods could be used to produce the same outputs.

```
In [116]: max = ts.groupby(lambda x: x.year).transform("max")
```

```
In [117]: min = ts.groupby(lambda x: x.year).transform("min")
```

```
In [118]: max - min
```

(continues on next page)

(continued from previous page)

Out[118]:

```

2000-01-08    0.623893
2000-01-09    0.623893
2000-01-10    0.623893
2000-01-11    0.623893
2000-01-12    0.623893
...
2002-09-30    0.558275
2002-10-01    0.558275
2002-10-02    0.558275
2002-10-03    0.558275
2002-10-04    0.558275
Freq: D, Length: 1001, dtype: float64

```

Another common data transform is to replace missing data with the group mean.

In [119]: data_df**Out[119]:**

	A	B	C
0	1.539708	-1.166480	0.533026
1	1.302092	-0.505754	NaN
2	-0.371983	1.104803	-0.651520
3	-1.309622	1.118697	-1.161657
4	-1.924296	0.396437	0.812436

997	-0.394469	-0.642343	0.011374
998	-1.174126	1.857148	NaN
999	0.234564	0.517098	0.393534

[1000 rows x 3 columns]

In [120]: countries = np.array(["US", "UK", "GR", "JP"])**In [121]:** key = countries[np.random.randint(0, 4, 1000)]**In [122]:** grouped = data_df.groupby(key)

Non-NA count in each group

In [123]: grouped.count()**Out[123]:**

	A	B	C
GR	209	217	189
JP	240	255	217
UK	216	231	193
US	239	250	217

In [124]: transformed = grouped.transform(lambda x: x.fillna(x.mean()))

We can verify that the group means have not changed in the transformed data and that the transformed data contains no NAs.

```
In [125]: grouped_trans = transformed.groupby(key)
```

```
In [126]: grouped.mean() # original group means
```

```
Out[126]:
```

	A	B	C
GR	-0.098371	-0.015420	0.068053

JP	0.069025	0.023100	-0.077324
UK	0.034069	-0.052580	-0.116525
US	0.058664	-0.020399	0.028603

```
In [128]: grouped.count() # original has some missing data points
```

```
Out[128]:
```

	A	B	C
GR	209	217	189
JP	240	255	217
UK	216	231	193
US	239	250	217

```
In [129]: grouped_trans.count() # counts after transformation
```

```
Out[129]:
```

	A	B	C
GR	228	228	228
JP	267	267	267
UK	247	247	247
US	258	258	258

```
In [130]: grouped_trans.size() # Verify non-NA count equals group size
```

```
Out[130]:
```

GR	228
JP	267
UK	247
US	258

```
dtype: int64
```

Note: Some functions will automatically transform the input when applied to a GroupBy object, but returning an object of the same shape as the original. Passing `as_index=False` will not affect these transformation methods.

For example: `fillna`, `ffill`, `bfill`, `shift..`

```
In [131]: grouped.ffill()
```

```
Out[131]:
```

	A	B	C
0	1.539708	-1.166480	0.533026
1	1.302092	-0.505754	0.533026

(continues on next page)

(continued from previous page)

```

2 -0.371983  1.104803 -0.651520
3 -1.309622  1.118697 -1.161657
4 -1.924296  0.396437  0.812436
...
995 -0.093110  0.683847 -0.774753
996 -0.185043  1.438572 -0.774753
997 -0.394469 -0.642343  0.011374
998 -1.174126  1.857148 -0.774753
999  0.234564  0.517098  0.393534

[1000 rows x 3 columns]

```

Window and resample operations

It is possible to use `resample()`, `expanding()` and `rolling()` as methods on groupbys.

The example below will apply the `rolling()` method on the samples of the column B based on the groups of column A.

```
In [132]: df_re = pd.DataFrame({"A": [1] * 10 + [5] * 10, "B": np.arange(20)})
```

```
In [133]: df_re
```

```
Out[133]:
```

	A	B
0	1	0
1	1	1
2	1	2
3	1	3
4	1	4
...
15	5	15
16	5	16
17	5	17
18	5	18
19	5	19

```
[20 rows x 2 columns]
```

```
In [134]: df_re.groupby("A").rolling(4).B.mean()
```

```
Out[134]:
```

	A	B
1	0	NaN
	1	NaN
	2	NaN
	3	1.5
	4	2.5
...		...
5	15	13.5
	16	14.5
	17	15.5

(continues on next page)

(continued from previous page)

```
18    16.5
19    17.5
Name: B, Length: 20, dtype: float64
```

The `expanding()` method will accumulate a given operation (`sum()` in the example) for all the members of each particular group.

In [135]: `df_re.groupby("A").expanding().sum()`

Out[135]:

```
B
A
1 0    0.0
1   1.0
2   3.0
3   6.0
4  10.0
...
5 15  75.0
16  91.0
17 108.0
18 126.0
19 145.0
```

```
[20 rows x 1 columns]
```

Suppose you want to use the `resample()` method to get a daily frequency in each group of your dataframe and wish to complete the missing values with the `ffill()` method.

In [136]: `df_re = pd.DataFrame(
...: {
...: "date": pd.date_range(start="2016-01-01", periods=4, freq="W"),
...: "group": [1, 1, 2, 2],
...: "val": [5, 6, 7, 8],
...: }
...:).set_index("date")`

In [137]: `df_re`

Out[137]:

	group	val
date		
2016-01-03	1	5
2016-01-10	1	6
2016-01-17	2	7
2016-01-24	2	8

In [138]: `df_re.groupby("group").resample("1D").ffill()`

Out[138]:

	group	val
group date		
1 2016-01-03	1	5
2016-01-04	1	5

(continues on next page)

(continued from previous page)

	2016-01-05	1	5
	2016-01-06	1	5
	2016-01-07	1	5
...
2	2016-01-20	2	7
	2016-01-21	2	7
	2016-01-22	2	7
	2016-01-23	2	7
	2016-01-24	2	8

[16 rows x 2 columns]

2.18.6 Filtration

The `filter` method returns a subset of the original object. Suppose we want to take only elements that belong to groups with a group sum greater than 2.

```
In [139]: sf = pd.Series([1, 1, 2, 3, 3, 3])
```

```
In [140]: sf.groupby(sf).filter(lambda x: x.sum() > 2)
```

Out[140]:

3	3
4	3
5	3

dtype: int64

The argument of `filter` must be a function that, applied to the group as a whole, returns True or False.

Another useful operation is filtering out elements that belong to groups with only a couple members.

```
In [141]: dff = pd.DataFrame({"A": np.arange(8), "B": list("aabbbbcc")})
```

```
In [142]: dff.groupby("B").filter(lambda x: len(x) > 2)
```

Out[142]:

	A	B
2	2	b
3	3	b
4	4	b
5	5	b

Alternatively, instead of dropping the offending groups, we can return a like-indexed objects where the groups that do not pass the filter are filled with NaNs.

```
In [143]: dff.groupby("B").filter(lambda x: len(x) > 2, dropna=False)
```

Out[143]:

	A	B
0	NaN	NaN
1	NaN	NaN
2	2.0	b
3	3.0	b
4	4.0	b
5	5.0	b

(continues on next page)

(continued from previous page)

```
6   NaN   NaN
7   NaN   NaN
```

For DataFrames with multiple columns, filters should explicitly specify a column as the filter criterion.

```
In [144]: dff["C"] = np.arange(8)
```

```
In [145]: dff.groupby("B").filter(lambda x: len(x["C"]) > 2)
```

```
Out[145]:
```

	A	B	C
2	2	b	2
3	3	b	3
4	4	b	4
5	5	b	5

Note: Some functions when applied to a groupby object will act as a `filter` on the input, returning a reduced shape of the original (and potentially eliminating groups), but with the index unchanged. Passing `as_index=False` will not affect these transformation methods.

For example: `head`, `tail`.

```
In [146]: dff.groupby("B").head(2)
```

```
Out[146]:
```

	A	B	C
0	0	a	0
1	1	a	1
2	2	b	2
3	3	b	3
6	6	c	6
7	7	c	7

2.18.7 Dispatching to instance methods

When doing an aggregation or transformation, you might just want to call an instance method on each data group. This is pretty easy to do by passing lambda functions:

```
In [147]: grouped = df.groupby("A")
```

```
In [148]: grouped.agg(lambda x: x.std())
```

```
Out[148]:
```

	C	D
A		
bar	0.181231	1.366330
foo	0.912265	0.884785

But, it's rather verbose and can be untidy if you need to pass additional arguments. Using a bit of metaprogramming cleverness, GroupBy now has the ability to "dispatch" method calls to the groups:

```
In [149]: grouped.std()
```

```
Out[149]:
```

(continues on next page)

(continued from previous page)

	C	D
A		
bar	0.181231	1.366330
foo	0.912265	0.884785

What is actually happening here is that a function wrapper is being generated. When invoked, it takes any passed arguments and invokes the function with any arguments on each group (in the above example, the `std` function). The results are then combined together much in the style of `agg` and `transform` (it actually uses `apply` to infer the gluing, documented next). This enables some operations to be carried out rather succinctly:

```
In [150]: tsdf = pd.DataFrame(
.....:     np.random.randn(1000, 3),
.....:     index=pd.date_range("1/1/2000", periods=1000),
.....:     columns=["A", "B", "C"],
.....: )
.....:

In [151]: tsdf.iloc[::2] = np.nan

In [152]: grouped = tsdf.groupby(lambda x: x.year)

In [153]: grouped.fillna(method="pad")
Out[153]:
          A         B         C
2000-01-01    NaN      NaN      NaN
2000-01-02 -0.353501 -0.080957 -0.876864
2000-01-03 -0.353501 -0.080957 -0.876864
2000-01-04  0.050976  0.044273 -0.559849
2000-01-05  0.050976  0.044273 -0.559849
...
...
2002-09-22  0.005011  0.053897 -1.026922
2002-09-23  0.005011  0.053897 -1.026922
2002-09-24 -0.456542 -1.849051  1.559856
2002-09-25 -0.456542 -1.849051  1.559856
2002-09-26  1.123162  0.354660  1.128135

[1000 rows x 3 columns]
```

In this example, we chopped the collection of time series into yearly chunks then independently called `fillna` on the groups.

The `nlargest` and `nsmallest` methods work on Series style groupbys:

```
In [154]: s = pd.Series([9, 8, 7, 5, 19, 1, 4.2, 3.3])

In [155]: g = pd.Series(list("abababab"))

In [156]: gb = s.groupby(g)

In [157]: gb.nlargest(3)
Out[157]:
a    4    19.0
     0    9.0
```

(continues on next page)

(continued from previous page)

```
2      7.0
b  1      8.0
     3      5.0
     7      3.3
dtype: float64
```

In [158]: `gb.nsmallest(3)`

Out[158]:

```
a  6      4.2
   2      7.0
   0      9.0
b  5      1.0
   7      3.3
   3      5.0
dtype: float64
```

2.18.8 Flexible apply

Some operations on the grouped data might not fit into either the aggregate or transform categories. Or, you may simply want GroupBy to infer how to combine the results. For these, use the `apply` function, which can be substituted for both `aggregate` and `transform` in many standard use cases. However, `apply` can handle some exceptional use cases, for example:

In [159]: `df`

Out[159]:

```
       A         B         C         D
0  foo    one -0.575247  1.346061
1  bar    one  0.254161  1.511763
2  foo    two -1.143704  1.627081
3  bar  three  0.215897 -0.990582
4  foo    two  1.193555 -0.441652
5  bar    two -0.077118  1.211526
6  foo    one -0.408530  0.268520
7  foo  three -0.862495  0.024580
```

In [160]: `grouped = df.groupby("A")`

could also just call `.describe()`

In [161]: `grouped["C"].apply(lambda x: x.describe())`

Out[161]:

```
A
bar  count    3.000000
      mean    0.130980
      std     0.181231
      min    -0.077118
      25%    0.069390
      ...
foo  min     -1.143704
      25%    -0.862495
      50%    -0.575247
      75%    -0.408530
```

(continues on next page)

(continued from previous page)

```
max      1.193555
Name: C, Length: 16, dtype: float64
```

The dimension of the returned result can also change:

```
In [162]: grouped = df.groupby('A')['C']

In [163]: def f(group):
.....:     return pd.DataFrame({'original': group,
.....:                           'demeaned': group - group.mean()})
.....:

In [164]: grouped.apply(f)
Out[164]:
   original  demeaned
0 -0.575247 -0.215962
1  0.254161  0.123181
2 -1.143704 -0.784420
3  0.215897  0.084917
4  1.193555  1.552839
5 -0.077118 -0.208098
6 -0.408530 -0.049245
7 -0.862495 -0.503211
```

`apply` on a Series can operate on a returned value from the applied function, that is itself a series, and possibly upcast the result to a DataFrame:

```
In [165]: def f(x):
.....:     return pd.Series([x, x ** 2], index=["x", "x^2"])
.....:

In [166]: s = pd.Series(np.random.rand(5))

In [167]: s
Out[167]:
0    0.321438
1    0.493496
2    0.139505
3    0.910103
4    0.194158
dtype: float64

In [168]: s.apply(f)
Out[168]:
          x      x^2
0  0.321438  0.103323
1  0.493496  0.243538
2  0.139505  0.019462
3  0.910103  0.828287
4  0.194158  0.037697
```

Note: `apply` can act as a reducer, transformer, or filter function, depending on exactly what is passed to it. So

depending on the path taken, and exactly what you are grouping. Thus the grouped columns(s) may be included in the output as well as set the indices.

Similar to [Aggregations with User-Defined Functions](#), the resulting dtype will reflect that of the apply function. If the results from different groups have different dtypes, then a common dtype will be determined in the same way as DataFrame construction.

2.18.9 Numba Accelerated Routines

New in version 1.1.

If Numba is installed as an optional dependency, the transform and aggregate methods support engine='numba' and engine_kwds arguments. See [enhancing performance with Numba](#) for general usage of the arguments and performance considerations.

The function signature must start with values, index exactly as the data belonging to each group will be passed into values, and the group index will be passed into index.

Warning: When using engine='numba', there will be no “fall back” behavior internally. The group data and group index will be passed as NumPy arrays to the JITed user defined function, and no alternative execution attempts will be tried.

2.18.10 Other useful features

Automatic exclusion of “nuisance” columns

Again consider the example DataFrame we've been looking at:

```
In [169]: df
Out[169]:
      A          B          C          D
0   foo     one -0.575247  1.346061
1   bar     one  0.254161  1.511763
2   foo     two -1.143704  1.627081
3   bar    three  0.215897 -0.990582
4   foo     two  1.193555 -0.441652
5   bar     two -0.077118  1.211526
6   foo     one -0.408530  0.268520
7   foo    three -0.862495  0.024580
```

Suppose we wish to compute the standard deviation grouped by the A column. There is a slight problem, namely that we don't care about the data in column B. We refer to this as a “nuisance” column. If the passed aggregation function can't be applied to some columns, the troublesome columns will be (silently) dropped. Thus, this does not pose any problems:

```
In [170]: df.groupby("A").std()
Out[170]:
      C          D
A
bar  0.181231  1.366330
foo  0.912265  0.884785
```

Note that `df.groupby('A').colname.std()` is more efficient than `df.groupby('A').std().colname`, so if the result of an aggregation function is only interesting over one column (here `colname`), it may be filtered *before* applying the aggregation function.

Note: Any object column, also if it contains numerical values such as `Decimal` objects, is considered as a “nuisance” columns. They are excluded from aggregate functions automatically in `groupby`.

If you do wish to include decimal or object columns in an aggregation with other non-nuisance data types, you must do so explicitly.

```
In [171]: from decimal import Decimal
```

```
In [172]: df_dec = pd.DataFrame(
.....:     {
.....:         "id": [1, 2, 1, 2],
.....:         "int_column": [1, 2, 3, 4],
.....:         "dec_column": [
.....:             Decimal("0.50"),
.....:             Decimal("0.15"),
.....:             Decimal("0.25"),
.....:             Decimal("0.40"),
.....:         ],
.....:     }
.....: )
```

Decimal columns can be sum'd explicitly by themselves...

```
In [173]: df_dec.groupby(["id"])[[ "dec_column"]].sum()
```

```
Out[173]:
      dec_column
id
1        0.75
2        0.55
```

...but cannot be combined with standard data types or they will be excluded

```
In [174]: df_dec.groupby(["id"])[[ "int_column", "dec_column"]].sum()
```

```
Out[174]:
      int_column
id
1        4
2        6
```

Use `.agg` function to aggregate over standard and “nuisance” data types

at the same time

```
In [175]: df_dec.groupby(["id"]).agg({"int_column": "sum", "dec_column": "sum"})
```

```
Out[175]:
      int_column  dec_column
id
1            4        0.75
2            6        0.55
```

Handling of (un)observed Categorical values

When using a Categorical grouper (as a single grouper, or as part of multiple groupers), the observed keyword controls whether to return a cartesian product of all possible groupers values (observed=False) or only those that are observed groupers (observed=True).

Show all values:

```
In [176]: pd.Series([1, 1, 1]).groupby(  
.....:     pd.Categorical(["a", "a", "a"], categories=["a", "b"]), observed=False  
.....: ).count()  
.....:  
Out[176]:  
a    3  
b    0  
dtype: int64
```

Show only the observed values:

```
In [177]: pd.Series([1, 1, 1]).groupby(  
.....:     pd.Categorical(["a", "a", "a"], categories=["a", "b"]), observed=True  
.....: ).count()  
.....:  
Out[177]:  
a    3  
dtype: int64
```

The returned dtype of the grouped will *always* include *all* of the categories that were grouped.

```
In [178]: s = (  
.....:     pd.Series([1, 1, 1])  
.....:     .groupby(pd.Categorical(["a", "a", "a"], categories=["a", "b"])),  
→ observed=False)  
.....:     .count()  
.....: )  
.....:  
  
In [179]: s.index.dtype  
Out[179]: CategoricalDtype(categories=['a', 'b'], ordered=False)
```

NA and NaT group handling

If there are any NaN or NaT values in the grouping key, these will be automatically excluded. In other words, there will never be an “NA group” or “NaT group”. This was not the case in older versions of pandas, but users were generally discarding the NA group anyway (and supporting it was an implementation headache).

Grouping with ordered factors

Categorical variables represented as instance of pandas’s Categorical class can be used as group keys. If so, the order of the levels will be preserved:

```
In [180]: data = pd.Series(np.random.randn(100))

In [181]: factor = pd.qcut(data, [0, 0.25, 0.5, 0.75, 1.0])

In [182]: data.groupby(factor).mean()
Out[182]:
(-2.645, -0.523]    -1.362896
(-0.523, 0.0296]    -0.260266
(0.0296, 0.654]     0.361802
(0.654, 2.21]       1.073801
dtype: float64
```

Grouping with a grouper specification

You may need to specify a bit more data to properly group. You can use the pd.Grouper to provide this local control.

```
In [183]: import datetime

In [184]: df = pd.DataFrame(
.....:     {
.....:         "Branch": "A A A A A A B".split(),
.....:         "Buyer": "Carl Mark Carl Carl Joe Joe Joe Carl".split(),
.....:         "Quantity": [1, 3, 5, 1, 8, 1, 9, 3],
.....:         "Date": [
.....:             datetime.datetime(2013, 1, 1, 13, 0),
.....:             datetime.datetime(2013, 1, 1, 13, 5),
.....:             datetime.datetime(2013, 10, 1, 20, 0),
.....:             datetime.datetime(2013, 10, 2, 10, 0),
.....:             datetime.datetime(2013, 10, 1, 20, 0),
.....:             datetime.datetime(2013, 10, 2, 10, 0),
.....:             datetime.datetime(2013, 12, 2, 12, 0),
.....:             datetime.datetime(2013, 12, 2, 14, 0),
.....:         ],
.....:     }
.....: )
.....:

In [185]: df
Out[185]:
   Branch Buyer  Quantity           Date
0       A  Carl        1 2013-01-01 13:00:00
```

(continues on next page)

(continued from previous page)

1	A	Mark	3	2013-01-01	13:05:00
2	A	Carl	5	2013-10-01	20:00:00
3	A	Carl	1	2013-10-02	10:00:00
4	A	Joe	8	2013-10-01	20:00:00
5	A	Joe	1	2013-10-02	10:00:00
6	A	Joe	9	2013-12-02	12:00:00
7	B	Carl	3	2013-12-02	14:00:00

Groupby a specific column with the desired frequency. This is like resampling.

In [186]: `df.groupby([pd.Grouper(freq="1M", key="Date"), "Buyer"]).sum()`

Out[186]:

Quantity		
Date	Buyer	
2013-01-31	Carl	1
	Mark	3
2013-10-31	Carl	6
	Joe	9
2013-12-31	Carl	3
	Joe	9

You have an ambiguous specification in that you have a named index and a column that could be potential groupers.

In [187]: `df = df.set_index("Date")`

In [188]: `df["Date"] = df.index + pd.offsets.MonthEnd(2)`

In [189]: `df.groupby([pd.Grouper(freq="6M", key="Date"), "Buyer"]).sum()`

Out[189]:

Quantity		
Date	Buyer	
2013-02-28	Carl	1
	Mark	3
2014-02-28	Carl	9
	Joe	18

In [190]: `df.groupby([pd.Grouper(freq="6M", level="Date"), "Buyer"]).sum()`

Out[190]:

Quantity		
Date	Buyer	
2013-01-31	Carl	1
	Mark	3
2014-01-31	Carl	9
	Joe	18

Taking the first rows of each group

Just like for a DataFrame or Series you can call head and tail on a groupby:

```
In [191]: df = pd.DataFrame([[1, 2], [1, 4], [5, 6]], columns=["A", "B"])

In [192]: df
Out[192]:
   A   B
0  1  2
1  1  4
2  5  6

In [193]: g = df.groupby("A")

In [194]: g.head(1)
Out[194]:
   A   B
0  1  2

In [195]: g.tail(1)
Out[195]:
   A   B
1  1  4
2  5  6
```

This shows the first or last n rows from each group.

Taking the nth row of each group

To select from a DataFrame or Series the nth item, use nth(). This is a reduction method, and will return a single row (or no row) per group if you pass an int for n:

```
In [196]: df = pd.DataFrame([[1, np.nan], [1, 4], [5, 6]], columns=["A", "B"])

In [197]: g = df.groupby("A")

In [198]: g.nth(0)
Out[198]:
          B
A
1    NaN
5    6.0

In [199]: g.nth(-1)
Out[199]:
          B
A
1    4.0
5    6.0

In [200]: g.nth(1)
```

(continues on next page)

(continued from previous page)

Out[200]:

```
B  
A  
1  4.0
```

If you want to select the nth not-null item, use the `dropna` kwarg. For a DataFrame this should be either 'any' or 'all' just like you would pass to `dropna`:

```
# nth(0) is the same as g.first()  
In [201]: g.nth(0, dropna="any")
```

Out[201]:

```
B  
A  
1  4.0  
5  6.0
```

```
In [202]: g.first()
```

Out[202]:

```
B  
A  
1  4.0  
5  6.0
```

```
# nth(-1) is the same as g.last()
```

```
In [203]: g.nth(-1, dropna="any") # NaNs denote group exhausted when using dropna
```

Out[203]:

```
B  
A  
1  4.0  
5  6.0
```

```
In [204]: g.last()
```

Out[204]:

```
B  
A  
1  4.0  
5  6.0
```

```
In [205]: g.B.nth(0, dropna="all")
```

Out[205]:

```
A  
1    4.0  
5    6.0  
Name: B, dtype: float64
```

As with other methods, passing `as_index=False`, will achieve a filtration, which returns the grouped row.

```
In [206]: df = pd.DataFrame([[1, np.nan], [1, 4], [5, 6]], columns=["A", "B"])
```

```
In [207]: g = df.groupby("A", as_index=False)
```

```
In [208]: g.nth(0)
```

(continues on next page)

(continued from previous page)

Out[208]:

	A	B
0	1	NaN
2	5	6.0

In [209]: g.nth(-1)**Out[209]:**

	A	B
1	1	4.0
2	5	6.0

You can also select multiple rows from each group by specifying multiple nth values as a list of ints.

In [210]: business_dates = pd.date_range(start="4/1/2014", end="6/30/2014", freq="B")**In [211]:** df = pd.DataFrame(1, index=business_dates, columns=["a", "b"])

get the first, 4th, and last date index for each month

In [212]: df.groupby([df.index.year, df.index.month]).nth([0, 3, -1])**Out[212]:**

	a	b
2014 4	1	1
4	1	1
4	1	1
5	1	1
5	1	1
5	1	1
6	1	1
6	1	1
6	1	1

Enumerate group items

To see the order in which each row appears within its group, use the `cumcount` method:

In [213]: dfg = pd.DataFrame(list("aaabba"), columns=["A"])**In [214]:** dfg**Out[214]:**

	A
0	a
1	a
2	a
3	b
4	b
5	a

In [215]: dfg.groupby("A").cumcount()**Out[215]:**

	0
1	1

(continues on next page)

(continued from previous page)

```
2    2
3    0
4    1
5    3
dtype: int64
```

In [216]: `dfg.groupby("A").cumcount(ascending=False)`

Out[216]:

```
0    3
1    2
2    1
3    1
4    0
5    0
dtype: int64
```

Enumerate groups

To see the ordering of the groups (as opposed to the order of rows within a group given by `cumcount`) you can use `ngroup()`.

Note that the numbers given to the groups match the order in which the groups would be seen when iterating over the `groupby` object, not the order they are first observed.

In [217]: `dfg = pd.DataFrame(list("aaabba"), columns=["A"])`

In [218]: `dfg`

Out[218]:

```
      A
0    a
1    a
2    a
3    b
4    b
5    a
```

In [219]: `dfg.groupby("A").ngroup()`

Out[219]:

```
0    0
1    0
2    0
3    1
4    1
5    0
dtype: int64
```

In [220]: `dfg.groupby("A").ngroup(ascending=False)`

Out[220]:

```
0    1
1    1
2    1
```

(continues on next page)

(continued from previous page)

```
3    0
4    0
5    1
dtype: int64
```

Plotting

Groupby also works with some plotting methods. For example, suppose we suspect that some features in a DataFrame may differ by group, in this case, the values in column 1 where the group is “B” are 3 higher on average.

```
In [221]: np.random.seed(1234)
```

```
In [222]: df = pd.DataFrame(np.random.randn(50, 2))
```

```
In [223]: df["g"] = np.random.choice(["A", "B"], size=50)
```

```
In [224]: df.loc[df["g"] == "B", 1] += 3
```

We can easily visualize this with a boxplot:

```
In [225]: df.groupby("g").boxplot()
```

Out[225]:

```
A      AxesSubplot(0.1,0.15;0.363636x0.75)
```

```
B      AxesSubplot(0.536364,0.15;0.363636x0.75)
```

```
dtype: object
```

The result of calling `boxplot` is a dictionary whose keys are the values of our grouping column `g` (“A” and “B”). The values of the resulting dictionary can be controlled by the `return_type` keyword of `boxplot`. See the [visualization documentation](#) for more.

Warning: For historical reasons, `df.groupby("g").boxplot()` is not equivalent to `df.boxplot(by="g")`. See [here](#) for an explanation.

Piping function calls

Similar to the functionality provided by `DataFrame` and `Series`, functions that take `GroupBy` objects can be chained together using a `pipe` method to allow for a cleaner, more readable syntax. To read about `.pipe` in general terms, see [here](#).

Combining `.groupby` and `.pipe` is often useful when you need to reuse `GroupBy` objects.

As an example, imagine having a `DataFrame` with columns for stores, products, revenue and quantity sold. We’d like to do a groupwise calculation of *prices* (i.e. revenue/quantity) per store and per product. We could do this in a multi-step operation, but expressing it in terms of piping can make the code more readable. First we set the data:

In [226]: `n = 1000`

In [227]: `df = pd.DataFrame(`

(continues on next page)

(continued from previous page)

```
        "Store": np.random.choice(["Store_1", "Store_2"], n),
        "Product": np.random.choice(["Product_1", "Product_2"], n),
        "Revenue": (np.random.random(n) * 50 + 10).round(2),
        "Quantity": np.random.randint(1, 10, size=n),
    }
}
```

In [228]: df.head(2)

Out[228]:

	Store	Product	Revenue	Quantity
0	Store_2	Product_1	26.12	1
1	Store_2	Product_1	28.86	1

Now, to find prices per store/product, we can simply do:

```
In [229]: (
    .....:     df.groupby(["Store", "Product"])
    .....:     .pipe(lambda grp: grp.Revenue.sum() / grp.Quantity.sum())
    .....:     .unstack()
    .....:     .round(2)
    .....: )
    .....:
```

Out[229]:

Product	Product_1	Product_2
Store		
Store_1	6.82	7.05
Store_2	6.30	6.64

Piping can also be expressive when you want to deliver a grouped object to some arbitrary function, for example:

```
In [230]: def mean(groupby):  
....:     return groupby.mean()  
....:
```

```
In [231]: df.groupby(["Store", "Product"]).pipe(mean)
```

Out[231]:

		Revenue	Quantity
Store	Product		
Store_1	Product_1	34.622727	5.075758
	Product_2	35.482815	5.029630
Store_2	Product_1	32.972837	5.237589
	Product_2	34.684360	5.224000

where `mean` takes a `GroupBy` object and finds the mean of the `Revenue` and `Quantity` columns respectively for each `Store-Product` combination. The `mean` function can be any function that takes in a `GroupBy` object; the `.pipe` will pass the `GroupBy` object as a parameter into the function you specify.

2.18.11 Examples

Regrouping by factor

Regroup columns of a DataFrame according to their sum, and sum the aggregated ones.

```
In [232]: df = pd.DataFrame({"a": [1, 0, 0], "b": [0, 1, 0], "c": [1, 0, 0], "d": [2, 3, 4]})

In [233]: df
Out[233]:
   a   b   c   d
0  1   0   1   2
1  0   1   0   3
2  0   0   0   4

In [234]: df.groupby(df.sum(), axis=1).sum()
Out[234]:
   1   9
0  2   2
1  1   3
2  0   4
```

Multi-column factorization

By using `ngroup()`, we can extract information about the groups in a way similar to `factorize()` (as described further in the [reshaping API](#)) but which applies naturally to multiple columns of mixed type and different sources. This can be useful as an intermediate categorical-like step in processing, when the relationships between the group rows are more important than their content, or as input to an algorithm which only accepts the integer encoding. (For more information about support in pandas for full categorical data, see the [Categorical introduction](#) and the [API documentation](#).)

```
In [235]: dfg = pd.DataFrame({"A": [1, 1, 2, 3, 2], "B": list("aaaba")})

In [236]: dfg
Out[236]:
   A   B
0  1   a
1  1   a
2  2   a
3  3   b
4  2   a

In [237]: dfg.groupby(["A", "B"]).ngroup()
Out[237]:
0    0
1    0
2    1
3    2
4    1
dtype: int64

In [238]: dfg.groupby(["A", [0, 0, 0, 1, 1]]).ngroup()
```

(continues on next page)

(continued from previous page)

Out[238]:

```
0    0
1    0
2    1
3    3
4    2
dtype: int64
```

Groupby by indexer to ‘resample’ data

Resampling produces new hypothetical samples (resamples) from already existing observed data or from a model that generates data. These new samples are similar to the pre-existing samples.

In order to resample to work on indices that are non-datetime-like, the following procedure can be utilized.

In the following examples, `df.index // 5` returns a binary array which is used to determine what gets selected for the groupby operation.

Note: The below example shows how we can downsample by consolidation of samples into fewer samples. Here by using `df.index // 5`, we are aggregating the samples in bins. By applying `std()` function, we aggregate the information contained in many samples into a small subset of values which is their standard deviation thereby reducing the number of samples.

In [239]: `df = pd.DataFrame(np.random.randn(10, 2))`
In [240]: `df`
Out[240]:

```
          0         1
0 -0.793893  0.321153
1  0.342250  1.618906
2 -0.975807  1.918201
3 -0.810847 -1.405919
4 -1.977759  0.461659
5  0.730057 -1.316938
6 -0.751328  0.528290
7 -0.257759 -1.081009
8  0.505895 -1.701948
9 -1.006349  0.020208
```

In [241]: `df.index // 5`
Out[241]: `Int64Index([0, 0, 0, 0, 0, 1, 1, 1, 1], dtype='int64')`
In [242]: `df.groupby(df.index // 5).std()`
Out[242]:

```
          0         1
0  0.823647  1.312912
1  0.760109  0.942941
```

Returning a Series to propagate names

Group DataFrame columns, compute a set of metrics and return a named Series. The Series name is used as the name for the column index. This is especially useful in conjunction with reshaping operations such as stacking in which the column index name will be used as the name of the inserted column:

```
In [243]: df = pd.DataFrame(  
.....:     {  
.....:         "a": [0, 0, 0, 0, 1, 1, 1, 1, 2, 2, 2, 2],  
.....:         "b": [0, 0, 1, 1, 0, 0, 1, 1, 0, 0, 1, 1],  
.....:         "c": [1, 0, 1, 0, 1, 0, 1, 0, 1, 0, 1, 0],  
.....:         "d": [0, 0, 0, 1, 0, 0, 0, 1, 0, 0, 0, 1],  
.....:     }  
.....:  
.....:  
In [244]: def compute_metrics(x):  
.....:     result = {"b_sum": x["b"].sum(), "c_mean": x["c"].mean()}  
.....:     return pd.Series(result, name="metrics")  
.....:  
In [245]: result = df.groupby("a").apply(compute_metrics)  
  
In [246]: result  
Out[246]:  
metrics    b_sum    c_mean  
a  
0          2.0      0.5  
1          2.0      0.5  
2          2.0      0.5  
  
In [247]: result.stack()  
Out[247]:  
a  metrics  
0  b_sum      2.0  
   c_mean      0.5  
1  b_sum      2.0  
   c_mean      0.5  
2  b_sum      2.0  
   c_mean      0.5  
dtype: float64
```

2.19 Windowing Operations

pandas contains a compact set of APIs for performing windowing operations - an operation that performs an aggregation over a sliding partition of values. The API functions similarly to the `groupby` API in that `Series` and `DataFrame` call the windowing method with necessary parameters and then subsequently call the aggregation function.

```
In [1]: s = pd.Series(range(5))  
  
In [2]: s.rolling(window=2).sum()
```

(continues on next page)

(continued from previous page)

Out[2]:

```
0      NaN
1      1.0
2      3.0
3      5.0
4      7.0
dtype: float64
```

The windows are comprised by looking back the length of the window from the current observation. The result above can be derived by taking the sum of the following windowed partitions of data:

```
In [3]: for window in s.rolling(window=2):
    ...:     print(window)
    ...:
0      0
dtype: int64
0      0
1      1
dtype: int64
1      1
2      2
dtype: int64
2      2
3      3
dtype: int64
3      3
4      4
dtype: int64
```

2.19.1 Overview

pandas supports 4 types of windowing operations:

1. Rolling window: Generic fixed or variable sliding window over the values.
2. Weighted window: Weighted, non-rectangular window supplied by the `scipy.signal` library.
3. Expanding window: Accumulating window over the values.
4. Exponentially Weighted window: Accumulating and exponentially weighted window over the values.

Concept	Method	Returned Object	Supports time-based windows	Supports chained groupby	Supports table method	Supports online operations
Rolling window	<code>rolling</code>	<code>Rolling</code>	Yes	Yes	Yes (as of version 1.3)	No
Weighted window	<code>rolling</code>	<code>Window</code>	No	No	No	No
Expanding window	<code>expand</code>	<code>Expanding</code>	No	Yes	Yes (as of version 1.3)	No
Exponentially Weighted window	<code>ewm</code>	<code>ExponentialMovingWindow</code>		Yes (as of version 1.2)	No	Yes (as of version 1.3)

As noted above, some operations support specifying a window based on a time offset:

```
In [4]: s = pd.Series(range(5), index=pd.date_range('2020-01-01', periods=5, freq='1D'))  
  
In [5]: s.rolling(window='2D').sum()  
Out[5]:  
2020-01-01    0.0  
2020-01-02    1.0  
2020-01-03    3.0  
2020-01-04    5.0  
2020-01-05    7.0  
Freq: D, dtype: float64
```

Additionally, some methods support chaining a `groupby` operation with a windowing operation which will first group the data by the specified keys and then perform a windowing operation per group.

```
In [6]: df = pd.DataFrame({'A': ['a', 'b', 'a', 'b', 'a'], 'B': range(5)})  
  
In [7]: df.groupby('A').expanding().sum()  
Out[7]:  
          B  
A  
a  0  0.0  
   2  2.0  
   4  6.0  
b  1  1.0  
   3  4.0
```

Note: Windowing operations currently only support numeric data (integer and float) and will always return `float64` values.

Warning: Some windowing aggregation, `mean`, `sum`, `var` and `std` methods may suffer from numerical imprecision due to the underlying windowing algorithms accumulating sums. When values differ with magnitude $1/np.finfo(np.double).eps$ this results in truncation. It must be noted, that large values may have an impact on windows, which do not include these values. `Kahan summation` is used to compute the rolling sums to preserve accuracy as much as possible.

New in version 1.3.0.

Some windowing operations also support the `method='table'` option in the constructor which performs the windowing operation over an entire `DataFrame` instead of a single column or row at a time. This can provide a useful performance benefit for a `DataFrame` with many columns or rows (with the corresponding `axis` argument) or the ability to utilize other columns during the windowing operation. The `method='table'` option can only be used if `engine='numba'` is specified in the corresponding method call.

For example, a `weighted mean` calculation can be calculated with `apply()` by specifying a separate column of weights.

```
In [8]: def weighted_mean(x):  
....:     arr = np.ones((1, x.shape[1]))  
....:     arr[:, :2] = (x[:, :2] * x[:, 2]).sum(axis=0) / x[:, 2].sum()  
....:     return arr
```

(continues on next page)

(continued from previous page)

```
....:
```

In [9]: df = pd.DataFrame([[1, 2, 0.6], [2, 3, 0.4], [3, 4, 0.2], [4, 5, 0.7]])

In [10]: df.rolling(2, method="table", min_periods=0).apply(weighted_mean, raw=True, ↵engine="numba") # noqa:E501

Out[10]:

	0	1	2
0	1.000000	2.000000	1.0
1	1.800000	2.000000	1.0
2	3.333333	2.333333	1.0
3	1.555556	7.000000	1.0

New in version 1.3.

Some windowing operations also support an `online` method after constructing a windowing object which returns a new object that supports passing in new `DataFrame` or `Series` objects to continue the windowing calculation with the new values (i.e. online calculations).

The methods on this new windowing objects must call the aggregation method first to “prime” the initial state of the online calculation. Then, new `DataFrame` or `Series` objects can be passed in the `update` argument to continue the windowing calculation.

```
In [11]: df = pd.DataFrame([[1, 2, 0.6], [2, 3, 0.4], [3, 4, 0.2], [4, 5, 0.7]])
```

In [12]: df.ewm(0.5).mean()

Out[12]:

	0	1	2
0	1.000000	2.000000	0.600000
1	1.750000	2.750000	0.450000
2	2.615385	3.615385	0.276923
3	3.550000	4.550000	0.562500

```
In [13]: online_ewm = df.head(2).ewm(0.5).online()
```

In [14]: online_ewm.mean()

Out[14]:

	0	1	2
0	1.00	2.00	0.60
1	1.75	2.75	0.45

In [15]: online_ewm.mean(update=df.tail(1))

Out[15]:

	0	1	2
3	3.307692	4.307692	0.623077

All windowing operations support a `min_periods` argument that dictates the minimum amount of non-`np.nan` values a window must have; otherwise, the resulting value is `np.nan`. `min_periods` defaults to 1 for time-based windows and `window` for fixed windows

```
In [16]: s = pd.Series([np.nan, 1, 2, np.nan, np.nan, 3])
```

In [17]: s.rolling(window=3, min_periods=1).sum()

(continues on next page)

(continued from previous page)

Out[17]:

```
0      NaN
1      1.0
2      3.0
3      3.0
4      2.0
5      3.0
dtype: float64
```

In [18]: s.rolling(window=3, min_periods=2).sum()**Out[18]:**

```
0      NaN
1      NaN
2      3.0
3      3.0
4      NaN
5      NaN
dtype: float64
```

Equivalent to min_periods=3

In [19]: s.rolling(window=3, min_periods=None).sum()**Out[19]:**

```
0      NaN
1      NaN
2      NaN
3      NaN
4      NaN
5      NaN
dtype: float64
```

Additionally, all windowing operations supports the aggregate method for returning a result of multiple aggregations applied to a window.

In [20]: df = pd.DataFrame({"A": range(5), "B": range(10, 15)})**In [21]:** df.expanding().agg([np.sum, np.mean, np.std])**Out[21]:**

	A			B		
	sum	mean	std	sum	mean	std
0	0.0	0.0	NaN	10.0	10.0	NaN
1	1.0	0.5	0.707107	21.0	10.5	0.707107
2	3.0	1.0	1.000000	33.0	11.0	1.000000
3	6.0	1.5	1.290994	46.0	11.5	1.290994
4	10.0	2.0	1.581139	60.0	12.0	1.581139

2.19.2 Rolling window

Generic rolling windows support specifying windows as a fixed number of observations or variable number of observations based on an offset. If a time based offset is provided, the corresponding time based index must be monotonic.

```
In [22]: times = ['2020-01-01', '2020-01-03', '2020-01-04', '2020-01-05', '2020-01-29']
```

```
In [23]: s = pd.Series(range(5), index=pd.DatetimeIndex(times))
```

```
In [24]: s
```

```
Out[24]:
```

2020-01-01	0
2020-01-03	1
2020-01-04	2
2020-01-05	3
2020-01-29	4

```
# Window with 2 observations
```

```
In [25]: s.rolling(window=2).sum()
```

```
Out[25]:
```

2020-01-01	NaN
2020-01-03	1.0
2020-01-04	3.0
2020-01-05	5.0
2020-01-29	7.0

```
# Window with 2 days worth of observations
```

```
In [26]: s.rolling(window='2D').sum()
```

```
Out[26]:
```

2020-01-01	0.0
2020-01-03	1.0
2020-01-04	3.0
2020-01-05	5.0
2020-01-29	4.0

For all supported aggregation functions, see [Rolling window functions](#).

Centering windows

By default the labels are set to the right edge of the window, but a `center` keyword is available so the labels can be set at the center.

```
In [27]: s = pd.Series(range(10))
```

```
In [28]: s.rolling(window=5).mean()
```

```
Out[28]:
```

0	NaN
1	NaN
2	NaN
3	NaN

(continues on next page)

(continued from previous page)

```
4    2.0
5    3.0
6    4.0
7    5.0
8    6.0
9    7.0
dtype: float64
```

In [29]: `s.rolling(window=5, center=True).mean()`

Out[29]:

```
0    NaN
1    NaN
2    2.0
3    3.0
4    4.0
5    5.0
6    6.0
7    7.0
8    NaN
9    NaN
dtype: float64
```

This can also be applied to datetime-like indices.

New in version 1.3.0.

```
In [30]: df = pd.DataFrame(
....:     {"A": [0, 1, 2, 3, 4]}, index=pd.date_range("2020", periods=5, freq="1D")
....:
....:
```

In [31]: `df`

Out[31]:

```
          A
2020-01-01  0
2020-01-02  1
2020-01-03  2
2020-01-04  3
2020-01-05  4
```

Rolling window endpoints

The inclusion of the interval endpoints in rolling window calculations can be specified with the `closed` parameter:

Value	Behavior
'right'	close right endpoint
'left'	close left endpoint
'both'	close both endpoints
'neither'	open endpoints

For example, having the right endpoint open is useful in many problems that require that there is no contamination from present information back to past information. This allows the rolling window to compute statistics “up to that point in time”, but not including that point in time.

```
In [34]: df = pd.DataFrame(
....:     {"x": 1},
....:     index=[
....:         pd.Timestamp("20130101 09:00:01"),
....:         pd.Timestamp("20130101 09:00:02"),
....:         pd.Timestamp("20130101 09:00:03"),
....:         pd.Timestamp("20130101 09:00:04"),
....:         pd.Timestamp("20130101 09:00:06"),
....:     ],
....: )

```

Custom window rolling

New in version 1.0.

In addition to accepting an integer or offset as a `window` argument, `rolling` also accepts a `BaseIndexer` subclass that allows a user to define a custom method for calculating window bounds. The `BaseIndexer` subclass will need to define a `get_window_bounds` method that returns a tuple of two arrays, the first being the starting indices of the windows and second being the ending indices of the windows. Additionally, `num_values`, `min_periods`, `center`, `closed` and will automatically be passed to `get_window_bounds` and the defined method must always accept these arguments.

For example, if we have the following `DataFrame`

```
In [40]: use_expanding = [True, False, True, False, True]

In [41]: use_expanding
Out[41]: [True, False, True, False, True]

In [42]: df = pd.DataFrame({"values": range(5)})

In [43]: df
Out[43]:
   values
0      0
1      1
2      2
3      3
4      4
```

and we want to use an expanding window where `use_expanding` is `True` otherwise a window of size 1, we can create the following `BaseIndexer` subclass:

```
In [2]: from pandas.api.indexers import BaseIndexer

In [3]: class CustomIndexer(BaseIndexer):
...:     def get_window_bounds(self, num_values, min_periods, center, closed):
...:         start = np.empty(num_values, dtype=np.int64)
...:         end = np.empty(num_values, dtype=np.int64)
...:         for i in range(num_values):
...:             if self.use_expanding[i]:
...:                 start[i] = 0
...:                 end[i] = i + 1
...:             else:
...:                 start[i] = i
...:                 end[i] = i + self.window_size
...:         return start, end

In [4]: indexer = CustomIndexer(window_size=1, use_expanding=use_expanding)

In [5]: df.rolling(indexer).sum()
Out[5]:
   values
0      0.0
1      1.0
2      3.0
```

(continues on next page)

(continued from previous page)

3	3.0
4	10.0

You can view other examples of `BaseIndexer` subclasses [here](#)

New in version 1.1.

One subclass of note within those examples is the `VariableOffsetWindowIndexer` that allows rolling operations over a non-fixed offset like a `BusinessDay`.

```
In [44]: from pandas.api.indexers import VariableOffsetWindowIndexer

In [45]: df = pd.DataFrame(range(10), index=pd.date_range("2020", periods=10))

In [46]: offset = pd.offsets.BDay(1)

In [47]: indexer = VariableOffsetWindowIndexer(index=df.index, offset=offset)

In [48]: df
Out[48]:

2020-01-09 8.0
2020-01-10 9.0
```

For some problems knowledge of the future is available for analysis. For example, this occurs when each data point is a full time series read from an experiment, and the task is to extract underlying conditions. In these cases it can be useful to perform forward-looking rolling window computations. `FixedForwardWindowIndexer` class is available for this purpose. This `BaseIndexer` subclass implements a closed fixed-width forward-looking rolling window, and we can use it as follows:

```
In [50]: from pandas.api.indexers import FixedForwardWindowIndexer
```

(continues on next page)

(continued from previous page)

```
In [51]: indexer = FixedForwardWindowIndexer(window_size=2)
```

```
In [52]: df.rolling(indexer, min_periods=1).sum()
```

```
Out[52]:
```

```
    0  
2020-01-01  1.0  
2020-01-02  3.0  
2020-01-03  5.0  
2020-01-04  7.0  
2020-01-05  9.0  
2020-01-06  11.0  
2020-01-07  13.0  
2020-01-08  15.0  
2020-01-09  17.0  
2020-01-10  9.0
```

We can also achieve this by using slicing, applying rolling aggregation, and then flipping the result as shown in example below:

```
In [53]: df = pd.DataFrame(  
....:     data=[  
....:         [pd.Timestamp("2018-01-01 00:00:00"), 100],  
....:         [pd.Timestamp("2018-01-01 00:00:01"), 101],  
....:         [pd.Timestamp("2018-01-01 00:00:03"), 103],  
....:         [pd.Timestamp("2018-01-01 00:00:04"), 111],  
....:     ],  
....:     columns=["time", "value"],  
....: ).set_index("time")  
....:
```

```
In [54]: df
```

```
Out[54]:
```

```
          value  
time  
2018-01-01 00:00:00    100  
2018-01-01 00:00:01    101  
2018-01-01 00:00:03    103  
2018-01-01 00:00:04    111
```

```
In [55]: reversed_df = df[::-1].rolling("2s").sum()[::-1]
```

```
In [56]: reversed_df
```

```
Out[56]:
```

```
          value  
time  
2018-01-01 00:00:00  201.0  
2018-01-01 00:00:01  101.0  
2018-01-01 00:00:03  214.0  
2018-01-01 00:00:04  111.0
```

Rolling apply

The `apply()` function takes an extra `func` argument and performs generic rolling computations. The `func` argument should be a single function that produces a single value from an ndarray input. `raw` specifies whether the windows are cast as `Series` objects (`raw=False`) or ndarray objects (`raw=True`).

```
In [57]: def mad(x):
....:     return np.fabs(x - x.mean()).mean()
....:

In [58]: s = pd.Series(range(10))

In [59]: s.rolling(window=4).apply(mad, raw=True)
Out[59]:
0      NaN
1      NaN
2      NaN
3    1.0
4    1.0
5    1.0
6    1.0
7    1.0
8    1.0
9    1.0
dtype: float64
```

Numba engine

New in version 1.0.

Additionally, `apply()` can leverage `Numba` if installed as an optional dependency. The `apply` aggregation can be executed using `Numba` by specifying `engine='numba'` and `engine_kwargs` arguments (`raw` must also be set to `True`). See [enhancing performance with Numba](#) for general usage of the arguments and performance considerations.

`Numba` will be applied in potentially two routines:

1. If `func` is a standard Python function, the engine will `JIT` the passed function. `func` can also be a JITed function in which case the engine will not JIT the function again.
2. The engine will JIT the for loop where the `apply` function is applied to each window.

The `engine_kwargs` argument is a dictionary of keyword arguments that will be passed into the `numba.jit` decorator. These keyword arguments will be applied to *both* the passed function (if a standard Python function) and the `apply` for loop over each window.

New in version 1.3.0.

`mean`, `median`, `max`, `min`, and `sum` also support the `engine` and `engine_kwargs` arguments.

Binary window functions

`cov()` and `corr()` can compute moving window statistics about two `Series` or any combination of `DataFrame/Series` or `DataFrame/DataFrame`. Here is the behavior in each case:

- two `Series`: compute the statistic for the pairing.
- `DataFrame/Series`: compute the statistics for each column of the DataFrame with the passed Series, thus returning a DataFrame.
- `DataFrame/DataFrame`: by default compute the statistic for matching column names, returning a DataFrame. If the keyword argument `pairwise=True` is passed then computes the statistic for each pair of columns, returning a `DataFrame` with a `MultiIndex` whose values are the dates in question (see [the next section](#)).

For example:

```
In [60]: df = pd.DataFrame(
....:     np.random.randn(10, 4),
....:     index=pd.date_range("2020-01-01", periods=10),
....:     columns=["A", "B", "C", "D"],
....:
....:

In [61]: df = df.cumsum()

In [62]: df2 = df[:4]

In [63]: df2.rolling(window=2).corr(df2["B"])
Out[63]:
      A      B      C      D
2020-01-01  NaN  NaN  NaN  NaN
2020-01-02 -1.0  1.0 -1.0  1.0
2020-01-03  1.0  1.0  1.0 -1.0
2020-01-04 -1.0  1.0  1.0 -1.0
```

Computing rolling pairwise covariances and correlations

In financial data analysis and other fields it's common to compute covariance and correlation matrices for a collection of time series. Often one is also interested in moving-window covariance and correlation matrices. This can be done by passing the `pairwise` keyword argument, which in the case of `DataFrame` inputs will yield a MultiIndexed `DataFrame` whose `index` are the dates in question. In the case of a single DataFrame argument the `pairwise` argument can even be omitted:

Note: Missing values are ignored and each entry is computed using the pairwise complete observations. Please see the [covariance section](#) for [caveats](#) associated with this method of calculating covariance and correlation matrices.

```
In [64]: cova = (
....:     df[["B", "C", "D"]]
....:     .rolling(window=4)
....:     .cov(df[["A", "B", "C"]], pairwise=True)
....:
....:
```

(continues on next page)

2.19.3 Weighted window

The `win_type` argument in `.rolling` generates a weighted windows that are commonly used in filtering and spectral estimation. `win_type` must be string that corresponds to a `scipy.signal` window function. Scipy must be installed in order to use these windows, and supplementary arguments that the Scipy window methods take must be specified in the aggregation function.

In [66]: s = pd.Series(range(10))**In [67]:** s.rolling(window=5).mean()**Out[67]:**

For all supported aggregation functions, see [Weighted window functions](#).

2.19.4 Expanding window

An expanding window yields the value of an aggregation statistic with all the data available up to that point in time. Since these calculations are a special case of rolling statistics, they are implemented in pandas such that the following two calls are equivalent:

```
In [70]: df = pd.DataFrame(range(5))

In [71]: df.rolling(window=len(df), min_periods=1).mean()
Out[71]:
0
0  0.0
1  0.5
2  1.0
3  1.5
4  2.0

In [72]: df.expanding(min_periods=1).mean()
Out[72]:
0
0  0.0
1  0.5
2  1.0
3  1.5
4  2.0
```

For all supported aggregation functions, see [Expanding window functions](#).

2.19.5 Exponentially Weighted window

An exponentially weighted window is similar to an expanding window but with each prior point being exponentially weighted down relative to the current point.

In general, a weighted moving average is calculated as

$$y_t = \frac{\sum_{i=0}^t w_i x_{t-i}}{\sum_{i=0}^t w_i},$$

where x_t is the input, y_t is the result and the w_i are the weights.

For all supported aggregation functions, see [Exponentially-weighted window functions](#).

The EW functions support two variants of exponential weights. The default, `adjust=True`, uses the weights $w_i = (1 - \alpha)^i$ which gives

$$y_t = \frac{x_t + (1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + \dots + (1 - \alpha)^t x_0}{1 + (1 - \alpha) + (1 - \alpha)^2 + \dots + (1 - \alpha)^t}$$

When `adjust=False` is specified, moving averages are calculated as

$$\begin{aligned} y_0 &= x_0 \\ y_t &= (1 - \alpha)y_{t-1} + \alpha x_t, \end{aligned}$$

which is equivalent to using weights

$$w_i = \begin{cases} \alpha(1 - \alpha)^i & \text{if } i < t \\ (1 - \alpha)^i & \text{if } i = t. \end{cases}$$

Note: These equations are sometimes written in terms of $\alpha' = 1 - \alpha$, e.g.

$$y_t = \alpha'y_{t-1} + (1 - \alpha')x_t.$$

The difference between the above two variants arises because we are dealing with series which have finite history. Consider a series of infinite history, with `adjust=True`:

$$y_t = \frac{x_t + (1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + \dots}{1 + (1 - \alpha) + (1 - \alpha)^2 + \dots}$$

Noting that the denominator is a geometric series with initial term equal to 1 and a ratio of $1 - \alpha$ we have

$$\begin{aligned} y_t &= \frac{x_t + (1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + \dots}{\frac{1}{1 - (1 - \alpha)}} \\ &= [x_t + (1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + \dots]\alpha \\ &= \alpha x_t + [(1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + \dots]\alpha \\ &= \alpha x_t + (1 - \alpha)[x_{t-1} + (1 - \alpha)x_{t-2} + \dots]\alpha \\ &= \alpha x_t + (1 - \alpha)y_{t-1} \end{aligned}$$

which is the same expression as `adjust=False` above and therefore shows the equivalence of the two variants for infinite series. When `adjust=False`, we have $y_0 = x_0$ and $y_t = \alpha x_t + (1 - \alpha)y_{t-1}$. Therefore, there is an assumption that x_0 is not an ordinary value but rather an exponentially weighted moment of the infinite series up to that point.

One must have $0 < \alpha \leq 1$, and while it is possible to pass α directly, it's often easier to think about either the **span**, **center of mass (com)** or **half-life** of an EW moment:

$$\alpha = \begin{cases} \frac{2}{s+1}, & \text{for span } s \geq 1 \\ \frac{1}{1+c}, & \text{for center of mass } c \geq 0 \\ 1 - \exp^{-\frac{\log 0.5}{h}}, & \text{for half-life } h > 0 \end{cases}$$

One must specify precisely one of **span**, **center of mass**, **half-life** and **alpha** to the EW functions:

- **Span** corresponds to what is commonly called an “N-day EW moving average”.
- **Center of mass** has a more physical interpretation and can be thought of in terms of span: $c = (s - 1)/2$.
- **Half-life** is the period of time for the exponential weight to reduce to one half.
- **Alpha** specifies the smoothing factor directly.

New in version 1.1.0.

You can also specify `halflife` in terms of a `timedelta` convertible unit to specify the amount of time it takes for an observation to decay to half its value when also specifying a sequence of `times`.

```
In [73]: df = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]})

In [74]: df
Out[74]:
   B
0  0.0
1  1.0
2  2.0
3  NaN
4  4.0

In [75]: times = ["2020-01-01", "2020-01-03", "2020-01-10", "2020-01-15", "2020-01-17"]

In [76]: df.ewm(halflife="4 days", times=pd.DatetimeIndex(times)).mean()
Out[76]:
   B
0  0.000000
1  0.585786
2  1.523889
3  1.523889
4  3.233686
```

The following formula is used to compute exponentially weighted mean with an input vector of times:

$$y_t = \frac{\sum_{i=0}^t 0.5^{\frac{t_i-t}{\lambda}} x_{t-i}}{\sum_{i=0}^t 0.5^{\frac{t_i-t}{\lambda}}},$$

`ExponentialMovingWindow` also has an `ignore_na` argument, which determines how intermediate null values affect the calculation of the weights. When `ignore_na=False` (the default), weights are calculated based on absolute positions, so that intermediate null values affect the result. When `ignore_na=True`, weights are calculated by ignoring intermediate null values. For example, assuming `adjust=True`, if `ignore_na=False`, the weighted average of 3, `NaN`, 5 would be calculated as

$$\frac{(1-\alpha)^2 \cdot 3 + 1 \cdot 5}{(1-\alpha)^2 + 1}.$$

Whereas if `ignore_na=True`, the weighted average would be calculated as

$$\frac{(1 - \alpha) \cdot 3 + 1 \cdot 5}{(1 - \alpha) + 1}.$$

The `var()`, `std()`, and `cov()` functions have a `bias` argument, specifying whether the result should contain biased or unbiased statistics. For example, if `bias=True`, `ewmvar(x)` is calculated as `ewmvar(x) = ewma(x**2) - ewma(x)**2`; whereas if `bias=False` (the default), the biased variance statistics are scaled by debiasing factors

$$\frac{\left(\sum_{i=0}^t w_i\right)^2}{\left(\sum_{i=0}^t w_i\right)^2 - \sum_{i=0}^t w_i^2}.$$

(For $w_i = 1$, this reduces to the usual $N/(N-1)$ factor, with $N = t+1$.) See [Weighted Sample Variance](#) on Wikipedia for further details.

2.20 Time series / date functionality

pandas contains extensive capabilities and features for working with time series data for all domains. Using the NumPy `datetime64` and `timedelta64` dtypes, pandas has consolidated a large number of features from other Python libraries like `scikits.timeseries` as well as created a tremendous amount of new functionality for manipulating time series data.

For example, pandas supports:

Parsing time series information from various sources and formats

```
In [1]: import datetime

In [2]: dti = pd.to_datetime(
...:     ["1/1/2018", np.datetime64("2018-01-01"), datetime.datetime(2018, 1, 1)]
...: )
...:

In [3]: dti
Out[3]: DatetimeIndex(['2018-01-01', '2018-01-01', '2018-01-01'],
   freq=None)
```

Generate sequences of fixed-frequency dates and time spans

```
In [4]: dti = pd.date_range("2018-01-01", periods=3, freq="H")

In [5]: dti
Out[5]:
DatetimeIndex(['2018-01-01 00:00:00', '2018-01-01 01:00:00',
               '2018-01-01 02:00:00'],
              dtype='datetime64[ns]', freq='H')
```

Manipulating and converting date times with timezone information

```
In [6]: dti = dti.tz_localize("UTC")

In [7]: dti
Out[7]:
```

(continues on next page)

(continued from previous page)

```
DatetimeIndex(['2018-01-01 00:00:00+00:00', '2018-01-01 01:00:00+00:00',
                 '2018-01-01 02:00:00+00:00'],
                dtype='datetime64[ns, UTC]', freq='H')
```

In [8]: dti.tz_convert("US/Pacific")

Out[8]:

```
DatetimeIndex(['2017-12-31 16:00:00-08:00', '2017-12-31 17:00:00-08:00',
                 '2017-12-31 18:00:00-08:00'],
                dtype='datetime64[ns, US/Pacific]', freq='H')
```

Resampling or converting a time series to a particular frequency

In [9]: idx = pd.date_range("2018-01-01", periods=5, freq="H")

In [10]: ts = pd.Series(range(len(idx)), index=idx)

In [11]: ts

Out[11]:

```
2018-01-01 00:00:00    0
2018-01-01 01:00:00    1
2018-01-01 02:00:00    2
2018-01-01 03:00:00    3
2018-01-01 04:00:00    4
```

Freq: H, dtype: int64

In [12]: ts.resample("2H").mean()

Out[12]:

```
2018-01-01 00:00:00    0.5
2018-01-01 02:00:00    2.5
2018-01-01 04:00:00    4.0
```

Freq: 2H, dtype: float64

Performing date and time arithmetic with absolute or relative time increments

In [13]: friday = pd.Timestamp("2018-01-05")

In [14]: friday.day_name()

Out[14]: 'Friday'

Add 1 day

In [15]: saturday = friday + pd.Timedelta("1 day")

In [16]: saturday.day_name()

Out[16]: 'Saturday'

Add 1 business day (Friday --> Monday)

In [17]: monday = friday + pd.offsets.BDay()

In [18]: monday.day_name()

Out[18]: 'Monday'

pandas provides a relatively compact and self-contained set of tools for performing the above tasks and more.

2.20.1 Overview

pandas captures 4 general time related concepts:

1. Date times: A specific date and time with timezone support. Similar to `datetime.datetime` from the standard library.
2. Time deltas: An absolute time duration. Similar to `datetime.timedelta` from the standard library.
3. Time spans: A span of time defined by a point in time and its associated frequency.
4. Date offsets: A relative time duration that respects calendar arithmetic. Similar to `dateutil.relativedelta.relativedelta` from the `dateutil` package.

Concept	Scalar Class	Array Class	pandas Data Type	Primary Creation Method
Date times	<code>Timestamp</code>	<code>DatetimeIndex</code>	<code>datetime64[ns]</code> <code>datetime64[ns, tz]</code>	<code>to_datetime</code> or <code>date_range</code>
Time deltas	<code>Timedelta</code>	<code>TimedeltaIndex</code>	<code>timedelta64[ns]</code>	<code>to_timedelta</code> or <code>timedelta_range</code>
Time spans	<code>Period</code>	<code>PeriodIndex</code>	<code>period[freq]</code>	<code>Period</code> or <code>period_range</code>
Date offsets	<code>DateOffset</code>	<code>None</code>	<code>None</code>	<code>DateOffset</code>

For time series data, it's conventional to represent the time component in the index of a `Series` or `DataFrame` so manipulations can be performed with respect to the time element.

```
In [19]: pd.Series(range(3), index=pd.date_range("2000", freq="D", periods=3))
Out[19]:
2000-01-01    0
2000-01-02    1
2000-01-03    2
Freq: D, dtype: int64
```

However, `Series` and `DataFrame` can directly also support the time component as data itself.

```
In [20]: pd.Series(pd.date_range("2000", freq="D", periods=3))
Out[20]:
0    2000-01-01
1    2000-01-02
2    2000-01-03
dtype: datetime64[ns]
```

`Series` and `DataFrame` have extended data type support and functionality for `datetime`, `timedelta` and `Period` data when passed into those constructors. `DateOffset` data however will be stored as `object` data.

```
In [21]: pd.Series(pd.period_range("1/1/2011", freq="M", periods=3))
Out[21]:
0    2011-01
1    2011-02
2    2011-03
dtype: period[M]
```

```
In [22]: pd.Series([pd.DateOffset(1), pd.DateOffset(2)])
```

(continues on next page)

(continued from previous page)

Out[22]:

```
0      <DateOffset>
1    <2 * DateOffsets>
dtype: object
```

In [23]: pd.Series(pd.date_range("1/1/2011", freq="M", periods=3))**Out[23]:**

```
0   2011-01-31
1   2011-02-28
2   2011-03-31
dtype: datetime64[ns]
```

Lastly, pandas represents null date times, time deltas, and time spans as NaT which is useful for representing missing or null date like values and behaves similar as np.nan does for float data.

In [24]: pd.Timestamp(pd.NaT)**Out[24]:** NaT**In [25]:** pd.Timedelta(pd.NaT)**Out[25]:** NaT**In [26]:** pd.Period(pd.NaT)**Out[26]:** NaT

Equality acts as np.nan would

In [27]: pd.NaT == pd.NaT**Out[27]:** False

2.20.2 Timestamps vs. time spans

Timestamped data is the most basic type of time series data that associates values with points in time. For pandas objects it means using the points in time.

In [28]: pd.Timestamp(datetime.datetime(2012, 5, 1))**Out[28]:** Timestamp('2012-05-01 00:00:00')**In [29]:** pd.Timestamp("2012-05-01")**Out[29]:** Timestamp('2012-05-01 00:00:00')**In [30]:** pd.Timestamp(2012, 5, 1)**Out[30]:** Timestamp('2012-05-01 00:00:00')

However, in many cases it is more natural to associate things like change variables with a time span instead. The span represented by Period can be specified explicitly, or inferred from datetime string format.

For example:

In [31]: pd.Period("2011-01")**Out[31]:** Period('2011-01', 'M')**In [32]:** pd.Period("2012-05", freq="D")**Out[32]:** Period('2012-05-01', 'D')

`Timestamp` and `Period` can serve as an index. Lists of `Timestamp` and `Period` are automatically coerced to `DatetimeIndex` and `PeriodIndex` respectively.

```
In [33]: dates = [
....:     pd.Timestamp("2012-05-01"),
....:     pd.Timestamp("2012-05-02"),
....:     pd.Timestamp("2012-05-03"),
....: ]
....:

In [34]: ts = pd.Series(np.random.randn(3), dates)

In [35]: type(ts.index)
Out[35]: pandas.core.indexes.datetimes.DatetimeIndex

In [36]: ts.index
Out[36]: DatetimeIndex(['2012-05-01', '2012-05-02', '2012-05-03'], dtype='datetime64[ns]
˓→', freq=None)

In [37]: ts
Out[37]:
2012-05-01    0.469112
2012-05-02   -0.282863
2012-05-03   -1.509059
dtype: float64

In [38]: periods = [pd.Period("2012-01"), pd.Period("2012-02"), pd.Period("2012-03")]

In [39]: ts = pd.Series(np.random.randn(3), periods)

In [40]: type(ts.index)
Out[40]: pandas.core.indexes.period.PeriodIndex

In [41]: ts.index
Out[41]: PeriodIndex(['2012-01', '2012-02', '2012-03'], dtype='period[M']')

In [42]: ts
Out[42]:
2012-01    -1.135632
2012-02     1.212112
2012-03    -0.173215
Freq: M, dtype: float64
```

pandas allows you to capture both representations and convert between them. Under the hood, pandas represents timestamps using instances of `Timestamp` and sequences of timestamps using instances of `DatetimeIndex`. For regular time spans, pandas uses `Period` objects for scalar values and `PeriodIndex` for sequences of spans. Better support for irregular intervals with arbitrary start and end points are forth-coming in future releases.

2.20.3 Converting to timestamps

To convert a `Series` or list-like object of date-like objects e.g. strings, epochs, or a mixture, you can use the `to_datetime` function. When passed a `Series`, this returns a `Series` (with the same index), while a list-like is converted to a `DatetimeIndex`:

```
In [43]: pd.to_datetime(pd.Series(["Jul 31, 2009", "2010-01-10", None]))  
Out[43]:  
0    2009-07-31  
1    2010-01-10  
2        NaT  
dtype: datetime64[ns]  
  
In [44]: pd.to_datetime(["2005/11/23", "2010.12.31"])  
Out[44]: DatetimeIndex(['2005-11-23', '2010-12-31'], dtype='datetime64[ns]', freq=None)
```

If you use dates which start with the day first (i.e. European style), you can pass the `dayfirst` flag:

```
In [45]: pd.to_datetime(["04-01-2012 10:00"], dayfirst=True)  
Out[45]: DatetimeIndex(['2012-01-04 10:00:00'], dtype='datetime64[ns]', freq=None)  
  
In [46]: pd.to_datetime(["14-01-2012", "01-14-2012"], dayfirst=True)  
Out[46]: DatetimeIndex(['2012-01-14', '2012-01-14'], dtype='datetime64[ns]', freq=None)
```

Warning: You see in the above example that `dayfirst` isn't strict. If a date can't be parsed with the day being first it will be parsed as if `dayfirst` were False, and in the case of parsing delimited date strings (e.g. 31-12-2012) then a warning will also be raised.

If you pass a single string to `to_datetime`, it returns a single `Timestamp`. `Timestamp` can also accept string input, but it doesn't accept string parsing options like `dayfirst` or `format`, so use `to_datetime` if these are required.

```
In [47]: pd.to_datetime("2010/11/12")  
Out[47]: Timestamp('2010-11-12 00:00:00')  
  
In [48]: pd.Timestamp("2010/11/12")  
Out[48]: Timestamp('2010-11-12 00:00:00')
```

You can also use the `DatetimeIndex` constructor directly:

```
In [49]: pd.DatetimeIndex(["2018-01-01", "2018-01-03", "2018-01-05"])  
Out[49]: DatetimeIndex(['2018-01-01', '2018-01-03', '2018-01-05'], dtype='datetime64[ns]  
˓→', freq=None)
```

The string 'infer' can be passed in order to set the frequency of the index as the inferred frequency upon creation:

```
In [50]: pd.DatetimeIndex(["2018-01-01", "2018-01-03", "2018-01-05"], freq="infer")  
Out[50]: DatetimeIndex(['2018-01-01', '2018-01-03', '2018-01-05'], dtype='datetime64[ns]  
˓→', freq='2D')
```

Providing a format argument

In addition to the required datetime string, a `format` argument can be passed to ensure specific parsing. This could also potentially speed up the conversion considerably.

```
In [51]: pd.to_datetime("2010/11/12", format="%Y/%m/%d")
Out[51]: Timestamp('2010-11-12 00:00:00')

In [52]: pd.to_datetime("12-11-2010 00:00", format="%d-%m-%Y %H:%M")
Out[52]: Timestamp('2010-11-12 00:00:00')
```

For more information on the choices available when specifying the `format` option, see the Python `datetime` documentation.

Assembling datetime from multiple DataFrame columns

You can also pass a `DataFrame` of integer or string columns to assemble into a `Series` of `Timestamps`.

```
In [53]: df = pd.DataFrame(
.....:     {"year": [2015, 2016], "month": [2, 3], "day": [4, 5], "hour": [2, 3]}
.....:
.....:

In [54]: pd.to_datetime(df)
Out[54]:
0    2015-02-04 02:00:00
1    2016-03-05 03:00:00
dtype: datetime64[ns]
```

You can pass only the columns that you need to assemble.

```
In [55]: pd.to_datetime(df[["year", "month", "day"]])
Out[55]:
0    2015-02-04
1    2016-03-05
dtype: datetime64[ns]
```

`pd.to_datetime` looks for standard designations of the datetime component in the column names, including:

- required: `year`, `month`, `day`
- optional: `hour`, `minute`, `second`, `millisecond`, `microsecond`, `nanosecond`

Invalid data

The default behavior, `errors='raise'`, is to raise when unparsable:

```
In [2]: pd.to_datetime(['2009/07/31', 'asd'], errors='raise')
ValueError: Unknown string format
```

Pass `errors='ignore'` to return the original input when unparsable:

```
In [56]: pd.to_datetime(["2009/07/31", "asd"], errors="ignore")
Out[56]: Index(['2009/07/31', 'asd'], dtype='object')
```

Pass `errors='coerce'` to convert unparsable data to NaT (not a time):

```
In [57]: pd.to_datetime(["2009/07/31", "asd"], errors="coerce")
Out[57]: DatetimeIndex(['2009-07-31', 'NaT'], dtype='datetime64[ns]', freq=None)
```

Epoch timestamps

pandas supports converting integer or float epoch times to `Timestamp` and `DatetimeIndex`. The default unit is nanoseconds, since that is how `Timestamp` objects are stored internally. However, epochs are often stored in another unit which can be specified. These are computed from the starting point specified by the `origin` parameter.

```
In [58]: pd.to_datetime(
    ....:     [1349720105, 1349806505, 1349892905, 1349979305, 1350065705], unit="s"
    ....:
    ....:
Out[58]:
DatetimeIndex(['2012-10-08 18:15:05', '2012-10-09 18:15:05',
               '2012-10-10 18:15:05', '2012-10-11 18:15:05',
               '2012-10-12 18:15:05'],
              dtype='datetime64[ns]', freq=None)

In [59]: pd.to_datetime(
    ....:     [1349720105100, 1349720105200, 1349720105300, 1349720105400, 1349720105500],
    ....:     unit="ms",
    ....:
    ....:
Out[59]:
DatetimeIndex(['2012-10-08 18:15:05.100000', '2012-10-08 18:15:05.200000',
               '2012-10-08 18:15:05.300000', '2012-10-08 18:15:05.400000',
               '2012-10-08 18:15:05.500000'],
              dtype='datetime64[ns]', freq=None)
```

Note: The `unit` parameter does not use the same strings as the `format` parameter that was discussed [above](#)). The available units are listed on the documentation for `pandas.to_datetime()`.

Changed in version 1.0.0.

Constructing a `Timestamp` or `DatetimeIndex` with an epoch timestamp with the `tz` argument specified will raise a `ValueError`. If you have epochs in wall time in another timezone, you can read the epochs as timezone-naive timestamps and then localize to the appropriate timezone:

```
In [60]: pd.Timestamp(1262347200000000000).tz_localize("US/Pacific")
Out[60]: Timestamp('2010-01-01 12:00:00-0800', tz='US/Pacific')

In [61]: pd.DatetimeIndex([1262347200000000000]).tz_localize("US/Pacific")
Out[61]: DatetimeIndex(['2010-01-01 12:00:00-08:00'], dtype='datetime64[ns, US/Pacific]',
   freq=None)
```

Note: Epoch times will be rounded to the nearest nanosecond.

Warning: Conversion of float epoch times can lead to inaccurate and unexpected results. Python floats have about 15 digits precision in decimal. Rounding during conversion from float to high precision Timestamp is unavoidable. The only way to achieve exact precision is to use a fixed-width types (e.g. an int64).

```
In [62]: pd.to_datetime([1490195805.433, 1490195805.433502912], unit="s")
Out[62]: DatetimeIndex(['2017-03-22 15:16:45.433000088', '2017-03-22 15:16:45.
˓→433502913'], dtype='datetime64[ns]', freq=None)

In [63]: pd.to_datetime(1490195805433502912, unit="ns")
Out[63]: Timestamp('2017-03-22 15:16:45.433502912')
```

See also:

Using the origin Parameter

From timestamps to epoch

To invert the operation from above, namely, to convert from a Timestamp to a ‘unix’ epoch:

```
In [64]: stamps = pd.date_range("2012-10-08 18:15:05", periods=4, freq="D")
In [65]: stamps
Out[65]:
DatetimeIndex(['2012-10-08 18:15:05', '2012-10-09 18:15:05',
               '2012-10-10 18:15:05', '2012-10-11 18:15:05'],
              dtype='datetime64[ns]', freq='D')
```

We subtract the epoch (midnight at January 1, 1970 UTC) and then floor divide by the “unit” (1 second).

```
In [66]: (stamps - pd.Timestamp("1970-01-01")) // pd.Timedelta("1s")
Out[66]: Int64Index([1349720105, 1349806505, 1349892905, 1349979305], dtype='int64')
```

Using the origin Parameter

Using the `origin` parameter, one can specify an alternative starting point for creation of a DatetimeIndex. For example, to use 1960-01-01 as the starting date:

```
In [67]: pd.to_datetime([1, 2, 3], unit="D", origin=pd.Timestamp("1960-01-01"))
Out[67]: DatetimeIndex(['1960-01-02', '1960-01-03', '1960-01-04'], dtype='datetime64[ns]
˓→', freq=None)
```

The default is set at `origin='unix'`, which defaults to 1970-01-01 00:00:00. Commonly called ‘unix epoch’ or POSIX time.

```
In [68]: pd.to_datetime([1, 2, 3], unit="D")
Out[68]: DatetimeIndex(['1970-01-02', '1970-01-03', '1970-01-04'], dtype='datetime64[ns]
˓→', freq=None)
```

2.20.4 Generating ranges of timestamps

To generate an index with timestamps, you can use either the `DatetimeIndex` or `Index` constructor and pass in a list of datetime objects:

```
In [69]: dates = [
....:     datetime.datetime(2012, 5, 1),
....:     datetime.datetime(2012, 5, 2),
....:     datetime.datetime(2012, 5, 3),
....: ]
....:

# Note the frequency information
In [70]: index = pd.DatetimeIndex(dates)

In [71]: index
Out[71]: DatetimeIndex(['2012-05-01', '2012-05-02', '2012-05-03'], dtype='datetime64[ns]
˓→', freq=None)

# Automatically converted to DatetimeIndex
In [72]: index = pd.Index(dates)

In [73]: index
Out[73]: DatetimeIndex(['2012-05-01', '2012-05-02', '2012-05-03'], dtype='datetime64[ns]
˓→', freq=None)
```

In practice this becomes very cumbersome because we often need a very long index with a large number of timestamps. If we need timestamps on a regular frequency, we can use the `date_range()` and `bdate_range()` functions to create a `DatetimeIndex`. The default frequency for `date_range` is a `calendar day` while the default for `bdate_range` is a `business day`:

```
In [74]: start = datetime.datetime(2011, 1, 1)

In [75]: end = datetime.datetime(2012, 1, 1)

In [76]: index = pd.date_range(start, end)

In [77]: index
Out[77]:
DatetimeIndex(['2011-01-01', '2011-01-02', '2011-01-03', '2011-01-04',
               '2011-01-05', '2011-01-06', '2011-01-07', '2011-01-08',
               '2011-01-09', '2011-01-10',
               ...
               '2011-12-23', '2011-12-24', '2011-12-25', '2011-12-26',
               '2011-12-27', '2011-12-28', '2011-12-29', '2011-12-30',
               '2011-12-31', '2012-01-01'],
              dtype='datetime64[ns]', length=366, freq='D')

In [78]: index = pd.bdate_range(start, end)

In [79]: index
Out[79]:
DatetimeIndex(['2011-01-03', '2011-01-04', '2011-01-05', '2011-01-06',
               '2011-01-07', '2011-01-10', '2011-01-11', '2011-01-12',
```

(continues on next page)

(continued from previous page)

```
'2011-01-13', '2011-01-14',
...
'2011-12-19', '2011-12-20', '2011-12-21', '2011-12-22',
'2011-12-23', '2011-12-26', '2011-12-27', '2011-12-28',
'2011-12-29', '2011-12-30'],
dtype='datetime64[ns]', length=260, freq='B')
```

Convenience functions like `date_range` and `bdate_range` can utilize a variety of *frequency aliases*:

In [80]: `pd.date_range(start, periods=1000, freq="M")`

Out[80]:

```
DatetimeIndex(['2011-01-31', '2011-02-28', '2011-03-31', '2011-04-30',
               '2011-05-31', '2011-06-30', '2011-07-31', '2011-08-31',
               '2011-09-30', '2011-10-31',
               ...
               '2093-07-31', '2093-08-31', '2093-09-30', '2093-10-31',
               '2093-11-30', '2093-12-31', '2094-01-31', '2094-02-28',
               '2094-03-31', '2094-04-30'],
              dtype='datetime64[ns]', length=1000, freq='M')
```

In [81]: `pd.bdate_range(start, periods=250, freq="BQS")`

Out[81]:

```
DatetimeIndex(['2011-01-03', '2011-04-01', '2011-07-01', '2011-10-03',
               '2012-01-02', '2012-04-02', '2012-07-02', '2012-10-01',
               '2013-01-01', '2013-04-01',
               ...
               '2071-01-01', '2071-04-01', '2071-07-01', '2071-10-01',
               '2072-01-01', '2072-04-01', '2072-07-01', '2072-10-03',
               '2073-01-02', '2073-04-03'],
              dtype='datetime64[ns]', length=250, freq='BQS-JAN')
```

`date_range` and `bdate_range` make it easy to generate a range of dates using various combinations of parameters like `start`, `end`, `periods`, and `freq`. The start and end dates are strictly inclusive, so dates outside of those specified will not be generated:

In [82]: `pd.date_range(start, end, freq="BM")`

Out[82]:

```
DatetimeIndex(['2011-01-31', '2011-02-28', '2011-03-31', '2011-04-29',
               '2011-05-31', '2011-06-30', '2011-07-29', '2011-08-31',
               '2011-09-30', '2011-10-31', '2011-11-30', '2011-12-30'],
              dtype='datetime64[ns]', freq='BM')
```

In [83]: `pd.date_range(start, end, freq="W")`

Out[83]:

```
DatetimeIndex(['2011-01-02', '2011-01-09', '2011-01-16', '2011-01-23',
               '2011-01-30', '2011-02-06', '2011-02-13', '2011-02-20',
               '2011-02-27', '2011-03-06', '2011-03-13', '2011-03-20',
               '2011-03-27', '2011-04-03', '2011-04-10', '2011-04-17',
               '2011-04-24', '2011-05-01', '2011-05-08', '2011-05-15',
               '2011-05-22', '2011-05-29', '2011-06-05', '2011-06-12',
               '2011-06-19', '2011-06-26', '2011-07-03', '2011-07-10',
               '2011-07-17', '2011-07-24', '2011-07-31', '2011-08-07'],
              dtype='datetime64[ns]', freq='W')
```

(continues on next page)

(continued from previous page)

```
'2011-08-14', '2011-08-21', '2011-08-28', '2011-09-04',
'2011-09-11', '2011-09-18', '2011-09-25', '2011-10-02',
'2011-10-09', '2011-10-16', '2011-10-23', '2011-10-30',
'2011-11-06', '2011-11-13', '2011-11-20', '2011-11-27',
'2011-12-04', '2011-12-11', '2011-12-18', '2011-12-25',
'2012-01-01'],
dtype='datetime64[ns]', freq='W-SUN')
```

In [84]: `pd.bdate_range(end=end, periods=20)`

Out[84]:

```
DatetimeIndex(['2011-12-05', '2011-12-06', '2011-12-07', '2011-12-08',
                '2011-12-09', '2011-12-12', '2011-12-13', '2011-12-14',
                '2011-12-15', '2011-12-16', '2011-12-19', '2011-12-20',
                '2011-12-21', '2011-12-22', '2011-12-23', '2011-12-26',
                '2011-12-27', '2011-12-28', '2011-12-29', '2011-12-30'],
               dtype='datetime64[ns]', freq='B')
```

In [85]: `pd.bdate_range(start=start, periods=20)`

Out[85]:

```
DatetimeIndex(['2011-01-03', '2011-01-04', '2011-01-05', '2011-01-06',
                '2011-01-07', '2011-01-10', '2011-01-11', '2011-01-12',
                '2011-01-13', '2011-01-14', '2011-01-17', '2011-01-18',
                '2011-01-19', '2011-01-20', '2011-01-21', '2011-01-24',
                '2011-01-25', '2011-01-26', '2011-01-27', '2011-01-28'],
               dtype='datetime64[ns]', freq='B')
```

Specifying `start`, `end`, and `periods` will generate a range of evenly spaced dates from `start` to `end` inclusively, with `periods` number of elements in the resulting `DatetimeIndex`:

In [86]: `pd.date_range("2018-01-01", "2018-01-05", periods=5)`

Out[86]:

```
DatetimeIndex(['2018-01-01', '2018-01-02', '2018-01-03', '2018-01-04',
                '2018-01-05'],
               dtype='datetime64[ns]', freq=None)
```

In [87]: `pd.date_range("2018-01-01", "2018-01-05", periods=10)`

Out[87]:

```
DatetimeIndex(['2018-01-01 00:00:00', '2018-01-01 10:40:00',
                '2018-01-01 21:20:00', '2018-01-02 08:00:00',
                '2018-01-02 18:40:00', '2018-01-03 05:20:00',
                '2018-01-03 16:00:00', '2018-01-04 02:40:00',
                '2018-01-04 13:20:00', '2018-01-05 00:00:00'],
               dtype='datetime64[ns]', freq=None)
```

Custom frequency ranges

`bdate_range` can also generate a range of custom frequency dates by using the `weekmask` and `holidays` parameters. These parameters will only be used if a custom frequency string is passed.

```
In [88]: weekmask = "Mon Wed Fri"

In [89]: holidays = [datetime.datetime(2011, 1, 5), datetime.datetime(2011, 3, 14)]

In [90]: pd.bdate_range(start, end, freq="C", weekmask=weekmask, holidays=holidays)
Out[90]:
DatetimeIndex(['2011-01-03', '2011-01-07', '2011-01-10', '2011-01-12',
               '2011-01-14', '2011-01-17', '2011-01-19', '2011-01-21',
               '2011-01-24', '2011-01-26',
               ...
               '2011-12-09', '2011-12-12', '2011-12-14', '2011-12-16',
               '2011-12-19', '2011-12-21', '2011-12-23', '2011-12-26',
               '2011-12-28', '2011-12-30'],
              dtype='datetime64[ns]', length=154, freq='C')

In [91]: pd.bdate_range(start, end, freq="CBMS", weekmask=weekmask)
Out[91]:
DatetimeIndex(['2011-01-03', '2011-02-02', '2011-03-02', '2011-04-01',
               '2011-05-02', '2011-06-01', '2011-07-01', '2011-08-01',
               '2011-09-02', '2011-10-03', '2011-11-02', '2011-12-02'],
              dtype='datetime64[ns]', freq='CBMS')
```

Custom business days

2.20.5 Timestamp limitations

Since pandas represents timestamps in nanosecond resolution, the time span that can be represented using a 64-bit integer is limited to approximately 584 years:

```
In [92]: pd.Timestamp.min
Out[92]: Timestamp('1677-09-21 00:12:43.145224193')

In [93]: pd.Timestamp.max
Out[93]: Timestamp('2262-04-11 23:47:16.854775807')
```

See also:

Representing out-of-bounds spans

2.20.6 Indexing

One of the main uses for `DatetimeIndex` is as an index for pandas objects. The `DatetimeIndex` class contains many time series related optimizations:

- A large range of dates for various offsets are pre-computed and cached under the hood in order to make generating subsequent date ranges very fast (just have to grab a slice).
- Fast shifting using the `shift` method on pandas objects.
- Unioning of overlapping `DatetimeIndex` objects with the same frequency is very fast (important for fast data alignment).
- Quick access to date fields via properties such as `year`, `month`, etc.
- Regularization functions like `snap` and very fast `asof` logic.

`DatetimeIndex` objects have all the basic functionality of regular `Index` objects, and a smorgasbord of advanced time series specific methods for easy frequency processing.

See also:

Reindexing methods

Note: While pandas does not force you to have a sorted date index, some of these methods may have unexpected or incorrect behavior if the dates are unsorted.

`DatetimeIndex` can be used like a regular index and offers all of its intelligent functionality like selection, slicing, etc.

```
In [94]: rng = pd.date_range(start, end, freq="BM")
```

```
In [95]: ts = pd.Series(np.random.randn(len(rng)), index=rng)
```

```
In [96]: ts.index
```

```
Out[96]:
```

```
DatetimeIndex(['2011-01-31', '2011-02-28', '2011-03-31', '2011-04-29',
                '2011-05-31', '2011-06-30', '2011-07-29', '2011-08-31',
                '2011-09-30', '2011-10-31', '2011-11-30', '2011-12-30'],
               dtype='datetime64[ns]', freq='BM')
```

```
In [97]: ts[:5].index
```

```
Out[97]:
```

```
DatetimeIndex(['2011-01-31', '2011-02-28', '2011-03-31', '2011-04-29',
                '2011-05-31'],
               dtype='datetime64[ns]', freq='BM')
```

```
In [98]: ts[::2].index
```

```
Out[98]:
```

```
DatetimeIndex(['2011-01-31', '2011-03-31', '2011-05-31', '2011-07-29',
                '2011-09-30', '2011-11-30'],
               dtype='datetime64[ns]', freq='2BM')
```

Partial string indexing

Dates and strings that parse to timestamps can be passed as indexing parameters:

```
In [99]: ts["1/31/2011"]
Out[99]: 0.11920871129693428

In [100]: ts[datetime.datetime(2011, 12, 25):]
Out[100]:
2011-12-30    0.56702
Freq: BM, dtype: float64

In [101]: ts["10/31/2011":"12/31/2011"]
Out[101]:
2011-10-31    0.271860
2011-11-30   -0.424972
2011-12-30    0.567020
Freq: BM, dtype: float64
```

To provide convenience for accessing longer time series, you can also pass in the year or year and month as strings:

```
In [102]: ts["2011"]
Out[102]:
2011-01-31    0.119209
2011-02-28   -1.044236
2011-03-31   -0.861849
2011-04-29   -2.104569
2011-05-31   -0.494929
2011-06-30    1.071804
2011-07-29    0.721555
2011-08-31   -0.706771
2011-09-30   -1.039575
2011-10-31    0.271860
2011-11-30   -0.424972
2011-12-30    0.567020
Freq: BM, dtype: float64

In [103]: ts["2011-6"]
Out[103]:
2011-06-30    1.071804
Freq: BM, dtype: float64
```

This type of slicing will work on a DataFrame with a DatetimeIndex as well. Since the partial string selection is a form of label slicing, the endpoints **will be** included. This would include matching times on an included date:

Warning: Indexing DataFrame rows with a *single* string with getitem (e.g. `frame[dtstring]`) is deprecated starting with pandas 1.2.0 (given the ambiguity whether it is indexing the rows or selecting a column) and will be removed in a future version. The equivalent with `.loc` (e.g. `frame.loc[dtstring]`) is still supported.

```
In [104]: dft = pd.DataFrame(
.....:     np.random.randn(100000, 1),
.....:     columns=["A"],
```

(continues on next page)

(continued from previous page)

```
.....:     index=pd.date_range("20130101", periods=100000, freq="T"),
.....: )
.....:
```

In [105]: dft

Out[105]:

```

2013-02-28 23:57:00 -2.693884
```

(continues on next page)

(continued from previous page)

```
2013-02-28 23:58:00 -1.575535
2013-02-28 23:59:00 -1.573517

[84960 rows x 1 columns]
```

This specifies a stop time **that includes all of the times on the last day**:

```
In [108]: dft["2013-1":"2013-2-28"]
Out[108]:
A
2013-01-01 00:00:00  0.276232
2013-01-01 00:01:00 -1.087401
2013-01-01 00:02:00 -0.673690
2013-01-01 00:03:00  0.113648
2013-01-01 00:04:00 -1.478427
...
...
2013-02-28 23:55:00  0.850929
2013-02-28 23:56:00  0.976712
2013-02-28 23:57:00 -2.693884
2013-02-28 23:58:00 -1.575535
2013-02-28 23:59:00 -1.573517

[84960 rows x 1 columns]
```

This specifies an **exact** stop time (and is not the same as the above):

```
In [109]: dft["2013-1":"2013-2-28 00:00:00"]
Out[109]:
A
2013-01-01 00:00:00  0.276232
2013-01-01 00:01:00 -1.087401
2013-01-01 00:02:00 -0.673690
2013-01-01 00:03:00  0.113648
2013-01-01 00:04:00 -1.478427
...
...
2013-02-27 23:56:00  1.197749
2013-02-27 23:57:00  0.720521
2013-02-27 23:58:00 -0.072718
2013-02-27 23:59:00 -0.681192
2013-02-28 00:00:00 -0.557501

[83521 rows x 1 columns]
```

We are stopping on the included end-point as it is part of the index:

```
In [110]: dft["2013-1-15":"2013-1-15 12:30:00"]
Out[110]:
A
2013-01-15 00:00:00 -0.984810
2013-01-15 00:01:00  0.941451
2013-01-15 00:02:00  1.559365
2013-01-15 00:03:00  1.034374
2013-01-15 00:04:00 -1.480656
```

(continues on next page)

(continued from previous page)

```
...
2013-01-15 12:26:00  0.371454
2013-01-15 12:27:00 -0.930806
2013-01-15 12:28:00 -0.069177
2013-01-15 12:29:00  0.066510
2013-01-15 12:30:00 -0.003945

[751 rows x 1 columns]
```

DatetimeIndex partial string indexing also works on a DataFrame with a MultiIndex:

```
In [111]: dft2 = pd.DataFrame(
.....:     np.random.randn(20, 1),
.....:     columns=["A"],
.....:     index=pd.MultiIndex.from_product(
.....:         [pd.date_range("2013-01-01", periods=10, freq="12H"), ["a", "b"]])
.....:     ),
.....: )

In [112]: dft2
Out[112]:
          A
2013-01-01 00:00:00 a -0.298694
                  b  0.823553
2013-01-01 12:00:00 a  0.943285
                  b -1.479399
2013-01-02 00:00:00 a -1.643342
...
2013-01-04 12:00:00 b  0.069036
2013-01-05 00:00:00 a  0.122297
                  b  1.422060
2013-01-05 12:00:00 a  0.370079
                  b  1.016331

[20 rows x 1 columns]

In [113]: dft2.loc["2013-01-05"]
Out[113]:
          A
2013-01-05 00:00:00 a  0.122297
                  b  1.422060
2013-01-05 12:00:00 a  0.370079
                  b  1.016331

In [114]: idx = pd.IndexSlice

In [115]: dft2 = dft2.swaplevel(0, 1).sort_index()

In [116]: dft2.loc[idx[:, "2013-01-05"], :]
Out[116]:
          A
```

(continues on next page)

(continued from previous page)

```
a 2013-01-05 00:00:00  0.122297
   2013-01-05 12:00:00  0.370079
b 2013-01-05 00:00:00  1.422060
   2013-01-05 12:00:00  1.016331
```

New in version 0.25.0.

Slicing with string indexing also honors UTC offset.

```
In [117]: df = pd.DataFrame([0], index=pd.DatetimeIndex(["2019-01-01"], tz="US/Pacific"))
```

```
In [118]: df
```

```
Out[118]:
```

```
0
2019-01-01 00:00:00-08:00 0
```

```
In [119]: df["2019-01-01 12:00:00+04:00":"2019-01-01 13:00:00+04:00"]
```

```
Out[119]:
```

```
0
2019-01-01 00:00:00-08:00 0
```

Slice vs. exact match

The same string used as an indexing parameter can be treated either as a slice or as an exact match depending on the resolution of the index. If the string is less accurate than the index, it will be treated as a slice, otherwise as an exact match.

Consider a `Series` object with a minute resolution index:

```
In [120]: series_minute = pd.Series(
.....:     [1, 2, 3],
.....:     pd.DatetimeIndex(
.....:         ["2011-12-31 23:59:00", "2012-01-01 00:00:00", "2012-01-01 00:02:00"]
.....:     ),
.....: )
.....:
```

```
In [121]: series_minute.index.resolution
```

```
Out[121]: 'minute'
```

A timestamp string less accurate than a minute gives a `Series` object.

```
In [122]: series_minute["2011-12-31 23"]
```

```
Out[122]:
```

```
2011-12-31 23:59:00    1
dtype: int64
```

A timestamp string with minute resolution (or more accurate), gives a scalar instead, i.e. it is not casted to a slice.

```
In [123]: series_minute["2011-12-31 23:59"]
```

```
Out[123]: 1
```

(continues on next page)

(continued from previous page)

```
In [124]: series_minute["2011-12-31 23:59:00"]
Out[124]: 1
```

If index resolution is second, then the minute-accurate timestamp gives a Series.

```
In [125]: series_second = pd.Series(
.....:     [1, 2, 3],
.....:     pd.DatetimeIndex(
.....:         ["2011-12-31 23:59:59", "2012-01-01 00:00:00", "2012-01-01 00:00:01"]
.....:     ),
.....: )
.....:
```

```
In [126]: series_second.index.resolution
Out[126]: 'second'
```

```
In [127]: series_second["2011-12-31 23:59"]
Out[127]:
2011-12-31 23:59:59    1
dtype: int64
```

If the timestamp string is treated as a slice, it can be used to index DataFrame with .loc[] as well.

```
In [128]: dft_minute = pd.DataFrame(
.....:     {"a": [1, 2, 3], "b": [4, 5, 6]}, index=series_minute.index
.....: )
.....:
```

```
In [129]: dft_minute.loc["2011-12-31 23"]
Out[129]:
      a   b
2011-12-31 23:59:00  1   4
```

Warning: However, if the string is treated as an exact match, the selection in DataFrame's [] will be column-wise and not row-wise, see [Indexing Basics](#). For example `dft_minute['2011-12-31 23:59']` will raise KeyError as '2012-12-31 23:59' has the same resolution as the index and there is no column with such name:

To *always* have unambiguous selection, whether the row is treated as a slice or a single selection, use .loc.

```
In [130]: dft_minute.loc["2011-12-31 23:59"]
Out[130]:
a    1
b    4
Name: 2011-12-31 23:59:00, dtype: int64
```

Note also that DatetimeIndex resolution cannot be less precise than day.

```
In [131]: series_monthly = pd.Series(
.....:     [1, 2, 3], pd.DatetimeIndex(["2011-12", "2012-01", "2012-02"]))
.....: )
.....:
```

(continues on next page)

(continued from previous page)

```
In [132]: series_monthly.index.resolution
Out[132]: 'day'

In [133]: series_monthly["2011-12"] # returns Series
Out[133]:
2011-12-01    1
dtype: int64
```

Exact indexing

As discussed in previous section, indexing a `DatetimeIndex` with a partial string depends on the “accuracy” of the period, in other words how specific the interval is in relation to the resolution of the index. In contrast, indexing with `Timestamp` or `datetime` objects is exact, because the objects have exact meaning. These also follow the semantics of *including both endpoints*.

These `Timestamp` and `datetime` objects have exact hours, minutes, and seconds, even though they were not explicitly specified (they are `0`).

```
In [134]: dft[datetime.datetime(2013, 1, 1): datetime.datetime(2013, 2, 28)]
Out[134]:
A
2013-01-01 00:00:00  0.276232
2013-01-01 00:01:00 -1.087401

2013-02-28 10:12:00  0.950146
```

```
[83521 rows x 1 columns]
```

Truncating & fancy indexing

A `truncate()` convenience function is provided that is similar to slicing. Note that `truncate` assumes a 0 value for any unspecified date component in a `DatetimeIndex` in contrast to slicing which returns any partially matching dates:

```
In [136]: rng2 = pd.date_range("2011-01-01", "2012-01-01", freq="W")
```

```
In [137]: ts2 = pd.Series(np.random.randn(len(rng2)), index=rng2)
```

```
In [138]: ts2.truncate(before="2011-11", after="2011-12")
```

```
Out[138]:
```

```
2011-11-06    0.437823
2011-11-13   -0.293083
2011-11-20   -0.059881
2011-11-27    1.252450
Freq: W-SUN, dtype: float64
```

```
In [139]: ts2["2011-11":"2011-12"]
```

```
Out[139]:
```

```
2011-11-06    0.437823
2011-11-13   -0.293083
2011-11-20   -0.059881
2011-11-27    1.252450
2011-12-04    0.046611
2011-12-11    0.059478
2011-12-18   -0.286539
2011-12-25    0.841669
Freq: W-SUN, dtype: float64
```

Even complicated fancy indexing that breaks the `DatetimeIndex` frequency regularity will result in a `DatetimeIndex`, although frequency is lost:

```
In [140]: ts2[[0, 2, 6]].index
```

```
Out[140]: DatetimeIndex(['2011-01-02', '2011-01-16', '2011-02-13'], dtype='datetime64[ns]
˓→', freq=None)
```

2.20.7 Time/date components

There are several time/date properties that one can access from `Timestamp` or a collection of timestamps like a `DatetimeIndex`.

Property	Description
<code>year</code>	The year of the datetime
<code>month</code>	The month of the datetime
<code>day</code>	The days of the datetime
<code>hour</code>	The hour of the datetime
<code>minute</code>	The minutes of the datetime
<code>second</code>	The seconds of the datetime
<code>microsecond</code>	The microseconds of the datetime
<code>nanosecond</code>	The nanoseconds of the datetime
<code>date</code>	Returns <code>datetime.date</code> (does not contain timezone information)
<code>time</code>	Returns <code>datetime.time</code> (does not contain timezone information)
<code>timetz</code>	Returns <code>datetime.time</code> as local time with timezone information
<code>dayofyear</code>	The ordinal day of year
<code>day_of_year</code>	The ordinal day of year
<code>weekofyear</code>	The week ordinal of the year
<code>week</code>	The week ordinal of the year
<code>dayofweek</code>	The number of the day of the week with Monday=0, Sunday=6
<code>day_of_week</code>	The number of the day of the week with Monday=0, Sunday=6
<code>weekday</code>	The number of the day of the week with Monday=0, Sunday=6
<code>quarter</code>	Quarter of the date: Jan-Mar = 1, Apr-Jun = 2, etc.
<code>days_in_month</code>	The number of days in the month of the datetime
<code>is_month_start</code>	Logical indicating if first day of month (defined by frequency)
<code>is_month_end</code>	Logical indicating if last day of month (defined by frequency)
<code>is_quarter_start</code>	Logical indicating if first day of quarter (defined by frequency)
<code>is_quarter_end</code>	Logical indicating if last day of quarter (defined by frequency)
<code>is_year_start</code>	Logical indicating if first day of year (defined by frequency)
<code>is_year_end</code>	Logical indicating if last day of year (defined by frequency)
<code>is_leap_year</code>	Logical indicating if the date belongs to a leap year

Furthermore, if you have a `Series` with datetimelike values, then you can access these properties via the `.dt` accessor, as detailed in the section on [.dt accessories](#).

New in version 1.1.0.

You may obtain the year, week and day components of the ISO year from the ISO 8601 standard:

```
In [141]: idx = pd.date_range(start="2019-12-29", freq="D", periods=4)
```

```
In [142]: idx.isocalendar()
```

```
Out[142]:
```

	year	week	day
2019-12-29	2019	52	7
2019-12-30	2020	1	1
2019-12-31	2020	1	2
2020-01-01	2020	1	3

```
In [143]: idx.to_series().dt.isocalendar()
```

```
Out[143]:
```

(continues on next page)

(continued from previous page)

	year	week	day
2019-12-29	2019	52	7
2019-12-30	2020	1	1
2019-12-31	2020	1	2
2020-01-01	2020	1	3

2.20.8 DateOffset objects

In the preceding examples, frequency strings (e.g. 'D') were used to specify a frequency that defined:

- how the date times in `DatetimeIndex` were spaced when using `date_range()`
- the frequency of a `Period` or `PeriodIndex`

These frequency strings map to a `DateOffset` object and its subclasses. A `DateOffset` is similar to a `Timedelta` that represents a duration of time but follows specific calendar duration rules. For example, a `Timedelta` day will always increment `datetimes` by 24 hours, while a `DateOffset` day will increment `datetimes` to the same time the next day whether a day represents 23, 24 or 25 hours due to daylight savings time. However, all `DateOffset` subclasses that are an hour or smaller (`Hour`, `Minute`, `Second`, `Milli`, `Micro`, `Nano`) behave like `Timedelta` and respect absolute time.

The basic `DateOffset` acts similar to `dateutil.relativedelta` ([relativedelta documentation](#)) that shifts a date time by the corresponding calendar duration specified. The arithmetic operator (+) can be used to perform the shift.

```
# This particular day contains a day light savings time transition
In [144]: ts = pd.Timestamp("2016-10-30 00:00:00", tz="Europe/Helsinki")

# Respects absolute time
In [145]: ts + pd.Timedelta(days=1)
Out[145]: Timestamp('2016-10-30 23:00:00+0200', tz='Europe/Helsinki')

# Respects calendar time
In [146]: ts + pd.DateOffset(days=1)
Out[146]: Timestamp('2016-10-31 00:00:00+0200', tz='Europe/Helsinki')

In [147]: friday = pd.Timestamp("2018-01-05")

In [148]: friday.day_name()
Out[148]: 'Friday'

# Add 2 business days (Friday --> Tuesday)
In [149]: two_business_days = 2 * pd.offsets.BDay()

In [150]: friday + two_business_days
Out[150]: Timestamp('2018-01-09 00:00:00')

In [151]: (friday + two_business_days).day_name()
Out[151]: 'Tuesday'
```

Most `DateOffsets` have associated frequencies strings, or offset aliases, that can be passed into `freq` keyword arguments. The available date offsets and associated frequency strings can be found below:

Date Offset	Frequency String	Description
<i>DateOffset</i>	None	Generic offset class, defaults to absolute 24 hours
<i>BDay</i> or <i>BusinessDay</i>	'B'	business day (weekday)
<i>CDay</i> or <i>CustomBusinessDay</i>	'C'	custom business day
<i>Week</i>	'W'	one week, optionally anchored on a day of the week
<i>WeekOfMonth</i>	'WOM'	the x-th day of the y-th week of each month
<i>LastWeekOfMonth</i>	'LWOM'	the x-th day of the last week of each month
<i>MonthEnd</i>	'M'	calendar month end
<i>MonthBegin</i>	'MS'	calendar month begin
<i>BMonthEnd</i> or <i>BusinessMonthEnd</i>	'BM'	business month end
<i>BMonthBegin</i> or <i>BusinessMonthBegin</i>	'BMS'	business month begin
<i>CBMonthEnd</i> or <i>CustomBusinessMonthEnd</i>	'CBM'	custom business month end
<i>CBMonthBegin</i> or <i>CustomBusinessMonthBegin</i>	'CBMS'	custom business month begin
<i>SemiMonthEnd</i>	'SM'	15th (or other day_of_month) and calendar month end
<i>SemiMonthBegin</i>	'SMS'	15th (or other day_of_month) and calendar month begin
<i>QuarterEnd</i>	'Q'	calendar quarter end
<i>QuarterBegin</i>	'QS'	calendar quarter begin
<i>BQuarterEnd</i>	'BQ'	business quarter end
<i>BQuarterBegin</i>	'BQS'	business quarter begin
<i>FY5253Quarter</i>	'REQ'	retail (aka 52-53 week) quarter
<i>YearEnd</i>	'A'	calendar year end
<i>YearBegin</i>	'AS' or 'BYS'	calendar year begin
<i>BYearEnd</i>	'BA'	business year end
<i>BYearBegin</i>	'BAS'	business year begin
<i>FY5253</i>	'RE'	retail (aka 52-53 week) year
<i>Easter</i>	None	Easter holiday
<i>BusinessHour</i>	'BH'	business hour
<i>CustomBusinessHour</i>	'CBH'	custom business hour
<i>Day</i>	'D'	one absolute day
<i>Hour</i>	'H'	one hour
<i>Minute</i>	'T' or 'min'	one minute
<i>Second</i>	'S'	one second
<i>Milli</i>	'L' or 'ms'	one millisecond
<i>Micro</i>	'U' or 'us'	one microsecond
<i>Nano</i>	'N'	one nanosecond

DateOffsets additionally have `rollforward()` and `rollback()` methods for moving a date forward or backward respectively to a valid offset date relative to the offset. For example, business offsets will roll dates that land on the weekends (Saturday and Sunday) forward to Monday since business offsets operate on the weekdays.

```
In [152]: ts = pd.Timestamp("2018-01-06 00:00:00")
```

(continues on next page)

(continued from previous page)

```
In [153]: ts.day_name()
Out[153]: 'Saturday'

# BusinessHour's valid offset dates are Monday through Friday
In [154]: offset = pd.offsets.BusinessHour(start="09:00")

# Bring the date to the closest offset date (Monday)
In [155]: offset.rollforward(ts)
Out[155]: Timestamp('2018-01-08 09:00:00')

# Date is brought to the closest offset date first and then the hour is added
In [156]: ts + offset
Out[156]: Timestamp('2018-01-08 10:00:00')
```

These operations preserve time (hour, minute, etc) information by default. To reset time to midnight, use `normalize()` before or after applying the operation (depending on whether you want the time information included in the operation).

```
In [157]: ts = pd.Timestamp("2014-01-01 09:00")

In [158]: day = pd.offsets.Day()

In [159]: day + ts
Out[159]: Timestamp('2014-01-02 09:00:00')

In [160]: (day + ts).normalize()
Out[160]: Timestamp('2014-01-02 00:00:00')

In [161]: ts = pd.Timestamp("2014-01-01 22:00")

In [162]: hour = pd.offsets.Hour()

In [163]: hour + ts
Out[163]: Timestamp('2014-01-01 23:00:00')

In [164]: (hour + ts).normalize()
Out[164]: Timestamp('2014-01-01 00:00:00')

In [165]: (hour + pd.Timestamp("2014-01-01 23:30")).normalize()
Out[165]: Timestamp('2014-01-02 00:00:00')
```

Parametric offsets

Some of the offsets can be “parameterized” when created to result in different behaviors. For example, the `Week` offset for generating weekly data accepts a `weekday` parameter which results in the generated dates always lying on a particular day of the week:

```
In [166]: d = datetime.datetime(2008, 8, 18, 9, 0)

In [167]: d
Out[167]: datetime.datetime(2008, 8, 18, 9, 0)
```

(continues on next page)

(continued from previous page)

```
In [168]: d + pd.offsets.Week()
Out[168]: Timestamp('2008-08-25 09:00:00')
```

```
In [169]: d + pd.offsets.Week(weekday=4)
Out[169]: Timestamp('2008-08-22 09:00:00')
```

```
In [170]: (d + pd.offsets.Week(weekday=4)).weekday()
Out[170]: 4
```

```
In [171]: d - pd.offsets.Week()
Out[171]: Timestamp('2008-08-11 09:00:00')
```

The `normalize` option will be effective for addition and subtraction.

```
In [172]: d + pd.offsets.Week(normalize=True)
Out[172]: Timestamp('2008-08-25 00:00:00')
```

```
In [173]: d - pd.offsets.Week(normalize=True)
Out[173]: Timestamp('2008-08-11 00:00:00')
```

Another example is parameterizing `YearEnd` with the specific ending month:

```
In [174]: d + pd.offsets.YearEnd()
Out[174]: Timestamp('2008-12-31 09:00:00')
```

```
In [175]: d + pd.offsets.YearEnd(month=6)
Out[175]: Timestamp('2009-06-30 09:00:00')
```

Using offsets with Series / DatetimeIndex

Offsets can be used with either a Series or DatetimeIndex to apply the offset to each element.

```
In [176]: rng = pd.date_range("2012-01-01", "2012-01-03")
```

```
In [177]: s = pd.Series(rng)
```

```
In [178]: rng
Out[178]: DatetimeIndex(['2012-01-01', '2012-01-02', '2012-01-03'], dtype='datetime64[ns]
˓→', freq='D')
```

```
In [179]: rng + pd.DateOffset(months=2)
Out[179]: DatetimeIndex(['2012-03-01', '2012-03-02', '2012-03-03'], dtype='datetime64[ns]
˓→', freq=None)
```

```
In [180]: s + pd.DateOffset(months=2)
```

```
Out[180]:
0    2012-03-01
1    2012-03-02
2    2012-03-03
dtype: datetime64[ns]
```

(continues on next page)

(continued from previous page)

```
In [181]: s = pd.DateOffset(months=2)
Out[181]:
0    2011-11-01
1    2011-11-02
2    2011-11-03
dtype: datetime64[ns]
```

If the offset class maps directly to a Timedelta (Day, Hour, Minute, Second, Micro, Milli, Nano) it can be used exactly like a Timedelta - see the [Timedelta section](#) for more examples.

```
In [182]: s = pd.offsets.Day(2)
Out[182]:
0    2011-12-30
1    2011-12-31
2    2012-01-01
dtype: datetime64[ns]

In [183]: td = s = pd.Series(pd.date_range("2011-12-29", "2011-12-31"))

In [184]: td
Out[184]:
0    3 days
1    3 days
2    3 days
dtype: timedelta64[ns]

In [185]: td + pd.offsets.Minute(15)
Out[185]:
0    3 days 00:15:00
1    3 days 00:15:00
2    3 days 00:15:00
dtype: timedelta64[ns]
```

Note that some offsets (such as BQuarterEnd) do not have a vectorized implementation. They can still be used but may calculate significantly slower and will show a `PerformanceWarning`

```
In [186]: rng + pd.offsets.BQuarterEnd()
Out[186]: DatetimeIndex(['2012-03-30', '2012-03-30', '2012-03-30'],
                           freq=None)
```

Custom business days

The CDay or CustomBusinessDay class provides a parametric BusinessDay class which can be used to create customized business day calendars which account for local holidays and local weekend conventions.

As an interesting example, let's look at Egypt where a Friday-Saturday weekend is observed.

```
In [187]: weekmask_egypt = "Sun Mon Tue Wed Thu"

# They also observe International Workers' Day so let's
# add that for a couple of years
In [188]: holidays = [
```

(continues on next page)

(continued from previous page)

```

....:     "2012-05-01",
....:     datetime.datetime(2013, 5, 1),
....:     np.datetime64("2014-05-01"),
....: ]
....:

In [189]: bday_egypt = pd.offsets.CustomBusinessDay(
....:         holidays=holidays,
....:         weekmask=weekmask_egypt,
....:         )
....:

In [190]: dt = datetime.datetime(2013, 4, 30)

In [191]: dt + 2 * bday_egypt
Out[191]: Timestamp('2013-05-05 00:00:00')

```

Let's map to the weekday names:

```

In [192]: dts = pd.date_range(dt, periods=5, freq=bday_egypt)

In [193]: pd.Series(dts.weekday, dts).map(pd.Series("Mon Tue Wed Thu Fri Sat Sun".
    ↪split()))
Out[193]:
2013-04-30    Tue
2013-05-02    Thu
2013-05-05    Sun
2013-05-06    Mon
2013-05-07    Tue
Freq: C, dtype: object

```

Holiday calendars can be used to provide the list of holidays. See the [holiday calendar](#) section for more information.

```

In [194]: from pandas.tseries.holiday import USFederalHolidayCalendar

In [195]: bday_us = pd.offsets.CustomBusinessDay(calendar=USFederalHolidayCalendar())

# Friday before MLK Day
In [196]: dt = datetime.datetime(2014, 1, 17)

# Tuesday after MLK Day (Monday is skipped because it's a holiday)
In [197]: dt + bday_us
Out[197]: Timestamp('2014-01-21 00:00:00')

```

Monthly offsets that respect a certain holiday calendar can be defined in the usual way.

```

In [198]: bmth_us = pd.offsets.
    ↪CustomBusinessMonthBegin(calendar=USFederalHolidayCalendar())

# Skip new years
In [199]: dt = datetime.datetime(2013, 12, 17)

In [200]: dt + bmth_us

```

(continues on next page)

(continued from previous page)

```
Out[200]: Timestamp('2014-01-02 00:00:00')

# Define date index with custom offset
In [201]: pd.date_range(start="20100101", end="20120101", freq=bmth_us)
Out[201]:
DatetimeIndex(['2010-01-04', '2010-02-01', '2010-03-01', '2010-04-01',
               '2010-05-03', '2010-06-01', '2010-07-01', '2010-08-02',
               '2010-09-01', '2010-10-01', '2010-11-01', '2010-12-01',
               '2011-01-03', '2011-02-01', '2011-03-01', '2011-04-01',
               '2011-05-02', '2011-06-01', '2011-07-01', '2011-08-01',
               '2011-09-01', '2011-10-03', '2011-11-01', '2011-12-01'],
              dtype='datetime64[ns]', freq='CBMS')
```

Note: The frequency string ‘C’ is used to indicate that a CustomBusinessDay DateOffset is used, it is important to note that since CustomBusinessDay is a parameterised type, instances of CustomBusinessDay may differ and this is not detectable from the ‘C’ frequency string. The user therefore needs to ensure that the ‘C’ frequency string is used consistently within the user’s application.

Business hour

The BusinessHour class provides a business hour representation on BusinessDay, allowing to use specific start and end times.

By default, BusinessHour uses 9:00 - 17:00 as business hours. Adding BusinessHour will increment Timestamp by hourly frequency. If target Timestamp is out of business hours, move to the next business hour then increment it. If the result exceeds the business hours end, the remaining hours are added to the next business day.

```
In [202]: bh = pd.offsets.BusinessHour()

In [203]: bh
Out[203]: <BusinessHour: BH=09:00-17:00>

# 2014-08-01 is Friday
In [204]: pd.Timestamp("2014-08-01 10:00").weekday()
Out[204]: 4

In [205]: pd.Timestamp("2014-08-01 10:00") + bh
Out[205]: Timestamp('2014-08-01 11:00:00')

# Below example is the same as: pd.Timestamp('2014-08-01 09:00') + bh
In [206]: pd.Timestamp("2014-08-01 08:00") + bh
Out[206]: Timestamp('2014-08-01 10:00:00')

# If the results is on the end time, move to the next business day
In [207]: pd.Timestamp("2014-08-01 16:00") + bh
Out[207]: Timestamp('2014-08-04 09:00:00')

# Remainings are added to the next day
In [208]: pd.Timestamp("2014-08-01 16:30") + bh
Out[208]: Timestamp('2014-08-04 09:30:00')
```

(continues on next page)

(continued from previous page)

```
# Adding 2 business hours
In [209]: pd.Timestamp("2014-08-01 10:00") + pd.offsets.BusinessHour(2)
Out[209]: Timestamp('2014-08-01 12:00:00')

# Subtracting 3 business hours
In [210]: pd.Timestamp("2014-08-01 10:00") + pd.offsets.BusinessHour(-3)
Out[210]: Timestamp('2014-07-31 15:00:00')
```

You can also specify `start` and `end` time by keywords. The argument must be a `str` with an `hour:minute` representation or a `datetime.time` instance. Specifying seconds, microseconds and nanoseconds as business hour results in `ValueError`.

```
In [211]: bh = pd.offsets.BusinessHour(start="11:00", end=datetime.time(20, 0))

In [212]: bh
Out[212]: <BusinessHour: BH=11:00-20:00>

In [213]: pd.Timestamp("2014-08-01 13:00") + bh
Out[213]: Timestamp('2014-08-01 14:00:00')

In [214]: pd.Timestamp("2014-08-01 09:00") + bh
Out[214]: Timestamp('2014-08-01 12:00:00')

In [215]: pd.Timestamp("2014-08-01 18:00") + bh
Out[215]: Timestamp('2014-08-01 19:00:00')
```

Passing `start` time later than `end` represents midnight business hour. In this case, business hour exceeds midnight and overlap to the next day. Valid business hours are distinguished by whether it started from valid `BusinessDay`.

```
In [216]: bh = pd.offsets.BusinessHour(start="17:00", end="09:00")

In [217]: bh
Out[217]: <BusinessHour: BH=17:00-09:00>

In [218]: pd.Timestamp("2014-08-01 17:00") + bh
Out[218]: Timestamp('2014-08-01 18:00:00')

In [219]: pd.Timestamp("2014-08-01 23:00") + bh
Out[219]: Timestamp('2014-08-02 00:00:00')

# Although 2014-08-02 is Saturday,
# it is valid because it starts from 08-01 (Friday).
In [220]: pd.Timestamp("2014-08-02 04:00") + bh
Out[220]: Timestamp('2014-08-02 05:00:00')

# Although 2014-08-04 is Monday,
# it is out of business hours because it starts from 08-03 (Sunday).
In [221]: pd.Timestamp("2014-08-04 04:00") + bh
Out[221]: Timestamp('2014-08-04 18:00:00')
```

Applying `BusinessHour.rollforward` and `rollback` to out of business hours results in the next business hour start or previous day's end. Different from other offsets, `BusinessHour.rollforward` may output different results from

apply by definition.

This is because one day's business hour end is equal to next day's business hour start. For example, under the default business hours (9:00 - 17:00), there is no gap (0 minutes) between 2014-08-01 17:00 and 2014-08-04 09:00.

```
# This adjusts a Timestamp to business hour edge
In [222]: pd.offsets.BusinessHour().rollback(pd.Timestamp("2014-08-02 15:00"))
Out[222]: Timestamp('2014-08-01 17:00:00')

In [223]: pd.offsets.BusinessHour().rollforward(pd.Timestamp("2014-08-02 15:00"))
Out[223]: Timestamp('2014-08-04 09:00:00')

# It is the same as BusinessHour() + pd.Timestamp('2014-08-01 17:00').
# And it is the same as BusinessHour() + pd.Timestamp('2014-08-04 09:00')
In [224]: pd.offsets.BusinessHour() + pd.Timestamp("2014-08-02 15:00")
Out[224]: Timestamp('2014-08-04 10:00:00')

# BusinessDay results (for reference)
In [225]: pd.offsets.BusinessHour().rollforward(pd.Timestamp("2014-08-02"))
Out[225]: Timestamp('2014-08-04 09:00:00')

# It is the same as BusinessDay() + pd.Timestamp('2014-08-01')
# The result is the same as rollwoward because BusinessDay never overlap.
In [226]: pd.offsets.BusinessHour() + pd.Timestamp("2014-08-02")
Out[226]: Timestamp('2014-08-04 10:00:00')
```

BusinessHour regards Saturday and Sunday as holidays. To use arbitrary holidays, you can use CustomBusinessHour offset, as explained in the following subsection.

Custom business hour

The CustomBusinessHour is a mixture of BusinessHour and CustomBusinessDay which allows you to specify arbitrary holidays. CustomBusinessHour works as the same as BusinessHour except that it skips specified custom holidays.

```
In [227]: from pandas.tseries.holiday import USFederalHolidayCalendar

In [228]: bhour_us = pd.offsets.CustomBusinessHour(calendar=USFederalHolidayCalendar())

# Friday before MLK Day
In [229]: dt = datetime.datetime(2014, 1, 17, 15)

In [230]: dt + bhour_us
Out[230]: Timestamp('2014-01-17 16:00:00')

# Tuesday after MLK Day (Monday is skipped because it's a holiday)
In [231]: dt + bhour_us * 2
Out[231]: Timestamp('2014-01-21 09:00:00')
```

You can use keyword arguments supported by either BusinessHour and CustomBusinessDay.

```
In [232]: bhour_mon = pd.offsets.CustomBusinessHour(start="10:00", weekmask="Tue Wed Thu
↪Fri")
```

(continues on next page)

(continued from previous page)

```
# Monday is skipped because it's a holiday, business hour starts from 10:00
In [233]: dt + bhour_mon * 2
Out[233]: Timestamp('2014-01-21 10:00:00')
```

Offset aliases

A number of string aliases are given to useful common time series frequencies. We will refer to these aliases as *offset aliases*.

Alias	Description
B	business day frequency
C	custom business day frequency
D	calendar day frequency
W	weekly frequency
M	month end frequency
SM	semi-month end frequency (15th and end of month)
BM	business month end frequency
CBM	custom business month end frequency
MS	month start frequency
SMS	semi-month start frequency (1st and 15th)
BMS	business month start frequency
CBMS	custom business month start frequency
Q	quarter end frequency
BQ	business quarter end frequency
QS	quarter start frequency
BQS	business quarter start frequency
A, Y	year end frequency
BA, BY	business year end frequency
AS, YS	year start frequency
BAS, BYS	business year start frequency
BH	business hour frequency
H	hourly frequency
T, min	minutely frequency
S	secondly frequency
L, ms	milliseconds
U, us	microseconds
N	nanoseconds

Note:

When using the offset aliases above, it should be noted that functions such as `date_range()`, `bdate_range()`, will only return timestamps that are in the interval defined by `start_date` and `end_date`. If the `start_date` does not correspond to the frequency, the returned timestamps will start at the next valid timestamp, same for `end_date`, the returned timestamps will stop at the previous valid timestamp.

For example, for the offset MS, if the `start_date` is not the first of the month, the returned timestamps will start with the first day of the next month. If `end_date` is not the first day of a month, the last returned timestamp will be the first day of the corresponding month.

```
In [234]: dates_lst_1 = pd.date_range("2020-01-06", "2020-04-03", freq="MS")
```

```
In [235]: dates_lst_1
```

```
Out[235]: DatetimeIndex(['2020-02-01', '2020-03-01', '2020-04-01'],
                         freq='MS')
```

```
In [236]: dates_lst_2 = pd.date_range("2020-01-01", "2020-04-01", freq="MS")
```

```
In [237]: dates_lst_2
```

```
Out[237]: DatetimeIndex(['2020-01-01', '2020-02-01', '2020-03-01', '2020-04-01'],
                         freq='MS')
```

We can see in the above example `date_range()` and `bdate_range()` will only return the valid timestamps between the `start_date` and `end_date`. If these are not valid timestamps for the given frequency it will roll to the next value for `start_date` (respectively previous for the `end_date`)

Combining aliases

As we have seen previously, the alias and the offset instance are fungible in most functions:

```
In [238]: pd.date_range(start, periods=5, freq="B")
```

```
Out[238]:
```

```
DatetimeIndex(['2011-01-03', '2011-01-04', '2011-01-05', '2011-01-06',
                '2011-01-07'],
               dtype='datetime64[ns]', freq='B')
```

```
In [239]: pd.date_range(start, periods=5, freq=pd.offsets.BDay())
```

```
Out[239]:
```

```
DatetimeIndex(['2011-01-03', '2011-01-04', '2011-01-05', '2011-01-06',
                '2011-01-07'],
               dtype='datetime64[ns]', freq='B')
```

You can combine together day and intraday offsets:

```
In [240]: pd.date_range(start, periods=10, freq="2h20min")
```

```
Out[240]:
```

```
DatetimeIndex(['2011-01-01 00:00:00', '2011-01-01 02:20:00',
                '2011-01-01 04:40:00', '2011-01-01 07:00:00',
                '2011-01-01 09:20:00', '2011-01-01 11:40:00',
                '2011-01-01 14:00:00', '2011-01-01 16:20:00',
                '2011-01-01 18:40:00', '2011-01-01 21:00:00'],
               dtype='datetime64[ns]', freq='140T')
```

```
In [241]: pd.date_range(start, periods=10, freq="1D10U")
```

```
Out[241]:
```

```
DatetimeIndex(['2011-01-01 00:00:00', '2011-01-02 00:00:00.000010',
                '2011-01-03 00:00:00.000020', '2011-01-04 00:00:00.000030',
                '2011-01-05 00:00:00.000040', '2011-01-06 00:00:00.000050',
                '2011-01-07 00:00:00.000060', '2011-01-08 00:00:00.000070',
                '2011-01-09 00:00:00.000080', '2011-01-10 00:00:00.000090'],
               dtype='datetime64[ns]', freq='86400000010U')
```

Anchored offsets

For some frequencies you can specify an anchoring suffix:

Alias	Description
W-SUN	weekly frequency (Sundays). Same as 'W'
W-MON	weekly frequency (Mondays)
W-TUE	weekly frequency (Tuesdays)
W-WED	weekly frequency (Wednesdays)
W-THU	weekly frequency (Thursdays)
W-FRI	weekly frequency (Fridays)
W-SAT	weekly frequency (Saturdays)
(B)Q(S)-DEC	quarterly frequency, year ends in December. Same as 'Q'
(B)Q(S)-JAN	quarterly frequency, year ends in January
(B)Q(S)-FEB	quarterly frequency, year ends in February
(B)Q(S)-MAR	quarterly frequency, year ends in March
(B)Q(S)-APR	quarterly frequency, year ends in April
(B)Q(S)-MAY	quarterly frequency, year ends in May
(B)Q(S)-JUN	quarterly frequency, year ends in June
(B)Q(S)-JUL	quarterly frequency, year ends in July
(B)Q(S)-AUG	quarterly frequency, year ends in August
(B)Q(S)-SEP	quarterly frequency, year ends in September
(B)Q(S)-OCT	quarterly frequency, year ends in October
(B)Q(S)-NOV	quarterly frequency, year ends in November
(B)A(S)-DEC	annual frequency, anchored end of December. Same as 'A'
(B)A(S)-JAN	annual frequency, anchored end of January
(B)A(S)-FEB	annual frequency, anchored end of February
(B)A(S)-MAR	annual frequency, anchored end of March
(B)A(S)-APR	annual frequency, anchored end of April
(B)A(S)-MAY	annual frequency, anchored end of May
(B)A(S)-JUN	annual frequency, anchored end of June
(B)A(S)-JUL	annual frequency, anchored end of July

continues on next page

Table 4 – continued from previous page

Alias	Description
(B)A(S)-AUG	annual frequency, anchored end of August
(B)A(S)-SEP	annual frequency, anchored end of September
(B)A(S)-OCT	annual frequency, anchored end of October
(B)A(S)-NOV	annual frequency, anchored end of November

These can be used as arguments to `date_range`, `bdate_range`, constructors for `DatetimeIndex`, as well as various other timeseries-related functions in pandas.

Anchored offset semantics

For those offsets that are anchored to the start or end of specific frequency (`MonthEnd`, `MonthBegin`, `WeekEnd`, etc), the following rules apply to rolling forward and backwards.

When n is not 0, if the given date is not on an anchor point, it snapped to the next(previous) anchor point, and moved $|n| - 1$ additional steps forwards or backwards.

```
In [242]: pd.Timestamp("2014-01-02") + pd.offsets.MonthBegin(n=1)
Out[242]: Timestamp('2014-02-01 00:00:00')
```

```
In [243]: pd.Timestamp("2014-01-02") + pd.offsets.MonthEnd(n=1)
Out[243]: Timestamp('2014-01-31 00:00:00')
```

```
In [244]: pd.Timestamp("2014-01-02") - pd.offsets.MonthBegin(n=1)
Out[244]: Timestamp('2014-01-01 00:00:00')
```

```
In [245]: pd.Timestamp("2014-01-02") - pd.offsets.MonthEnd(n=1)
Out[245]: Timestamp('2013-12-31 00:00:00')
```

```
In [246]: pd.Timestamp("2014-01-02") + pd.offsets.MonthBegin(n=4)
Out[246]: Timestamp('2014-05-01 00:00:00')
```

```
In [247]: pd.Timestamp("2014-01-02") - pd.offsets.MonthBegin(n=4)
Out[247]: Timestamp('2013-10-01 00:00:00')
```

If the given date *is* on an anchor point, it is moved $|n|$ points forwards or backwards.

```
In [248]: pd.Timestamp("2014-01-01") + pd.offsets.MonthBegin(n=1)
Out[248]: Timestamp('2014-02-01 00:00:00')
```

```
In [249]: pd.Timestamp("2014-01-31") + pd.offsets.MonthEnd(n=1)
Out[249]: Timestamp('2014-02-28 00:00:00')
```

```
In [250]: pd.Timestamp("2014-01-01") - pd.offsets.MonthBegin(n=1)
Out[250]: Timestamp('2013-12-01 00:00:00')
```

```
In [251]: pd.Timestamp("2014-01-31") - pd.offsets.MonthEnd(n=1)
Out[251]: Timestamp('2013-12-31 00:00:00')
```

(continues on next page)

(continued from previous page)

```
In [252]: pd.Timestamp("2014-01-01") + pd.offsets.MonthBegin(n=4)
Out[252]: Timestamp('2014-05-01 00:00:00')
```

```
In [253]: pd.Timestamp("2014-01-31") - pd.offsets.MonthBegin(n=4)
Out[253]: Timestamp('2013-10-01 00:00:00')
```

For the case when n=0, the date is not moved if on an anchor point, otherwise it is rolled forward to the next anchor point.

```
In [254]: pd.Timestamp("2014-01-02") + pd.offsets.MonthBegin(n=0)
Out[254]: Timestamp('2014-02-01 00:00:00')
```

```
In [255]: pd.Timestamp("2014-01-02") + pd.offsets.MonthEnd(n=0)
Out[255]: Timestamp('2014-01-31 00:00:00')
```

```
In [256]: pd.Timestamp("2014-01-01") + pd.offsets.MonthBegin(n=0)
Out[256]: Timestamp('2014-01-01 00:00:00')
```

```
In [257]: pd.Timestamp("2014-01-31") + pd.offsets.MonthEnd(n=0)
Out[257]: Timestamp('2014-01-31 00:00:00')
```

Holidays / holiday calendars

Holidays and calendars provide a simple way to define holiday rules to be used with `CustomBusinessDay` or in other analysis that requires a predefined set of holidays. The `AbstractHolidayCalendar` class provides all the necessary methods to return a list of holidays and only `rules` need to be defined in a specific holiday calendar class. Furthermore, the `start_date` and `end_date` class attributes determine over what date range holidays are generated. These should be overwritten on the `AbstractHolidayCalendar` class to have the range apply to all calendar subclasses. `USFederalHolidayCalendar` is the only calendar that exists and primarily serves as an example for developing other calendars.

For holidays that occur on fixed dates (e.g., US Memorial Day or July 4th) an observance rule determines when that holiday is observed if it falls on a weekend or some other non-observed day. Defined observance rules are:

Rule	Description
nearest_workday	move Saturday to Friday and Sunday to Monday
sun-day_to_monday	move Sunday to following Monday
next_monday_or_tuesday	Saturday to Monday and Sunday/Monday to Tuesday
previous_friday	move Saturday and Sunday to previous Friday”
next_monday	move Saturday and Sunday to following Monday

An example of how holidays and holiday calendars are defined:

```
In [258]: from pandas.tseries.holiday import (
    ....:     Holiday,
    ....:     USMemorialDay,
    ....:     AbstractHolidayCalendar,
    ....:     nearest_workday,
    ....:     MO,
```

(continues on next page)

(continued from previous page)

```

....: )
....:

In [259]: class ExampleCalendar(AbstractHolidayCalendar):
....:     rules = [
....:         USMemorialDay,
....:         Holiday("July 4th", month=7, day=4, observance=nearest_workday),
....:         Holiday(
....:             "Columbus Day",
....:             month=10,
....:             day=1,
....:             offset=pd.DateOffset(weekday=MO(2)),
....:         ),
....:     ]
....:

In [260]: cal = ExampleCalendar()

In [261]: cal.holidays(datetime.datetime(2012, 1, 1), datetime.datetime(2012, 12, 31))
Out[261]: DatetimeIndex(['2012-05-28', '2012-07-04', '2012-10-08'], dtype='datetime64[ns]'.
˓→', freq=None)

```

hint `weekday=MO(2)` is same as `2 * Week(weekday=2)`

Using this calendar, creating an index or doing offset arithmetic skips weekends and holidays (i.e., Memorial Day/July 4th). For example, the below defines a custom business day offset using the `ExampleCalendar`. Like any other offset, it can be used to create a `DatetimeIndex` or added to `datetime` or `Timestamp` objects.

```

In [262]: pd.date_range(
....:     start="7/1/2012", end="7/10/2012", freq=pd.offsets.CDay(calendar=cal)
....: ).to_pydatetime()
....:

Out[262]:
array([datetime.datetime(2012, 7, 2, 0, 0),
       datetime.datetime(2012, 7, 3, 0, 0),
       datetime.datetime(2012, 7, 5, 0, 0),
       datetime.datetime(2012, 7, 6, 0, 0),
       datetime.datetime(2012, 7, 9, 0, 0),
       datetime.datetime(2012, 7, 10, 0, 0)], dtype=object)

In [263]: offset = pd.offsets.CustomBusinessDay(calendar=cal)

In [264]: datetime.datetime(2012, 5, 25) + offset
Out[264]: Timestamp('2012-05-29 00:00:00')

In [265]: datetime.datetime(2012, 7, 3) + offset
Out[265]: Timestamp('2012-07-05 00:00:00')

In [266]: datetime.datetime(2012, 7, 3) + 2 * offset
Out[266]: Timestamp('2012-07-06 00:00:00')

In [267]: datetime.datetime(2012, 7, 6) + offset
Out[267]: Timestamp('2012-07-09 00:00:00')

```

Ranges are defined by the `start_date` and `end_date` class attributes of `AbstractHolidayCalendar`. The defaults are shown below.

```
In [268]: AbstractHolidayCalendar.start_date
Out[268]: Timestamp('1970-01-01 00:00:00')
```

```
In [269]: AbstractHolidayCalendar.end_date
Out[269]: Timestamp('2200-12-31 00:00:00')
```

These dates can be overwritten by setting the attributes as datetime/Timestamp/string.

```
In [270]: AbstractHolidayCalendar.start_date = datetime.datetime(2012, 1, 1)
```

```
In [271]: AbstractHolidayCalendar.end_date = datetime.datetime(2012, 12, 31)
```

```
In [272]: cal.holidays()
Out[272]: DatetimeIndex(['2012-05-28', '2012-07-04', '2012-10-08'], dtype='datetime64[ns']
˓→', freq=None)
```

Every calendar class is accessible by name using the `get_calendar` function which returns a holiday class instance. Any imported calendar class will automatically be available by this function. Also, `HolidayCalendarFactory` provides an easy interface to create calendars that are combinations of calendars or calendars with additional rules.

```
In [273]: from pandas.tseries.holiday import get_calendar, HolidayCalendarFactory,
˓→USLaborDay
```

```
In [274]: cal = get_calendar("ExampleCalendar")
```

```
In [275]: cal.rules
```

```
Out[275]:
[Holiday: Memorial Day (month=5, day=31, offset=<DateOffset: weekday=M0(-1)>),
Holiday: July 4th (month=7, day=4, observance=<function nearest_workday at_˓→0x7f54ed1375e0>),
Holiday: Columbus Day (month=10, day=1, offset=<DateOffset: weekday=M0(+2)>)]
```

```
In [276]: new_cal = HolidayCalendarFactory("NewExampleCalendar", cal, USLaborDay)
```

```
In [277]: new_cal.rules
```

```
Out[277]:
[Holiday: Labor Day (month=9, day=1, offset=<DateOffset: weekday=M0(+1)>),
Holiday: Memorial Day (month=5, day=31, offset=<DateOffset: weekday=M0(-1)>),
Holiday: July 4th (month=7, day=4, observance=<function nearest_workday at_˓→0x7f54ed1375e0>),
Holiday: Columbus Day (month=10, day=1, offset=<DateOffset: weekday=M0(+2)>)]
```

2.20.9 Time series-related instance methods

Shifting / lagging

One may want to *shift* or *lag* the values in a time series back and forward in time. The method for this is `shift()`, which is available on all of the pandas objects.

```
In [278]: ts = pd.Series(range(len(rng))), index=rng)
```

```
In [279]: ts = ts[:5]
```

```
In [280]: ts.shift(1)
```

```
Out[280]:
```

```
2012-01-01    NaN
2012-01-02    0.0
2012-01-03    1.0
Freq: D, dtype: float64
```

The `shift` method accepts an `freq` argument which can accept a `DateOffset` class or other `timedelta`-like object or also an *offset alias*.

When `freq` is specified, `shift` method changes all the dates in the index rather than changing the alignment of the data and the index:

```
In [281]: ts.shift(5, freq="D")
```

```
Out[281]:
```

```
2012-01-06    0
2012-01-07    1
2012-01-08    2
Freq: D, dtype: int64
```

```
In [282]: ts.shift(5, freq=pd.offsets.BDay())
```

```
Out[282]:
```

```
2012-01-06    0
2012-01-09    1
2012-01-10    2
dtype: int64
```

```
In [283]: ts.shift(5, freq="BM")
```

```
Out[283]:
```

```
2012-05-31    0
2012-05-31    1
2012-05-31    2
dtype: int64
```

Note that with when `freq` is specified, the leading entry is no longer `NaN` because the data is not being realigned.

Frequency conversion

The primary function for changing frequencies is the `asfreq()` method. For a DatetimeIndex, this is basically just a thin, but convenient wrapper around `reindex()` which generates a date_range and calls `reindex`.

```
In [284]: dr = pd.date_range("1/1/2010", periods=3, freq=3 * pd.offsets.BDay())
```

```
In [285]: ts = pd.Series(np.random.randn(3), index=dr)
```

```
In [286]: ts
```

```
Out[286]:
```

2010-01-01	1.494522
2010-01-06	-0.778425
2010-01-11	-0.253355

Freq: B, dtype: float64

```
In [287]: ts.asfreq(pd.offsets.BDay())
```

```
Out[287]:
```

2010-01-01	1.494522
2010-01-04	NaN
2010-01-05	NaN
2010-01-06	-0.778425
2010-01-07	NaN
2010-01-08	NaN
2010-01-11	-0.253355

Freq: B, dtype: float64

`asfreq` provides a further convenience so you can specify an interpolation method for any gaps that may appear after the frequency conversion.

```
In [288]: ts.asfreq(pd.offsets.BDay(), method="pad")
```

```
Out[288]:
```

2010-01-01	1.494522
2010-01-04	1.494522
2010-01-05	1.494522
2010-01-06	-0.778425
2010-01-07	-0.778425
2010-01-08	-0.778425
2010-01-11	-0.253355

Freq: B, dtype: float64

Filling forward / backward

Related to `asfreq` and `reindex` is `fillna()`, which is documented in the [missing data section](#).

Converting to Python datetimes

`DatetimeIndex` can be converted to an array of Python native `datetime.datetime` objects using the `to_pydatetime` method.

2.20.10 Resampling

pandas has a simple, powerful, and efficient functionality for performing resampling operations during frequency conversion (e.g., converting secondly data into 5-minute data). This is extremely common in, but not limited to, financial applications.

`resample()` is a time-based groupby, followed by a reduction method on each of its groups. See some [cookbook examples](#) for some advanced strategies.

The `resample()` method can be used directly from `DataFrameGroupBy` objects, see the [groupby docs](#).

Basics

```
In [289]: rng = pd.date_range("1/1/2012", periods=100, freq="S")
In [290]: ts = pd.Series(np.random.randint(0, 500, len(rng)), index=rng)
In [291]: ts.resample("5Min").sum()
Out[291]:
2012-01-01    25103
Freq: 5T, dtype: int64
```

The `resample` function is very flexible and allows you to specify many different parameters to control the frequency conversion and resampling operation.

Any function available via `dispatching` is available as a method of the returned object, including `sum`, `mean`, `std`, `sem`, `max`, `min`, `median`, `first`, `last`, `ohlc`:

```
In [292]: ts.resample("5Min").mean()
Out[292]:
2012-01-01    251.03
Freq: 5T, dtype: float64

In [293]: ts.resample("5Min").ohlc()
Out[293]:
      open  high  low  close
2012-01-01    308   460     9    205

In [294]: ts.resample("5Min").max()
Out[294]:
2012-01-01    460
Freq: 5T, dtype: int64
```

For down sampling, `closed` can be set to ‘left’ or ‘right’ to specify which end of the interval is closed:

```
In [295]: ts.resample("5Min", closed="right").mean()
```

```
Out[295]:
```

```
2011-12-31 23:55:00    308.000000
2012-01-01 00:00:00    250.454545
Freq: 5T, dtype: float64
```

```
In [296]: ts.resample("5Min", closed="left").mean()
```

```
Out[296]:
```

```
2012-01-01    251.03
Freq: 5T, dtype: float64
```

Parameters like `label` are used to manipulate the resulting labels. `label` specifies whether the result is labeled with the beginning or the end of the interval.

```
In [297]: ts.resample("5Min").mean() # by default label='left'
```

```
Out[297]:
```

```
2012-01-01    251.03
Freq: 5T, dtype: float64
```

```
In [298]: ts.resample("5Min", label="left").mean()
```

```
Out[298]:
```

```
2012-01-01    251.03
Freq: 5T, dtype: float64
```

Warning: The default values for `label` and `closed` is '`left`' for all frequency offsets except for 'M', 'A', 'Q', 'BM', 'BA', 'BQ', and 'W' which all have a default of 'right'.

This might unintendedly lead to looking ahead, where the value for a later time is pulled back to a previous time as in the following example with the `BusinessDay` frequency:

```
In [299]: s = pd.date_range("2000-01-01", "2000-01-05").to_series()
```

```
In [300]: s.iloc[2] = pd.NaT
```

```
In [301]: s.dt.day_name()
```

```
Out[301]:
```

```
2000-01-01    Saturday
2000-01-02    Sunday
2000-01-03    NaN
2000-01-04    Tuesday
2000-01-05    Wednesday
Freq: D, dtype: object
```

```
# default: label='left', closed='left'
```

```
In [302]: s.resample("B").last().dt.day_name()
```

```
Out[302]:
```

```
1999-12-31    Sunday
2000-01-03    NaN
2000-01-04    Tuesday
2000-01-05    Wednesday
Freq: B, dtype: object
```

Notice how the value for Sunday got pulled back to the previous Friday. To get the behavior where the value for

Sunday is pushed to Monday, use instead

```
In [303]: s.resample("B", label="right", closed="right").last().dt.day_name()
```

```
Out[303]:
```

```
2000-01-03    Sunday
2000-01-04    Tuesday
2000-01-05   Wednesday
Freq: B, dtype: object
```

The `axis` parameter can be set to 0 or 1 and allows you to resample the specified axis for a `DataFrame`.

`kind` can be set to ‘timestamp’ or ‘period’ to convert the resulting index to/from timestamp and time span representations. By default `resample` retains the input representation.

`convention` can be set to ‘start’ or ‘end’ when resampling period data (detail below). It specifies how low frequency periods are converted to higher frequency periods.

Upsampling

For upsampling, you can specify a way to upsample and the `limit` parameter to interpolate over the gaps that are created:

```
# from secondly to every 250 milliseconds
```

```
In [304]: ts[:2].resample("250L").asfreq()
```

```
Out[304]:
```

```
2012-01-01 00:00:00.000    308.0
2012-01-01 00:00:00.250      NaN
2012-01-01 00:00:00.500      NaN
2012-01-01 00:00:00.750      NaN
2012-01-01 00:00:01.000    204.0
Freq: 250L, dtype: float64
```

```
In [305]: ts[:2].resample("250L").ffill()
```

```
Out[305]:
```

```
2012-01-01 00:00:00.000    308
2012-01-01 00:00:00.250    308
2012-01-01 00:00:00.500    308
2012-01-01 00:00:00.750    308
2012-01-01 00:00:01.000    204
Freq: 250L, dtype: int64
```

```
In [306]: ts[:2].resample("250L").ffill(limit=2)
```

```
Out[306]:
```

```
2012-01-01 00:00:00.000    308.0
2012-01-01 00:00:00.250    308.0
2012-01-01 00:00:00.500    308.0
2012-01-01 00:00:00.750      NaN
2012-01-01 00:00:01.000    204.0
Freq: 250L, dtype: float64
```

Sparse resampling

Sparse timeseries are the ones where you have a lot fewer points relative to the amount of time you are looking to resample. Naively upsampling a sparse series can potentially generate lots of intermediate values. When you don't want to use a method to fill these values, e.g. `fill_method` is `None`, then intermediate values will be filled with `NaN`.

Since `resample` is a time-based groupby, the following is a method to efficiently resample only the groups that are not all `NaN`.

```
In [307]: rng = pd.date_range("2014-1-1", periods=100, freq="D") + pd.Timedelta("1s")
```

```
In [308]: ts = pd.Series(range(100), index=rng)
```

If we want to resample to the full range of the series:

```
In [309]: ts.resample("3T").sum()
Out[309]:
2014-01-01 00:00:00      0
2014-01-01 00:03:00      0
2014-01-01 00:06:00      0
2014-01-01 00:09:00      0
2014-01-01 00:12:00      0
...
2014-04-09 23:48:00      0
2014-04-09 23:51:00      0
2014-04-09 23:54:00      0
2014-04-09 23:57:00      0
2014-04-10 00:00:00     99
Freq: 3T, Length: 47521, dtype: int64
```

We can instead only resample those groups where we have points as follows:

```
In [310]: from functools import partial
```

```
In [311]: from pandas.tseries.frequencies import to_offset
```

```
In [312]: def round(t, freq):
....:     freq = to_offset(freq)
....:     return pd.Timestamp((t.value // freq.delta.value) * freq.delta.value)
....:
```

```
In [313]: ts.groupby(partial(round, freq="3T")).sum()
```

```
Out[313]:
2014-01-01      0
2014-01-02      1
2014-01-03      2
2014-01-04      3
2014-01-05      4
...
2014-04-06     95
2014-04-07     96
2014-04-08     97
2014-04-09     98
2014-04-10     99
Length: 100, dtype: int64
```

Aggregation

Similar to the [aggregating API](#), [groupby API](#), and the [window API](#), a Resampler can be selectively resampled.

Resampling a DataFrame, the default will be to act on all columns with the same function.

```
In [314]: df = pd.DataFrame(
.....:     np.random.randn(1000, 3),
.....:     index=pd.date_range("1/1/2012", freq="S", periods=1000),
.....:     columns=["A", "B", "C"],
.....: )
.....:

In [315]: r = df.resample("3T")

In [316]: r.mean()
Out[316]:
          A         B         C
2012-01-01 00:00:00 -0.033823 -0.121514 -0.081447
2012-01-01 00:03:00  0.056909  0.146731 -0.024320
2012-01-01 00:06:00 -0.058837  0.047046 -0.052021
2012-01-01 00:09:00  0.063123 -0.026158 -0.066533
2012-01-01 00:12:00  0.186340 -0.003144  0.074752
2012-01-01 00:15:00 -0.085954 -0.016287 -0.050046
```

We can select a specific column or columns using standard getitem.

```
In [317]: r["A"].mean()
Out[317]:
2012-01-01 00:00:00   -0.033823
2012-01-01 00:03:00    0.056909
2012-01-01 00:06:00   -0.058837
2012-01-01 00:09:00    0.063123
2012-01-01 00:12:00    0.186340
2012-01-01 00:15:00   -0.085954
Freq: 3T, Name: A, dtype: float64

In [318]: r[["A", "B"]].mean()
Out[318]:
          A         B
2012-01-01 00:00:00 -0.033823 -0.121514
2012-01-01 00:03:00  0.056909  0.146731
2012-01-01 00:06:00 -0.058837  0.047046
2012-01-01 00:09:00  0.063123 -0.026158
2012-01-01 00:12:00  0.186340 -0.003144
2012-01-01 00:15:00 -0.085954 -0.016287
```

You can pass a list or dict of functions to do aggregation with, outputting a DataFrame:

```
In [319]: r["A"].agg([np.sum, np.mean, np.std])
Out[319]:
           sum      mean       std
2012-01-01 00:00:00 -6.088060 -0.033823  1.043263
2012-01-01 00:03:00 10.243678  0.056909  1.058534
```

(continues on next page)

(continued from previous page)

2012-01-01 00:06:00 -10.590584 -0.058837 0.949264
2012-01-01 00:09:00 11.362228 0.063123 1.028096
2012-01-01 00:12:00 33.541257 0.186340 0.884586
2012-01-01 00:15:00 -8.595393 -0.085954 1.035476

On a resampled DataFrame, you can pass a list of functions to apply to each column, which produces an aggregated result with a hierarchical index:

In [320]: `r.agg([np.sum, np.mean])`

Out[320]:

	A		B		C	
	sum	mean	sum	mean	sum	mean
2012-01-01 00:00:00	-6.088060	-0.033823	-21.872530	-0.121514	-14.660515	-0.081447
2012-01-01 00:03:00	10.243678	0.056909	26.411633	0.146731	-4.377642	-0.024320
2012-01-01 00:06:00	-10.590584	-0.058837	8.468289	0.047046	-9.363825	-0.052021
2012-01-01 00:09:00	11.362228	0.063123	-4.708526	-0.026158	-11.975895	-0.066533
2012-01-01 00:12:00	33.541257	0.186340	-0.565895	-0.003144	13.455299	0.074752
2012-01-01 00:15:00	-8.595393	-0.085954	-1.628689	-0.016287	-5.004580	-0.050046

By passing a dict to aggregate you can apply a different aggregation to the columns of a DataFrame:

In [321]: `r.agg({"A": np.sum, "B": lambda x: np.std(x, ddof=1)})`

Out[321]:

	A	B
2012-01-01 00:00:00	-6.088060	1.001294
2012-01-01 00:03:00	10.243678	1.074597
2012-01-01 00:06:00	-10.590584	0.987309
2012-01-01 00:09:00	11.362228	0.944953
2012-01-01 00:12:00	33.541257	1.095025
2012-01-01 00:15:00	-8.595393	1.035312

The function names can also be strings. In order for a string to be valid it must be implemented on the resampled object:

In [322]: `r.agg({"A": "sum", "B": "std"})`

Out[322]:

	A	B
2012-01-01 00:00:00	-6.088060	1.001294
2012-01-01 00:03:00	10.243678	1.074597
2012-01-01 00:06:00	-10.590584	0.987309
2012-01-01 00:09:00	11.362228	0.944953
2012-01-01 00:12:00	33.541257	1.095025
2012-01-01 00:15:00	-8.595393	1.035312

Furthermore, you can also specify multiple aggregation functions for each column separately.

In [323]: `r.agg({"A": ["sum", "std"], "B": ["mean", "std"]})`

Out[323]:

	A		B	
	sum	std	mean	std
2012-01-01 00:00:00	-6.088060	1.043263	-0.121514	1.001294
2012-01-01 00:03:00	10.243678	1.058534	0.146731	1.074597
2012-01-01 00:06:00	-10.590584	0.949264	0.047046	0.987309
2012-01-01 00:09:00	11.362228	1.028096	-0.026158	0.944953

(continues on next page)

(continued from previous page)

2012-01-01 00:12:00	33.541257	0.884586	-0.003144	1.095025
2012-01-01 00:15:00	-8.595393	1.035476	-0.016287	1.035312

If a DataFrame does not have a datetimelike index, but instead you want to resample based on datetimelike column in the frame, it can be passed to the `on` keyword.

```
In [324]: df = pd.DataFrame(
    ....:     {"date": pd.date_range("2015-01-01", freq="W", periods=5), "a": np.
    ↪arange(5)},
    ....:     index=pd.MultiIndex.from_arrays(
    ....:         [[1, 2, 3, 4, 5], pd.date_range("2015-01-01", freq="W", periods=5)],
    ....:         names=["v", "d"],
    ....:     ),
    ....: )
    ....:

In [325]: df
Out[325]:
          date   a
v d
1 2015-01-04 2015-01-04  0
2 2015-01-11 2015-01-11  1
3 2015-01-18 2015-01-18  2
4 2015-01-25 2015-01-25  3
5 2015-02-01 2015-02-01  4

In [326]: df.resample("M", on="date").sum()
Out[326]:
          a
date
2015-01-31  6
2015-02-28  4
```

Similarly, if you instead want to resample by a datetimelike level of MultiIndex, its name or location can be passed to the `level` keyword.

```
In [327]: df.resample("M", level="d").sum()
Out[327]:
          a
d
2015-01-31  6
2015-02-28  4
```

Iterating through groups

With the Resampler object in hand, iterating through the grouped data is very natural and functions similarly to `itertools.groupby()`:

```
In [328]: small = pd.Series(
    ....:     range(6),
    ....:     index=pd.to_datetime(
    ....:         [
    ....:             "2017-01-01T00:00:00",
    ....:             "2017-01-01T00:30:00",
    ....:             "2017-01-01T00:31:00",
    ....:             "2017-01-01T01:00:00",
    ....:             "2017-01-01T03:00:00",
    ....:             "2017-01-01T03:05:00",
    ....:         ]
    ....:     ),
    ....: )
....:
```

```
In [329]: resampled = small.resample("H")
```

```
In [330]: for name, group in resampled:
    ....:     print("Group: ", name)
    ....:     print("-" * 27)
    ....:     print(group, end="\n\n")
....:
```

```
Group: 2017-01-01 00:00:00
-----
2017-01-01 00:00:00      0
2017-01-01 00:30:00      1
2017-01-01 00:31:00      2
dtype: int64

Group: 2017-01-01 01:00:00
-----
2017-01-01 01:00:00      3
dtype: int64

Group: 2017-01-01 02:00:00
-----
Series([], dtype: int64)

Group: 2017-01-01 03:00:00
-----
2017-01-01 03:00:00      4
2017-01-01 03:05:00      5
dtype: int64
```

See [Iterating through groups](#) or `Resampler.__iter__` for more.

Use origin or offset to adjust the start of the bins

New in version 1.1.0.

The bins of the grouping are adjusted based on the beginning of the day of the time series starting point. This works well with frequencies that are multiples of a day (like `30D`) or that divide a day evenly (like `90s` or `1min`). This can create inconsistencies with some frequencies that do not meet this criteria. To change this behavior you can specify a fixed Timestamp with the argument `origin`.

For example:

```
In [331]: start, end = "2000-10-01 23:30:00", "2000-10-02 00:30:00"
In [332]: middle = "2000-10-02 00:00:00"
In [333]: rng = pd.date_range(start, end, freq="7min")
In [334]: ts = pd.Series(np.arange(len(rng)) * 3, index=rng)
In [335]: ts
Out[335]:
2000-10-01 23:30:00    0
2000-10-01 23:37:00    3
2000-10-01 23:44:00    6
2000-10-01 23:51:00    9
2000-10-01 23:58:00   12
2000-10-02 00:05:00   15
2000-10-02 00:12:00   18
2000-10-02 00:19:00   21
2000-10-02 00:26:00   24
Freq: 7T, dtype: int64
```

Here we can see that, when using `origin` with its default value ('`start_day`'), the result after '`2000-10-02 00:00:00`' are not identical depending on the start of time series:

```
In [336]: ts.resample("17min", origin="start_day").sum()
Out[336]:
2000-10-01 23:14:00    0
2000-10-01 23:31:00    9
2000-10-01 23:48:00   21
2000-10-02 00:05:00   54
2000-10-02 00:22:00   24
Freq: 17T, dtype: int64

In [337]: ts[middle:end].resample("17min", origin="start_day").sum()
Out[337]:
2000-10-02 00:00:00    33
2000-10-02 00:17:00    45
Freq: 17T, dtype: int64
```

Here we can see that, when setting `origin` to '`epoch`', the result after '`2000-10-02 00:00:00`' are identical depending on the start of time series:

```
In [338]: ts.resample("17min", origin="epoch").sum()
Out[338]:
```

(continues on next page)

(continued from previous page)

```
2000-10-01 23:18:00      0
2000-10-01 23:35:00     18
2000-10-01 23:52:00     27
2000-10-02 00:09:00     39
2000-10-02 00:26:00     24
Freq: 17T, dtype: int64
```

In [339]: ts[middle:end].resample("17min", origin="epoch").sum()

Out[339]:

```
2000-10-01 23:52:00     15
2000-10-02 00:09:00     39
2000-10-02 00:26:00     24
Freq: 17T, dtype: int64
```

If needed you can use a custom timestamp for `origin`:

In [340]: ts.resample("17min", origin="2001-01-01").sum()

Out[340]:

```
2000-10-01 23:30:00      9
2000-10-01 23:47:00     21
2000-10-02 00:04:00     54
2000-10-02 00:21:00     24
Freq: 17T, dtype: int64
```

In [341]: ts[middle:end].resample("17min", origin=pd.Timestamp("2001-01-01")).sum()

Out[341]:

```
2000-10-02 00:04:00     54
2000-10-02 00:21:00     24
Freq: 17T, dtype: int64
```

If needed you can just adjust the bins with an `offset` Timedelta that would be added to the default `origin`. Those two examples are equivalent for this time series:

In [342]: ts.resample("17min", origin="start").sum()

Out[342]:

```
2000-10-01 23:30:00      9
2000-10-01 23:47:00     21
2000-10-02 00:04:00     54
2000-10-02 00:21:00     24
Freq: 17T, dtype: int64
```

In [343]: ts.resample("17min", offset="23h30min").sum()

Out[343]:

```
2000-10-01 23:30:00      9
2000-10-01 23:47:00     21
2000-10-02 00:04:00     54
2000-10-02 00:21:00     24
Freq: 17T, dtype: int64
```

Note the use of 'start' for `origin` on the last example. In that case, `origin` will be set to the first value of the timeseries.

Backward resample

New in version 1.3.0.

Instead of adjusting the beginning of bins, sometimes we need to fix the end of the bins to make a backward resample with a given freq. The backward resample sets closed to 'right' by default since the last value should be considered as the edge point for the last bin.

We can set origin to 'end'. The value for a specific Timestamp index stands for the resample result from the current Timestamp minus freq to the current Timestamp with a right close.

```
In [344]: ts.resample('17min', origin='end').sum()
Out[344]:
2000-10-01 23:35:00      0
2000-10-01 23:52:00     18
2000-10-02 00:09:00     27
2000-10-02 00:26:00     63
Freq: 17T, dtype: int64
```

Besides, in contrast with the 'start_day' option, end_day is supported. This will set the origin as the ceiling midnight of the largest Timestamp.

```
In [345]: ts.resample('17min', origin='end_day').sum()
Out[345]:
2000-10-01 23:38:00      3
2000-10-01 23:55:00     15
2000-10-02 00:12:00     45
2000-10-02 00:29:00     45
Freq: 17T, dtype: int64
```

The above result uses 2000-10-02 00:29:00 as the last bin's right edge since the following computation.

```
In [346]: ceil_mid = rng.max().ceil('D')
In [347]: freq = pd.offsets.Minute(17)
In [348]: bin_res = ceil_mid - freq * ((ceil_mid - rng.max()) // freq)
In [349]: bin_res
Out[349]: Timestamp('2000-10-02 00:29:00')
```

2.20.11 Time span representation

Regular intervals of time are represented by Period objects in pandas while sequences of Period objects are collected in a PeriodIndex, which can be created with the convenience function `period_range`.

Period

A Period represents a span of time (e.g., a day, a month, a quarter, etc). You can specify the span via `freq` keyword using a frequency alias like below. Because `freq` represents a span of Period, it cannot be negative like “-3D”.

```
In [350]: pd.Period("2012", freq="A-DEC")
Out[350]: Period('2012', 'A-DEC')

In [351]: pd.Period("2012-1-1", freq="D")
Out[351]: Period('2012-01-01', 'D')

In [352]: pd.Period("2012-1-1 19:00", freq="H")
Out[352]: Period('2012-01-01 19:00', 'H')

In [353]: pd.Period("2012-1-1 19:00", freq="5H")
Out[353]: Period('2012-01-01 19:00', '5H')
```

Adding and subtracting integers from periods shifts the period by its own frequency. Arithmetic is not allowed between Period with different `freq` (span).

```
In [354]: p = pd.Period("2012", freq="A-DEC")

In [355]: p + 1
Out[355]: Period('2013', 'A-DEC')

In [356]: p - 3
Out[356]: Period('2009', 'A-DEC')

In [357]: p = pd.Period("2012-01", freq="2M")

In [358]: p + 2
Out[358]: Period('2012-05', '2M')

In [359]: p - 1
Out[359]: Period('2011-11', '2M')

In [360]: p == pd.Period("2012-01", freq="3M")
Out[360]: False
```

If Period `freq` is daily or higher (D, H, T, S, L, U, N), `offsets` and `timedelta-like` can be added if the result can have the same `freq`. Otherwise, `ValueError` will be raised.

```
In [361]: p = pd.Period("2014-07-01 09:00", freq="H")

In [362]: p + pd.offsets.Hour(2)
Out[362]: Period('2014-07-01 11:00', 'H')

In [363]: p + datetime.timedelta(minutes=120)
```

(continues on next page)

(continued from previous page)

```
Out[363]: Period('2014-07-01 11:00', 'H')
```

```
In [364]: p + np.timedelta64(7200, "s")
```

```
Out[364]: Period('2014-07-01 11:00', 'H')
```

```
In [1]: p + pd.offsets.Minute(5)
```

```
Traceback
```

```
...
```

```
ValueError: Input has different freq from Period(freq=H)
```

If Period has other frequencies, only the same offsets can be added. Otherwise, ValueError will be raised.

```
In [365]: p = pd.Period("2014-07", freq="M")
```

```
In [366]: p + pd.offsets.MonthEnd(3)
```

```
Out[366]: Period('2014-10', 'M')
```

```
In [1]: p + pd.offsets.MonthBegin(3)
```

```
Traceback
```

```
...
```

```
ValueError: Input has different freq from Period(freq=M)
```

Taking the difference of Period instances with the same frequency will return the number of frequency units between them:

```
In [367]: pd.Period("2012", freq="A-DEC") - pd.Period("2002", freq="A-DEC")
```

```
Out[367]: <10 * YearEnds: month=12>
```

PeriodIndex and period_range

Regular sequences of Period objects can be collected in a PeriodIndex, which can be constructed using the period_range convenience function:

```
In [368]: prng = pd.period_range("1/1/2011", "1/1/2012", freq="M")
```

```
In [369]: prng
```

```
Out[369]:
```

```
PeriodIndex(['2011-01', '2011-02', '2011-03', '2011-04', '2011-05', '2011-06',
             '2011-07', '2011-08', '2011-09', '2011-10', '2011-11', '2011-12',
             '2012-01'],
            dtype='period[M]')
```

The PeriodIndex constructor can also be used directly:

```
In [370]: pd.PeriodIndex(["2011-1", "2011-2", "2011-3"], freq="M")
```

```
Out[370]: PeriodIndex(['2011-01', '2011-02', '2011-03'], dtype='period[M]')
```

Passing multiplied frequency outputs a sequence of Period which has multiplied span.

```
In [371]: pd.period_range(start="2014-01", freq="3M", periods=4)
```

```
Out[371]: PeriodIndex(['2014-01', '2014-04', '2014-07', '2014-10'], dtype='period[3M]')
```

If `start` or `end` are `Period` objects, they will be used as anchor endpoints for a `PeriodIndex` with frequency matching that of the `PeriodIndex` constructor.

```
In [372]: pd.period_range(
    ....:     start=pd.Period("2017Q1", freq="Q"), end=pd.Period("2017Q2", freq="Q"), 
    freq="M"
    ....: )
    ....:
Out[372]: PeriodIndex(['2017-03', '2017-04', '2017-05', '2017-06'], dtype='period[M']')
```

Just like `DatetimeIndex`, a `PeriodIndex` can also be used to index pandas objects:

```
In [373]: ps = pd.Series(np.random.randn(len(prng)), prng)

In [374]: ps
Out[374]:
2011-01    -2.916901
2011-02     0.514474
2011-03     1.346470
2011-04     0.816397
2011-05     2.258648
2011-06     0.494789
2011-07     0.301239
2011-08     0.464776
2011-09    -1.393581
2011-10     0.056780
2011-11     0.197035
2011-12     2.261385
2012-01    -0.329583
Freq: M, dtype: float64
```

`PeriodIndex` supports addition and subtraction with the same rule as `Period`.

```
In [375]: idx = pd.period_range("2014-07-01 09:00", periods=5, freq="H")

In [376]: idx
Out[376]:
PeriodIndex(['2014-07-01 09:00', '2014-07-01 10:00', '2014-07-01 11:00',
            '2014-07-01 12:00', '2014-07-01 13:00'],
            dtype='period[H']')

In [377]: idx + pd.offsets.Hour(2)
Out[377]:
PeriodIndex(['2014-07-01 11:00', '2014-07-01 12:00', '2014-07-01 13:00',
            '2014-07-01 14:00', '2014-07-01 15:00'],
            dtype='period[H']')

In [378]: idx = pd.period_range("2014-07", periods=5, freq="M")

In [379]: idx
Out[379]: PeriodIndex(['2014-07', '2014-08', '2014-09', '2014-10', '2014-11'],
                      dtype='period[M']')

In [380]: idx + pd.offsets.MonthEnd(3)
```

(continues on next page)

(continued from previous page)

```
Out[380]: PeriodIndex(['2014-10', '2014-11', '2014-12', '2015-01', '2015-02'], dtype='period[M]')
```

PeriodIndex has its own dtype named *period*, refer to *Period Dtypes*.

Period dtypes

PeriodIndex has a custom period dtype. This is a pandas extension dtype similar to the *timezone aware dtype* (datetime64[ns, tz]).

The period dtype holds the freq attribute and is represented with period[freq] like period[D] or period[M], using *frequency strings*.

```
In [381]: pi = pd.period_range("2016-01-01", periods=3, freq="M")
```

```
In [382]: pi
```

```
Out[382]: PeriodIndex(['2016-01', '2016-02', '2016-03'], dtype='period[M]')
```

```
In [383]: pi.dtype
```

```
Out[383]: period[M]
```

The period dtype can be used in .astype(...). It allows one to change the freq of a PeriodIndex like .asfreq() and convert a DatetimeIndex to PeriodIndex like to_period():

```
# change monthly freq to daily freq
```

```
In [384]: pi.astype("period[D]")
```

```
Out[384]: PeriodIndex(['2016-01-31', '2016-02-29', '2016-03-31'], dtype='period[D]')
```

```
# convert to DatetimeIndex
```

```
In [385]: pi.astype("datetime64[ns]")
```

```
Out[385]: DatetimeIndex(['2016-01-01', '2016-02-01', '2016-03-01'], dtype='datetime64[ns]', freq='MS')
```

```
# convert to PeriodIndex
```

```
In [386]: dti = pd.date_range("2011-01-01", freq="M", periods=3)
```

```
In [387]: dti
```

```
Out[387]: DatetimeIndex(['2011-01-31', '2011-02-28', '2011-03-31'], dtype='datetime64[ns]', freq='M')
```

```
In [388]: dti.astype("period[M]")
```

```
Out[388]: PeriodIndex(['2011-01', '2011-02', '2011-03'], dtype='period[M]')
```

PeriodIndex partial string indexing

PeriodIndex now supports partial string slicing with non-monotonic indexes.

New in version 1.1.0.

You can pass in dates and strings to Series and DataFrame with PeriodIndex, in the same manner as DatetimeIndex. For details, refer to [DatetimeIndex Partial String Indexing](#).

```
In [389]: ps["2011-01"]
Out[389]: -2.9169013294054507
```

```
In [390]: ps[datetime.datetime(2011, 12, 25):]
```

```
Out[390]:
2011-12    2.261385
2012-01   -0.329583
Freq: M, dtype: float64
```

```
In [391]: ps["10/31/2011":"12/31/2011"]
```

```
Out[391]:
2011-10    0.056780
2011-11    0.197035
2011-12    2.261385
Freq: M, dtype: float64
```

Passing a string representing a lower frequency than PeriodIndex returns partial sliced data.

```
In [392]: ps["2011"]
Out[392]:
2011-01    -2.916901
2011-02     0.514474
2011-03     1.346470
2011-04     0.816397
2011-05     2.258648
2011-06     0.494789
2011-07     0.301239
2011-08     0.464776
2011-09    -1.393581
2011-10     0.056780
2011-11     0.197035
2011-12     2.261385
Freq: M, dtype: float64
```

```
In [393]: dfp = pd.DataFrame(
.....:     np.random.randn(600, 1),
.....:     columns=["A"],
.....:     index=pd.period_range("2013-01-01 9:00", periods=600, freq="T"),
.....: )
.....:
```

```
In [394]: dfp
```

```
Out[394]:
          A
2013-01-01 09:00 -0.538468
2013-01-01 09:01 -1.365819
```

(continues on next page)

(continued from previous page)

2013-01-01 11:58  0.578798
2013-01-01 11:59 -0.685496
```

```
[120 rows x 1 columns]
```

Frequency conversion and resampling with PeriodIndex

The frequency of Period and PeriodIndex can be converted via the `asfreq` method. Let's start with the fiscal year 2011, ending in December:

```
In [397]: p = pd.Period("2011", freq="A-DEC")
```

```
In [398]: p
```

```
Out[398]: Period('2011', 'A-DEC')
```

We can convert it to a monthly frequency. Using the `how` parameter, we can specify whether to return the starting or ending month:

```
In [399]: p.asfreq("M", how="start")
```

```
Out[399]: Period('2011-01', 'M')
```

```
In [400]: p.asfreq("M", how="end")
```

```
Out[400]: Period('2011-12', 'M')
```

The shorthands ‘s’ and ‘e’ are provided for convenience:

```
In [401]: p.asfreq("M", "s")
```

```
Out[401]: Period('2011-01', 'M')
```

```
In [402]: p.asfreq("M", "e")
```

```
Out[402]: Period('2011-12', 'M')
```

Converting to a “super-period” (e.g., annual frequency is a super-period of quarterly frequency) automatically returns the super-period that includes the input period:

```
In [403]: p = pd.Period("2011-12", freq="M")
```

```
In [404]: p.asfreq("A-NOV")
```

```
Out[404]: Period('2012', 'A-NOV')
```

Note that since we converted to an annual frequency that ends the year in November, the monthly period of December 2011 is actually in the 2012 A-NOV period.

Period conversions with anchored frequencies are particularly useful for working with various quarterly data common to economics, business, and other fields. Many organizations define quarters relative to the month in which their fiscal year starts and ends. Thus, first quarter of 2011 could start in 2010 or a few months into 2011. Via anchored frequencies, pandas works for all quarterly frequencies Q-JAN through Q-DEC.

Q-DEC define regular calendar quarters:

```
In [405]: p = pd.Period("2012Q1", freq="Q-DEC")
```

```
In [406]: p.asfreq("D", "s")
```

```
Out[406]: Period('2012-01-01', 'D')
```

```
In [407]: p.asfreq("D", "e")
```

```
Out[407]: Period('2012-03-31', 'D')
```

Q-MAR defines fiscal year end in March:

```
In [408]: p = pd.Period("2011Q4", freq="Q-MAR")
```

```
In [409]: p.asfreq("D", "s")
```

```
Out[409]: Period('2011-01-01', 'D')
```

```
In [410]: p.asfreq("D", "e")
```

```
Out[410]: Period('2011-03-31', 'D')
```

2.20.12 Converting between representations

Timestamped data can be converted to PeriodIndex-ed data using `to_period` and vice-versa using `to_timestamp`:

```
In [411]: rng = pd.date_range("1/1/2012", periods=5, freq="M")
```

```
In [412]: ts = pd.Series(np.random.randn(len(rng)), index=rng)
```

```
In [413]: ts
```

```
Out[413]:
```

```
2012-01-31    1.931253  
2012-02-29   -0.184594  
2012-03-31    0.249656  
2012-04-30   -0.978151  
2012-05-31   -0.873389  
Freq: M, dtype: float64
```

```
In [414]: ps = ts.to_period()
```

```
In [415]: ps
```

```
Out[415]:
```

```
2012-01    1.931253  
2012-02   -0.184594  
2012-03    0.249656  
2012-04   -0.978151  
2012-05   -0.873389  
Freq: M, dtype: float64
```

```
In [416]: ps.to_timestamp()
```

```
Out[416]:
```

```
2012-01-01    1.931253  
2012-02-01   -0.184594  
2012-03-01    0.249656  
2012-04-01   -0.978151  
2012-05-01   -0.873389  
Freq: MS, dtype: float64
```

Remember that ‘s’ and ‘e’ can be used to return the timestamps at the start or end of the period:

```
In [417]: ps.to_timestamp("D", how="s")
```

```
Out[417]:
```

```
2012-01-01    1.931253  
2012-02-01   -0.184594  
2012-03-01    0.249656
```

(continues on next page)

(continued from previous page)

```
2012-04-01 -0.978151
2012-05-01 -0.873389
Freq: MS, dtype: float64
```

Converting between period and timestamp enables some convenient arithmetic functions to be used. In the following example, we convert a quarterly frequency with year ending in November to 9am of the end of the month following the quarter end:

```
In [418]: prng = pd.period_range("1990Q1", "2000Q4", freq="Q-NOV")

In [419]: ts = pd.Series(np.random.randn(len(prng)), prng)

In [420]: ts.index = (prng.asfreq("M", "e") + 1).asfreq("H", "s") + 9

In [421]: ts.head()
Out[421]:
1990-03-01 09:00 -0.109291
1990-06-01 09:00 -0.637235
1990-09-01 09:00 -1.735925
1990-12-01 09:00 2.096946
1991-03-01 09:00 -1.039926
Freq: H, dtype: float64
```

2.20.13 Representing out-of-bounds spans

If you have data that is outside of the `Timestamp` bounds, see [Timestamp limitations](#), then you can use a `PeriodIndex` and/or `Series` of Periods to do computations.

```
In [422]: span = pd.period_range("1215-01-01", "1381-01-01", freq="D")

In [423]: span
Out[423]:
PeriodIndex(['1215-01-01', '1215-01-02', '1215-01-03', '1215-01-04',
            '1215-01-05', '1215-01-06', '1215-01-07', '1215-01-08',
            '1215-01-09', '1215-01-10',
            ...
            '1380-12-23', '1380-12-24', '1380-12-25', '1380-12-26',
            '1380-12-27', '1380-12-28', '1380-12-29', '1380-12-30',
            '1380-12-31', '1381-01-01'],
            dtype='period[D]', length=60632)
```

To convert from an `int64` based YYYYMMDD representation.

```
In [424]: s = pd.Series([20121231, 20141130, 99991231])

In [425]: s
Out[425]:
0    20121231
1    20141130
2    99991231
dtype: int64
```

(continues on next page)

(continued from previous page)

```
In [426]: def conv(x):
.....      return pd.Period(year=x // 10000, month=x // 100 % 100, day=x % 100, freq=
←"D")
.....:

In [427]: s.apply(conv)
Out[427]:
0    2012-12-31
1    2014-11-30
2    9999-12-31
dtype: period[D]

In [428]: s.apply(conv)[2]
Out[428]: Period('9999-12-31', 'D')
```

These can easily be converted to a `PeriodIndex`:

```
In [429]: span = pd.PeriodIndex(s.apply(conv))

In [430]: span
Out[430]: PeriodIndex(['2012-12-31', '2014-11-30', '9999-12-31'], dtype='period[D']')
```

2.20.14 Time zone handling

pandas provides rich support for working with timestamps in different time zones using the `pytz` and `dateutil` libraries or `datetime.timezone` objects from the standard library.

Working with time zones

By default, pandas objects are time zone unaware:

```
In [431]: rng = pd.date_range("3/6/2012 00:00", periods=15, freq="D")

In [432]: rng.tz is None
Out[432]: True
```

To localize these dates to a time zone (assign a particular time zone to a naive date), you can use the `tz_localize` method or the `tz` keyword argument in `date_range()`, `Timestamp`, or `DatetimeIndex`. You can either pass `pytz` or `dateutil` time zone objects or Olson time zone database strings. Olson time zone strings will return `pytz` time zone objects by default. To return `dateutil` time zone objects, append `dateutil/` before the string.

- In `pytz` you can find a list of common (and less common) time zones using `from pytz import common_timezones, all_timezones`.
- `dateutil` uses the OS time zones so there isn't a fixed list available. For common zones, the names are the same as `pytz`.

```
In [433]: import dateutil

# pytz
```

(continues on next page)

(continued from previous page)

```
In [434]: rng_pytz = pd.date_range("3/6/2012 00:00", periods=3, freq="D", tz="Europe/London")
Out[434]: <DstTzInfo 'Europe/London' LMT-1 day, 23:59:00 STD>

# dateutil
In [436]: rng_dateutil = pd.date_range("3/6/2012 00:00", periods=3, freq="D")

In [437]: rng_dateutil = rng_dateutil.tz_localize("dateutil/Europe/London")

In [438]: rng_dateutil.tz
Out[438]: tzfile('/usr/share/zoneinfo/Europe/London')

# dateutil - utc special case
In [439]: rng_utc = pd.date_range(
    ....:     "3/6/2012 00:00",
    ....:     periods=3,
    ....:     freq="D",
    ....:     tz=dateutil.tz.tzutc(),
    ....: )
    ....:

In [440]: rng_utc.tz
Out[440]: tzutc()
```

New in version 0.25.0.

```
# datetime.timezone
In [441]: rng_utc = pd.date_range(
    ....:     "3/6/2012 00:00",
    ....:     periods=3,
    ....:     freq="D",
    ....:     tz=datetime.timezone.utc,
    ....: )
    ....:

In [442]: rng_utc.tz
Out[442]: datetime.timezone.utc
```

Note that the UTC time zone is a special case in `dateutil` and should be constructed explicitly as an instance of `dateutil.tz.tzutc`. You can also construct other time zones objects explicitly first.

```
In [443]: import pytz

# pytz
In [444]: tz_pytz = pytz.timezone("Europe/London")

In [445]: rng_pytz = pd.date_range("3/6/2012 00:00", periods=3, freq="D")

In [446]: rng_pytz = rng_pytz.tz_localize(tz_pytz)
```

(continues on next page)

(continued from previous page)

```
In [447]: rng_pytz.tz == tz_pytz
Out[447]: True

# dateutil
In [448]: tz_dateutil = dateutil.tz.gettz("Europe/London")

In [449]: rng_dateutil = pd.date_range("3/6/2012 00:00", periods=3, freq="D", tz=tz_
dateutil)

In [450]: rng_dateutil.tz == tz_dateutil
Out[450]: True
```

To convert a time zone aware pandas object from one time zone to another, you can use the `tz_convert` method.

```
In [451]: rng_pytz.tz_convert("US/Eastern")
Out[451]:
DatetimeIndex(['2012-03-05 19:00:00-05:00', '2012-03-06 19:00:00-05:00',
               '2012-03-07 19:00:00-05:00'],
              dtype='datetime64[ns, US/Eastern]', freq=None)
```

Note: When using pytz time zones, `DatetimeIndex` will construct a different time zone object than a `Timestamp` for the same time zone input. A `DatetimeIndex` can hold a collection of `Timestamp` objects that may have different UTC offsets and cannot be succinctly represented by one pytz time zone instance while one `Timestamp` represents one point in time with a specific UTC offset.

```
In [452]: dti = pd.date_range("2019-01-01", periods=3, freq="D", tz="US/Pacific")

In [453]: dti.tz
Out[453]: <DstTzInfo 'US/Pacific' LMT-1 day, 16:07:00 STD>

In [454]: ts = pd.Timestamp("2019-01-01", tz="US/Pacific")

In [455]: ts.tz
Out[455]: <DstTzInfo 'US/Pacific' PST-1 day, 16:00:00 STD>
```

Warning: Be wary of conversions between libraries. For some time zones, pytz and dateutil have different definitions of the zone. This is more of a problem for unusual time zones than for ‘standard’ zones like US/Eastern.

Warning: Be aware that a time zone definition across versions of time zone libraries may not be considered equal. This may cause problems when working with stored data that is localized using one version and operated on with a different version. See [here](#) for how to handle such a situation.

Warning: For pytz time zones, it is incorrect to pass a time zone object directly into the `datetime.datetime` constructor (e.g., `datetime.datetime(2011, 1, 1, tzinfo=pytz.timezone('US/Eastern'))`). Instead, the datetime needs to be localized using the `localize` method on the pytz time zone object.

Warning: Be aware that for times in the future, correct conversion between time zones (and UTC) cannot be guaranteed by any time zone library because a timezone's offset from UTC may be changed by the respective government.

Warning: If you are using dates beyond 2038-01-18, due to current deficiencies in the underlying libraries caused by the year 2038 problem, daylight saving time (DST) adjustments to timezone aware dates will not be applied. If and when the underlying libraries are fixed, the DST transitions will be applied.

For example, for two dates that are in British Summer Time (and so would normally be GMT+1), both the following asserts evaluate as true:

```
In [456]: d_2037 = "2037-03-31T010101"
In [457]: d_2038 = "2038-03-31T010101"
In [458]: DST = "Europe/London"
In [459]: assert pd.Timestamp(d_2037, tz=DST) != pd.Timestamp(d_2037, tz="GMT")
In [460]: assert pd.Timestamp(d_2038, tz=DST) == pd.Timestamp(d_2038, tz="GMT")
```

Under the hood, all timestamps are stored in UTC. Values from a time zone aware `DatetimeIndex` or `Timestamp` will have their fields (day, hour, minute, etc.) localized to the time zone. However, timestamps with the same UTC value are still considered to be equal even if they are in different time zones:

```
In [461]: rng_eastern = rng_utc.tz_convert("US/Eastern")
In [462]: rng_berlin = rng_utc.tz_convert("Europe/Berlin")
In [463]: rng_eastern[2]
Out[463]: Timestamp('2012-03-07 19:00:00-0500', tz='US/Eastern', freq='D')
In [464]: rng_berlin[2]
Out[464]: Timestamp('2012-03-08 01:00:00+0100', tz='Europe/Berlin', freq='D')
In [465]: rng_eastern[2] == rng_berlin[2]
Out[465]: True
```

Operations between `Series` in different time zones will yield UTC `Series`, aligning the data on the UTC timestamps:

```
In [466]: ts_utc = pd.Series(range(3), pd.date_range("20130101", periods=3, tz="UTC"))
In [467]: eastern = ts_utc.tz_convert("US/Eastern")
In [468]: berlin = ts_utc.tz_convert("Europe/Berlin")
In [469]: result = eastern + berlin
In [470]: result
Out[470]:
2013-01-01 00:00:00+00:00    0
```

(continues on next page)

(continued from previous page)

```
2013-01-02 00:00:00+00:00    2
2013-01-03 00:00:00+00:00    4
Freq: D, dtype: int64
```

In [471]: result.index

Out[471]:

```
DatetimeIndex(['2013-01-01 00:00:00+00:00', '2013-01-02 00:00:00+00:00',
               '2013-01-03 00:00:00+00:00'],
              dtype='datetime64[ns, UTC]', freq='D')
```

To remove time zone information, use `tz_localize(None)` or `tz_convert(None)`. `tz_localize(None)` will remove the time zone yielding the local time representation. `tz_convert(None)` will remove the time zone after converting to UTC time.

In [472]: didx = pd.date_range(start="2014-08-01 09:00", freq="H", periods=3, tz="US/
Eastern")

In [473]: didx

Out[473]:

```
DatetimeIndex(['2014-08-01 09:00:00-04:00', '2014-08-01 10:00:00-04:00',
               '2014-08-01 11:00:00-04:00'],
              dtype='datetime64[ns, US/Eastern]', freq='H')
```

In [474]: didx.tz_localize(None)

Out[474]:

```
DatetimeIndex(['2014-08-01 09:00:00', '2014-08-01 10:00:00',
               '2014-08-01 11:00:00'],
              dtype='datetime64[ns]', freq=None)
```

In [475]: didx.tz_convert(None)

Out[475]:

```
DatetimeIndex(['2014-08-01 13:00:00', '2014-08-01 14:00:00',
               '2014-08-01 15:00:00'],
              dtype='datetime64[ns]', freq='H')
```

`tz_convert(None)` is identical to `tz_convert('UTC').tz_localize(None)`

In [476]: didx.tz_convert("UTC").tz_localize(None)

Out[476]:

```
DatetimeIndex(['2014-08-01 13:00:00', '2014-08-01 14:00:00',
               '2014-08-01 15:00:00'],
              dtype='datetime64[ns]', freq=None)
```

Fold

New in version 1.1.0.

For ambiguous times, pandas supports explicitly specifying the keyword-only fold argument. Due to daylight saving time, one wall clock time can occur twice when shifting from summer to winter time; fold describes whether the datetime-like corresponds to the first (0) or the second time (1) the wall clock hits the ambiguous time. Fold is supported only for constructing from naive `datetime.datetime` (see [datetime documentation](#) for details) or from `Timestamp` or for constructing from components (see below). Only `dateutil` timezones are supported (see [dateutil documentation](#) for `dateutil` methods that deal with ambiguous datetimes) as `pytz` timezones do not support fold (see [pytz documentation](#) for details on how `pytz` deals with ambiguous datetimes). To localize an ambiguous datetime with `pytz`, please use `Timestamp.tz_localize()`. In general, we recommend to rely on `Timestamp.tz_localize()` when localizing ambiguous datetimes if you need direct control over how they are handled.

```
In [477]: pd.Timestamp(
.....:     datetime.datetime(2019, 10, 27, 1, 30, 0, 0),
.....:     tz="dateutil/Europe/London",
.....:     fold=0,
.....: )
.....:

Out[477]: Timestamp('2019-10-27 01:30:00+0100', tz='dateutil//usr/share/zoneinfo/Europe/
→London')
```

```
In [478]: pd.Timestamp(
.....:     year=2019,
.....:     month=10,
.....:     day=27,
.....:     hour=1,
.....:     minute=30,
.....:     tz="dateutil/Europe/London",
.....:     fold=1,
.....: )
.....:

Out[478]: Timestamp('2019-10-27 01:30:00+0000', tz='dateutil//usr/share/zoneinfo/Europe/
→London')
```

Ambiguous times when localizing

`tz_localize` may not be able to determine the UTC offset of a timestamp because daylight savings time (DST) in a local time zone causes some times to occur twice within one day (“clocks fall back”). The following options are available:

- 'raise': Raises a `pytz.AmbiguousTimeError` (the default behavior)
- 'infer': Attempt to determine the correct offset base on the monotonicity of the timestamps
- 'NaT': Replaces ambiguous times with `NaT`
- `bool`: True represents a DST time, False represents non-DST time. An array-like of `bool` values is supported for a sequence of times.

```
In [479]: rng_hourly = pd.DatetimeIndex(
.....:     ["11/06/2011 00:00", "11/06/2011 01:00", "11/06/2011 01:00", "11/06/2011
→02:00"]
```

(continues on next page)

(continued from previous page)

```
....: )
....:
```

This will fail as there are ambiguous times ('11/06/2011 01:00')

```
In [2]: rng_hourly.tz_localize('US/Eastern')
AmbiguousTimeError: Cannot infer dst time from Timestamp('2011-11-06 01:00:00'), try
→ using the 'ambiguous' argument
```

Handle these ambiguous times by specifying the following.

```
In [480]: rng_hourly.tz_localize("US/Eastern", ambiguous="infer")
Out[480]:
DatetimeIndex(['2011-11-06 00:00:00-04:00', '2011-11-06 01:00:00-04:00',
               '2011-11-06 01:00:00-05:00', '2011-11-06 02:00:00-05:00'],
              dtype='datetime64[ns, US/Eastern]', freq=None)

In [481]: rng_hourly.tz_localize("US/Eastern", ambiguous="NaT")
Out[481]:
DatetimeIndex(['2011-11-06 00:00:00-04:00', 'NaT', 'NaT',
               '2011-11-06 02:00:00-05:00'],
              dtype='datetime64[ns, US/Eastern]', freq=None)

In [482]: rng_hourly.tz_localize("US/Eastern", ambiguous=[True, True, False, False])
Out[482]:
DatetimeIndex(['2011-11-06 00:00:00-04:00', '2011-11-06 01:00:00-04:00',
               '2011-11-06 01:00:00-05:00', '2011-11-06 02:00:00-05:00'],
              dtype='datetime64[ns, US/Eastern]', freq=None)
```

Nonexistent times when localizing

A DST transition may also shift the local time ahead by 1 hour creating nonexistent local times (“clocks spring forward”). The behavior of localizing a timeseries with nonexistent times can be controlled by the `nonexistent` argument. The following options are available:

- `'raise'`: Raises a `pytz.NonExistentTimeError` (the default behavior)
- `'NaT'`: Replaces nonexistent times with `NaT`
- `'shift_forward'`: Shifts nonexistent times forward to the closest real time
- `'shift_backward'`: Shifts nonexistent times backward to the closest real time
- `timedelta` object: Shifts nonexistent times by the `timedelta` duration

```
In [483]: dti = pd.date_range(start="2015-03-29 02:30:00", periods=3, freq="H")

# 2:30 is a nonexistent time
```

Localization of nonexistent times will raise an error by default.

```
In [2]: dti.tz_localize('Europe/Warsaw')
NonExistentTimeError: 2015-03-29 02:30:00
```

Transform nonexistent times to `NaT` or shift the times.

```
In [484]: dti
```

```
Out[484]:
```

```
DatetimeIndex(['2015-03-29 02:30:00', '2015-03-29 03:30:00',
               '2015-03-29 04:30:00'],
              dtype='datetime64[ns]', freq='H')
```

```
In [485]: dti.tz_localize("Europe/Warsaw", nonexistent="shift_forward")
```

```
Out[485]:
```

```
DatetimeIndex(['2015-03-29 03:00:00+02:00', '2015-03-29 03:30:00+02:00',
               '2015-03-29 04:30:00+02:00'],
              dtype='datetime64[ns, Europe/Warsaw]', freq=None)
```

```
In [486]: dti.tz_localize("Europe/Warsaw", nonexistent="shift_backward")
```

```
Out[486]:
```

```
DatetimeIndex(['2015-03-29 01:59:59.99999999+01:00',
               '2015-03-29 03:30:00+02:00',
               '2015-03-29 04:30:00+02:00'],
              dtype='datetime64[ns, Europe/Warsaw]', freq=None)
```

```
In [487]: dti.tz_localize("Europe/Warsaw", nonexistent=pd.Timedelta(1, unit="H"))
```

```
Out[487]:
```

```
DatetimeIndex(['2015-03-29 03:30:00+02:00', '2015-03-29 03:30:00+02:00',
               '2015-03-29 04:30:00+02:00'],
              dtype='datetime64[ns, Europe/Warsaw]', freq=None)
```

```
In [488]: dti.tz_localize("Europe/Warsaw", nonexistent="NaT")
```

```
Out[488]:
```

```
DatetimeIndex(['NaT', '2015-03-29 03:30:00+02:00',
               '2015-03-29 04:30:00+02:00'],
              dtype='datetime64[ns, Europe/Warsaw]', freq=None)
```

Time zone series operations

A *Series* with time zone **naive** values is represented with a dtype of `datetime64[ns]`.

```
In [489]: s_naive = pd.Series(pd.date_range("20130101", periods=3))
```

```
In [490]: s_naive
```

```
Out[490]:
```

0	2013-01-01
1	2013-01-02
2	2013-01-03

```
dtype: datetime64[ns]
```

A *Series* with a time zone **aware** values is represented with a dtype of `datetime64[ns, tz]` where `tz` is the time zone

```
In [491]: s_aware = pd.Series(pd.date_range("20130101", periods=3, tz="US/Eastern"))
```

```
In [492]: s_aware
```

```
Out[492]:
```

0	2013-01-01 00:00:00-05:00
---	---------------------------

(continues on next page)

(continued from previous page)

```
1 2013-01-02 00:00:00-05:00
2 2013-01-03 00:00:00-05:00
dtype: datetime64[ns, US/Eastern]
```

Both of these `Series` time zone information can be manipulated via the `.dt` accessor, see [the dt accessor section](#).

For example, to localize and convert a naive stamp to time zone aware.

```
In [493]: s_naive.dt.tz_localize("UTC").dt.tz_convert("US/Eastern")
Out[493]:
0 2012-12-31 19:00:00-05:00
1 2013-01-01 19:00:00-05:00
2 2013-01-02 19:00:00-05:00
dtype: datetime64[ns, US/Eastern]
```

Time zone information can also be manipulated using the `astype` method. This method can convert between different timezone-aware dtypes.

```
# convert to a new time zone
In [494]: s_aware.astype("datetime64[ns, CET]")
Out[494]:
0 2013-01-01 06:00:00+01:00
1 2013-01-02 06:00:00+01:00
2 2013-01-03 06:00:00+01:00
dtype: datetime64[ns, CET]
```

Note: Using `Series.to_numpy()` on a `Series`, returns a NumPy array of the data. NumPy does not currently support time zones (even though it is *printing* in the local time zone!), therefore an object array of Timestamps is returned for time zone aware data:

```
In [495]: s_naive.to_numpy()
Out[495]:
array(['2013-01-01T00:00:00.000000000', '2013-01-02T00:00:00.000000000',
       '2013-01-03T00:00:00.000000000'], dtype='datetime64[ns]')

In [496]: s_aware.to_numpy()
Out[496]:
array([Timestamp('2013-01-01 00:00:00-0500', tz='US/Eastern'),
       Timestamp('2013-01-02 00:00:00-0500', tz='US/Eastern'),
       Timestamp('2013-01-03 00:00:00-0500', tz='US/Eastern')],  
      dtype=object)
```

By converting to an object array of Timestamps, it preserves the time zone information. For example, when converting back to a Series:

```
In [497]: pd.Series(s_aware.to_numpy())
Out[497]:
0 2013-01-01 00:00:00-05:00
1 2013-01-02 00:00:00-05:00
2 2013-01-03 00:00:00-05:00
dtype: datetime64[ns, US/Eastern]
```

However, if you want an actual NumPy `datetime64[ns]` array (with the values converted to UTC) instead of an array

of objects, you can specify the `dtype` argument:

```
In [498]: s_aware.to_numpy(dtype="datetime64[ns]")
Out[498]:
array(['2013-01-01T05:00:00.000000000', '2013-01-02T05:00:00.000000000',
       '2013-01-03T05:00:00.000000000'], dtype='datetime64[ns]')
```

2.21 Time deltas

Timedeltas are differences in times, expressed in difference units, e.g. days, hours, minutes, seconds. They can be both positive and negative.

`Timedelta` is a subclass of `datetime.timedelta`, and behaves in a similar manner, but allows compatibility with `np.timedelta64` types as well as a host of custom representation, parsing, and attributes.

2.21.1 Parsing

You can construct a `Timedelta` scalar through various arguments, including ISO 8601 Duration strings.

```
In [1]: import datetime

# strings
In [2]: pd.Timedelta("1 days")
Out[2]: Timedelta('1 days 00:00:00')

In [3]: pd.Timedelta("1 days 00:00:00")
Out[3]: Timedelta('1 days 00:00:00')

In [4]: pd.Timedelta("1 days 2 hours")
Out[4]: Timedelta('1 days 02:00:00')

In [5]: pd.Timedelta("-1 days 2 min 3us")
Out[5]: Timedelta('-2 days +23:57:59.999997')

# like datetime.timedelta
# note: these MUST be specified as keyword arguments
In [6]: pd.Timedelta(days=1, seconds=1)
Out[6]: Timedelta('1 days 00:00:01')

# integers with a unit
In [7]: pd.Timedelta(1, unit="d")
Out[7]: Timedelta('1 days 00:00:00')

# from a datetime.timedelta/np.timedelta64
In [8]: pd.Timedelta(datetime.timedelta(days=1, seconds=1))
Out[8]: Timedelta('1 days 00:00:01')

In [9]: pd.Timedelta(np.timedelta64(1, "ms"))
Out[9]: Timedelta('0 days 00:00:00.001000')
```

(continues on next page)

(continued from previous page)

```
# negative Timedeltas have this string repr
# to be more consistent with datetime.timedelta conventions
In [10]: pd.Timedelta("-1us")
Out[10]: Timedelta('-1 days +23:59:59.999999')

# a NaT
In [11]: pd.Timedelta("nan")
Out[11]: NaT

In [12]: pd.Timedelta("nat")
Out[12]: NaT

# ISO 8601 Duration strings
In [13]: pd.Timedelta("P0DT0H1M0S")
Out[13]: Timedelta('0 days 00:01:00')

In [14]: pd.Timedelta("P0DT0H0M0.000000123S")
Out[14]: Timedelta('0 days 00:00:00.000000123')
```

DateOffsets (Day, Hour, Minute, Second, Milli, Micro, Nano) can also be used in construction.

```
In [15]: pd.Timedelta(pd.offsets.Second(2))
Out[15]: Timedelta('0 days 00:00:02')
```

Further, operations among the scalars yield another scalar `Timedelta`.

```
In [16]: pd.Timedelta(pd.offsets.Day(2)) + pd.Timedelta(pd.offsets.Second(2)) + pd.
          Timedelta(
              ....:     "00:00:00.000123"
              ....: )
              ....:
Out[16]: Timedelta('2 days 00:00:02.000123')
```

to_timedelta

Using the top-level `pd.to_timedelta`, you can convert a scalar, array, list, or Series from a recognized timedelta format / value into a `Timedelta` type. It will construct Series if the input is a Series, a scalar if the input is scalar-like, otherwise it will output a `TimedeltaIndex`.

You can parse a single string to a `Timedelta`:

```
In [17]: pd.to_timedelta("1 days 06:05:01.00003")
Out[17]: Timedelta('1 days 06:05:01.000030')

In [18]: pd.to_timedelta("15.5us")
Out[18]: Timedelta('0 days 00:00:00.000015500')
```

or a list/array of strings:

```
In [19]: pd.to_timedelta(["1 days 06:05:01.00003", "15.5us", "nan"])
Out[19]: TimedeltaIndex(['1 days 06:05:01.000030', '0 days 00:00:00.000015500', NaT],
                         ..., dtype='timedelta64[ns]', freq=None)
```

The `unit` keyword argument specifies the unit of the Timedelta if the input is numeric:

```
In [20]: pd.to_timedelta(np.arange(5), unit="s")
Out[20]:
TimedeltaIndex(['0 days 00:00:00', '0 days 00:00:01', '0 days 00:00:02',
                 '0 days 00:00:03', '0 days 00:00:04'],
                dtype='timedelta64[ns]', freq=None)
```

```
In [21]: pd.to_timedelta(np.arange(5), unit="d")
Out[21]: TimedeltaIndex(['0 days', '1 days', '2 days', '3 days', '4 days'],
                         dtype='timedelta64[ns]', freq=None)
```

Warning: If a string or array of strings is passed as an input then the `unit` keyword argument will be ignored. If a string without units is passed then the default unit of nanoseconds is assumed.

Timedelta limitations

pandas represents Timedeltas in nanosecond resolution using 64 bit integers. As such, the 64 bit integer limits determine the Timedelta limits.

```
In [22]: pd.Timedelta.min
Out[22]: Timedelta('-106752 days +00:12:43.145224193')
```

```
In [23]: pd.Timedelta.max
Out[23]: Timedelta('106751 days 23:47:16.854775807')
```

2.21.2 Operations

You can operate on Series/DataFrames and construct `timedelta64[ns]` Series through subtraction operations on `datetime64[ns]` Series, or Timestamps.

```
In [24]: s = pd.Series(pd.date_range("2012-1-1", periods=3, freq="D"))
```

```
In [25]: td = pd.Series([pd.Timedelta(days=i) for i in range(3)])
```

```
In [26]: df = pd.DataFrame({"A": s, "B": td})
```

```
In [27]: df
```

```
Out[27]:
```

	A	B
0	2012-01-01	0 days
1	2012-01-02	1 days
2	2012-01-03	2 days

```
In [28]: df["C"] = df["A"] + df["B"]
```

```
In [29]: df
```

```
Out[29]:
```

	A	B	C
0	2012-01-01	0 days	2012-01-01

(continues on next page)

(continued from previous page)

```
1 2012-01-02 1 days 2012-01-03
2 2012-01-03 2 days 2012-01-05
```

In [30]: df.dtypes

Out[30]:

```
A    datetime64[ns]
B    timedelta64[ns]
C    datetime64[ns]
dtype: object
```

In [31]: s - s.max()

Out[31]:

```
0   -2 days
1   -1 days
2    0 days
dtype: timedelta64[ns]
```

In [32]: s - datetime.datetime(2011, 1, 1, 3, 5)

Out[32]:

```
0   364 days 20:55:00
1   365 days 20:55:00
2   366 days 20:55:00
dtype: timedelta64[ns]
```

In [33]: s + datetime.timedelta(minutes=5)

Out[33]:

```
0   2012-01-01 00:05:00
1   2012-01-02 00:05:00
2   2012-01-03 00:05:00
dtype: datetime64[ns]
```

In [34]: s + pd.offsets.Minute(5)

Out[34]:

```
0   2012-01-01 00:05:00
1   2012-01-02 00:05:00
2   2012-01-03 00:05:00
dtype: datetime64[ns]
```

In [35]: s + pd.offsets.Minute(5) + pd.offsets.Milli(5)

Out[35]:

```
0   2012-01-01 00:05:00.005
1   2012-01-02 00:05:00.005
2   2012-01-03 00:05:00.005
dtype: datetime64[ns]
```

Operations with scalars from a timedelta64[ns] series:

In [36]: y = s - s[0]

In [37]: y

Out[37]:

```
0   0 days
```

(continues on next page)

(continued from previous page)

```
1 1 days
2 2 days
dtype: timedelta64[ns]
```

Series of timedeltas with NaT values are supported:

```
In [38]: y = s - s.shift()
```

```
In [39]: y
```

```
Out[39]:
```

```
0      NaT
1 1 days
2 1 days
dtype: timedelta64[ns]
```

Elements can be set to NaT using np.nan analogously to datetimes:

```
In [40]: y[1] = np.nan
```

```
In [41]: y
```

```
Out[41]:
```

```
0      NaT
1      NaT
2 1 days
dtype: timedelta64[ns]
```

Operands can also appear in a reversed order (a singular object operated with a Series):

```
In [42]: s.max() - s
```

```
Out[42]:
```

```
0 2 days
1 1 days
2 0 days
dtype: timedelta64[ns]
```

```
In [43]: datetime.datetime(2011, 1, 1, 3, 5) - s
```

```
Out[43]:
```

```
0 -365 days +03:05:00
1 -366 days +03:05:00
2 -367 days +03:05:00
dtype: timedelta64[ns]
```

```
In [44]: datetime.timedelta(minutes=5) + s
```

```
Out[44]:
```

```
0 2012-01-01 00:05:00
1 2012-01-02 00:05:00
2 2012-01-03 00:05:00
dtype: datetime64[ns]
```

min, max and the corresponding idxmin, idxmax operations are supported on frames:

```
In [45]: A = s - pd.Timestamp("20120101") - pd.Timedelta("00:05:05")
```

(continues on next page)

(continued from previous page)

```
In [46]: B = s - pd.Series(pd.date_range("2012-1-2", periods=3, freq="D"))
```

```
In [47]: df = pd.DataFrame({"A": A, "B": B})
```

```
In [48]: df
```

```
Out[48]:
```

```
          A      B  
0 -1 days +23:54:55 -1 days  
1  0 days 23:54:55 -1 days  
2  1 days 23:54:55 -1 days
```

```
In [49]: df.min()
```

```
Out[49]:
```

```
A -1 days +23:54:55  
B -1 days +00:00:00  
dtype: timedelta64[ns]
```

```
In [50]: df.min(axis=1)
```

```
Out[50]:
```

```
0 -1 days  
1 -1 days  
2 -1 days  
dtype: timedelta64[ns]
```

```
In [51]: df.idxmin()
```

```
Out[51]:
```

```
A 0  
B 0  
dtype: int64
```

```
In [52]: df.idxmax()
```

```
Out[52]:
```

```
A 2  
B 0  
dtype: int64
```

`min`, `max`, `idxmin`, `idxmax` operations are supported on Series as well. A scalar result will be a `Timedelta`.

```
In [53]: df.min().max()
```

```
Out[53]: Timedelta('-1 days +23:54:55')
```

```
In [54]: df.min(axis=1).min()
```

```
Out[54]: Timedelta('-1 days +00:00:00')
```

```
In [55]: df.min().idxmax()
```

```
Out[55]: 'A'
```

```
In [56]: df.min(axis=1).idxmin()
```

```
Out[56]: 0
```

You can `fillna` on `timedeltas`, passing a `timedelta` to get a particular value.

```
In [57]: y.fillna(pd.Timedelta(0))
Out[57]:
0    0 days
1    0 days
2    1 days
dtype: timedelta64[ns]

In [58]: y.fillna(pd.Timedelta(10, unit="s"))
Out[58]:
0    0 days 00:00:10
1    0 days 00:00:10
2    1 days 00:00:00
dtype: timedelta64[ns]

In [59]: y.fillna(pd.Timedelta("-1 days, 00:00:05"))
Out[59]:
0   -1 days +00:00:05
1   -1 days +00:00:05
2    1 days 00:00:00
dtype: timedelta64[ns]
```

You can also negate, multiply and use abs on Timedeltas:

```
In [60]: td1 = pd.Timedelta("-1 days 2 hours 3 seconds")
In [61]: td1
Out[61]: Timedelta('-2 days +21:59:57')

In [62]: -1 * td1
Out[62]: Timedelta('1 days 02:00:03')

In [63]: -td1
Out[63]: Timedelta('1 days 02:00:03')

In [64]: abs(td1)
Out[64]: Timedelta('1 days 02:00:03')
```

2.21.3 Reductions

Numeric reduction operation for `timedelta64[ns]` will return `Timedelta` objects. As usual `NaT` are skipped during evaluation.

```
In [65]: y2 = pd.Series(
.....:     pd.to_timedelta(["-1 days +00:00:05", "nat", "-1 days +00:00:05", "1 days"])
.....: )
.....:

In [66]: y2
Out[66]:
0   -1 days +00:00:05
1                NaT
2   -1 days +00:00:05
```

(continues on next page)

(continued from previous page)

```

3    1 days 00:00:00
dtype: timedelta64[ns]

In [67]: y2.mean()
Out[67]: Timedelta('-1 days +16:00:03.333333334')

In [68]: y2.median()
Out[68]: Timedelta('-1 days +00:00:05')

In [69]: y2.quantile(0.1)
Out[69]: Timedelta('-1 days +00:00:05')

In [70]: y2.sum()
Out[70]: Timedelta('-1 days +00:00:10')

```

2.21.4 Frequency conversion

Timedelta Series, TimedeltaIndex, and Timedelta scalars can be converted to other ‘frequencies’ by dividing by another timedelta, or by astyping to a specific timedelta type. These operations yield Series and propagate NaT → nan. Note that division by the NumPy scalar is true division, while astyping is equivalent of floor division.

```

In [71]: december = pd.Series(pd.date_range("20121201", periods=4))

In [72]: january = pd.Series(pd.date_range("20130101", periods=4))

In [73]: td = january - december

In [74]: td[2] += datetime.timedelta(minutes=5, seconds=3)

In [75]: td[3] = np.nan

In [76]: td
Out[76]:
0   31 days 00:00:00
1   31 days 00:00:00
2   31 days 00:05:03
3           NaT
dtype: timedelta64[ns]

# to days
In [77]: td / np.timedelta64(1, "D")
Out[77]:
0    31.000000
1    31.000000
2    31.003507
3        NaN
dtype: float64

In [78]: td.astype("timedelta64[D]")
Out[78]:
0    31.0

```

(continues on next page)

(continued from previous page)

```

1    31.0
2    31.0
3      NaN
dtype: float64

# to seconds
In [79]: td / np.timedelta64(1, "s")
Out[79]:
0    2678400.0
1    2678400.0
2    2678703.0
3        NaN
dtype: float64

In [80]: td.astype("timedelta64[s]")
Out[80]:
0    2678400.0
1    2678400.0
2    2678703.0
3        NaN
dtype: float64

# to months (these are constant months)
In [81]: td / np.timedelta64(1, "M")
Out[81]:
0    1.018501
1    1.018501
2    1.018617
3        NaN
dtype: float64

```

Dividing or multiplying a `timedelta64[ns]` Series by an integer or integer Series yields another `timedelta64[ns]` dtypes Series.

```

In [82]: td * -1
Out[82]:
0   -31 days +00:00:00
1   -31 days +00:00:00
2   -32 days +23:54:57
3        NaT
dtype: timedelta64[ns]

In [83]: td * pd.Series([1, 2, 3, 4])
Out[83]:
0   31 days 00:00:00
1   62 days 00:00:00
2   93 days 00:15:09
3        NaT
dtype: timedelta64[ns]

```

Rounded division (floor-division) of a `timedelta64[ns]` Series by a scalar Timedelta gives a series of integers.

```
In [84]: td // pd.Timedelta(days=3, hours=4)
```

```
Out[84]:
```

```
0    9.0  
1    9.0  
2    9.0  
3    NaN  
dtype: float64
```

```
In [85]: pd.Timedelta(days=3, hours=4) // td
```

```
Out[85]:
```

```
0    0.0  
1    0.0  
2    0.0  
3    NaN  
dtype: float64
```

The mod (%) and divmod operations are defined for `Timedelta` when operating with another `timedelta-like` or with a numeric argument.

```
In [86]: pd.Timedelta(hours=37) % datetime.timedelta(hours=2)
```

```
Out[86]: Timedelta('0 days 01:00:00')
```

```
# divmod against a timedelta-like returns a pair (int, Timedelta)
```

```
In [87]: divmod(datetime.timedelta(hours=2), pd.Timedelta(minutes=11))
```

```
Out[87]: (10, Timedelta('0 days 00:10:00'))
```

```
# divmod against a numeric returns a pair (Timedelta, Timedelta)
```

```
In [88]: divmod(pd.Timedelta(hours=25), 864000000000000000)
```

```
Out[88]: (Timedelta('0 days 00:00:00.000000001'), Timedelta('0 days 01:00:00'))
```

2.21.5 Attributes

You can access various components of the `Timedelta` or `TimedeltaIndex` directly using the attributes `days`, `seconds`, `microseconds`, `nanoseconds`. These are identical to the values returned by `datetime.timedelta`, in that, for example, the `.seconds` attribute represents the number of seconds ≥ 0 and < 1 day. These are signed according to whether the `Timedelta` is signed.

These operations can also be directly accessed via the `.dt` property of the `Series` as well.

Note: Note that the attributes are NOT the displayed values of the `Timedelta`. Use `.components` to retrieve the displayed values.

For a `Series`:

```
In [89]: td.dt.days
```

```
Out[89]:
```

```
0    31.0  
1    31.0  
2    31.0  
3    NaN  
dtype: float64
```

(continues on next page)

(continued from previous page)

In [90]: td.dt.seconds**Out[90]:**

```
0      0.0
1      0.0
2    303.0
3      NaN
dtype: float64
```

You can access the value of the fields for a scalar Timedelta directly.

In [91]: tds = pd.Timedelta("31 days 5 min 3 sec")**In [92]:** tds.days**Out[92]:** 31**In [93]:** tds.seconds**Out[93]:** 303**In [94]:** (-tds).seconds**Out[94]:** 86097

You can use the .components property to access a reduced form of the timedelta. This returns a DataFrame indexed similarly to the Series. These are the *displayed* values of the Timedelta.

In [95]: td.dt.components**Out[95]:**

	days	hours	minutes	seconds	milliseconds	microseconds	nanoseconds
0	31.0	0.0	0.0	0.0	0.0	0.0	0.0
1	31.0	0.0	0.0	0.0	0.0	0.0	0.0
2	31.0	0.0	5.0	3.0	0.0	0.0	0.0
3	NaN	NaN	NaN	NaN	NaN	NaN	NaN

In [96]: td.dt.components.seconds**Out[96]:**

```
0      0.0
1      0.0
2      3.0
3      NaN
Name: seconds, dtype: float64
```

You can convert a Timedelta to an ISO 8601 Duration string with the .isoformat method

```
In [97]: pd.Timedelta(
.....:     days=6, minutes=50, seconds=3, milliseconds=10, microseconds=10, nanoseconds=12
.....: ).isoformat()
.....:
Out[97]: 'P6DT0H50M3.010010012S'
```

2.21.6 TimedeltaIndex

To generate an index with time delta, you can use either the `TimedeltaIndex` or the `timedelta_range()` constructor. Using `TimedeltaIndex` you can pass string-like, `Timedelta`, `timedelta`, or `np.timedelta64` objects. Passing `np.nan/pd.NaT/nat` will represent missing values.

```
In [98]: pd.TimedeltaIndex(
.....      [
.....      "1 days",
.....      "1 days, 00:00:05",
.....      np.timedelta64(2, "D"),
.....      datetime.timedelta(days=2, seconds=2),
.....    ]
.....)
Out[98]:
TimedeltaIndex(['1 days 00:00:00', '1 days 00:00:05', '2 days 00:00:00',
                 '2 days 00:00:02'],
               dtype='timedelta64[ns]', freq=None)
```

The string ‘infer’ can be passed in order to set the frequency of the index as the inferred frequency upon creation:

```
In [99]: pd.TimedeltaIndex(["0 days", "10 days", "20 days"], freq="infer")
Out[99]: TimedeltaIndex(['0 days', '10 days', '20 days'], dtype='timedelta64[ns]', freq=
↪ '10D')
```

Generating ranges of time deltas

Similar to `date_range()`, you can construct regular ranges of a `TimedeltaIndex` using `timedelta_range()`. The default frequency for `timedelta_range` is calendar day:

```
In [100]: pd.timedelta_range(start="1 days", periods=5)
Out[100]: TimedeltaIndex(['1 days', '2 days', '3 days', '4 days', '5 days'], dtype=
↪ 'timedelta64[ns]', freq='D')
```

Various combinations of `start`, `end`, and `periods` can be used with `timedelta_range`:

```
In [101]: pd.timedelta_range(start="1 days", end="5 days")
Out[101]: TimedeltaIndex(['1 days', '2 days', '3 days', '4 days', '5 days'], dtype=
↪ 'timedelta64[ns]', freq='D')

In [102]: pd.timedelta_range(end="10 days", periods=4)
Out[102]: TimedeltaIndex(['7 days', '8 days', '9 days', '10 days'], dtype=
↪ 'timedelta64[ns]', freq='D')
```

The `freq` parameter can be passed a variety of *frequency aliases*:

```
In [103]: pd.timedelta_range(start="1 days", end="2 days", freq="30T")
Out[103]:
TimedeltaIndex(['1 days 00:00:00', '1 days 00:30:00', '1 days 01:00:00',
                 '1 days 01:30:00', '1 days 02:00:00', '1 days 02:30:00',
                 '1 days 03:00:00', '1 days 03:30:00', '1 days 04:00:00',
```

(continues on next page)

(continued from previous page)

```
'1 days 04:30:00', '1 days 05:00:00', '1 days 05:30:00',
'1 days 06:00:00', '1 days 06:30:00', '1 days 07:00:00',
'1 days 07:30:00', '1 days 08:00:00', '1 days 08:30:00',
'1 days 09:00:00', '1 days 09:30:00', '1 days 10:00:00',
'1 days 10:30:00', '1 days 11:00:00', '1 days 11:30:00',
'1 days 12:00:00', '1 days 12:30:00', '1 days 13:00:00',
'1 days 13:30:00', '1 days 14:00:00', '1 days 14:30:00',
'1 days 15:00:00', '1 days 15:30:00', '1 days 16:00:00',
'1 days 16:30:00', '1 days 17:00:00', '1 days 17:30:00',
'1 days 18:00:00', '1 days 18:30:00', '1 days 19:00:00',
'1 days 19:30:00', '1 days 20:00:00', '1 days 20:30:00',
'1 days 21:00:00', '1 days 21:30:00', '1 days 22:00:00',
'1 days 22:30:00', '1 days 23:00:00', '1 days 23:30:00',
'2 days 00:00:00'],
dtype='timedelta64[ns]', freq='30T')
```

In [104]: `pd.timedelta_range(start="1 days", periods=5, freq="2D5H")`

Out[104]:

```
TimedeltaIndex(['1 days 00:00:00', '3 days 05:00:00', '5 days 10:00:00',
               '7 days 15:00:00', '9 days 20:00:00'],
              dtype='timedelta64[ns]', freq='53H')
```

Specifying `start`, `end`, and `periods` will generate a range of evenly spaced timedeltas from `start` to `end` inclusively, with `periods` number of elements in the resulting `TimedeltaIndex`:

In [105]: `pd.timedelta_range("0 days", "4 days", periods=5)`

Out[105]: `TimedeltaIndex(['0 days', '1 days', '2 days', '3 days', '4 days'], dtype='timedelta64[ns]', freq=None)`

In [106]: `pd.timedelta_range("0 days", "4 days", periods=10)`

Out[106]:

```
TimedeltaIndex(['0 days 00:00:00', '0 days 10:40:00', '0 days 21:20:00',
               '1 days 08:00:00', '1 days 18:40:00', '2 days 05:20:00',
               '2 days 16:00:00', '3 days 02:40:00', '3 days 13:20:00',
               '4 days 00:00:00'],
              dtype='timedelta64[ns]', freq=None)
```

Using the TimedeltaIndex

Similarly to other of the datetime-like indices, `DatetimeIndex` and `PeriodIndex`, you can use `TimedeltaIndex` as the index of pandas objects.

In [107]: `s = pd.Series(
.....: np.arange(100),
.....: index=pd.timedelta_range("1 days", periods=100, freq="h"),
.....:)
.....:`

In [108]: `s`

Out[108]:

```
1 days 00:00:00    0
```

(continues on next page)

(continued from previous page)

```
1 days 01:00:00    1
1 days 02:00:00    2
1 days 03:00:00    3
1 days 04:00:00    4
...
4 days 23:00:00    95
5 days 00:00:00    96
5 days 01:00:00    97
5 days 02:00:00    98
5 days 03:00:00    99
Freq: H, Length: 100, dtype: int64
```

Selections work similarly, with coercion on string-likes and slices:

```
In [109]: s["1 day":"2 day"]
Out[109]:
1 days 00:00:00    0
1 days 01:00:00    1
1 days 02:00:00    2
1 days 03:00:00    3
1 days 04:00:00    4
...
2 days 19:00:00    43
2 days 20:00:00    44
2 days 21:00:00    45
2 days 22:00:00    46
2 days 23:00:00    47
Freq: H, Length: 48, dtype: int64
```

```
In [110]: s["1 day 01:00:00"]
Out[110]: 1

In [111]: s[pd.Timedelta("1 day 1h")]
Out[111]: 1
```

Furthermore you can use partial string selection and the range will be inferred:

```
In [112]: s["1 day":"1 day 5 hours"]
Out[112]:
1 days 00:00:00    0
1 days 01:00:00    1
1 days 02:00:00    2
1 days 03:00:00    3
1 days 04:00:00    4
1 days 05:00:00    5
Freq: H, dtype: int64
```

Operations

Finally, the combination of TimedeltaIndex with DatetimeIndex allow certain combination operations that are NaT preserving:

```
In [113]: tdi = pd.TimedeltaIndex(["1 days", pd.NaT, "2 days"])

In [114]: tdi.to_list()
Out[114]: [Timedelta('1 days 00:00:00'), NaT, Timedelta('2 days 00:00:00')]

In [115]: dti = pd.date_range("20130101", periods=3)

In [116]: dti.to_list()
Out[116]:
[Timestamp('2013-01-01 00:00:00', freq='D'),
 Timestamp('2013-01-02 00:00:00', freq='D'),
 Timestamp('2013-01-03 00:00:00', freq='D')]

In [117]: (dti + tdi).to_list()
Out[117]: [Timestamp('2013-01-02 00:00:00'), NaT, Timestamp('2013-01-05 00:00:00')]

In [118]: (dti - tdi).to_list()
Out[118]: [Timestamp('2012-12-31 00:00:00'), NaT, Timestamp('2013-01-01 00:00:00')]
```

Conversions

Similarly to frequency conversion on a Series above, you can convert these indices to yield another Index.

```
In [119]: tdi / np.timedelta64(1, "s")
Out[119]: Float64Index([86400.0, nan, 172800.0], dtype='float64')

In [120]: tdi.astype("timedelta64[s]")
Out[120]: Float64Index([86400.0, nan, 172800.0], dtype='float64')
```

Scalars type ops work as well. These can potentially return a *different* type of index.

```
# adding or timedelta and date -> datelike
In [121]: tdi + pd.Timestamp("20130101")
Out[121]: DatetimeIndex(['2013-01-02', 'NaT', '2013-01-03'], dtype='datetime64[ns]', freq=None)

# subtraction of a date and a timedelta -> datelike
# note that trying to subtract a date from a Timedelta will raise an exception
In [122]: (pd.Timestamp("20130101") - tdi).to_list()
Out[122]: [Timestamp('2012-12-31 00:00:00'), NaT, Timestamp('2012-12-30 00:00:00')]

# timedelta + timedelta -> timedelta
In [123]: tdi + pd.Timedelta("10 days")
Out[123]: TimedeltaIndex(['11 days', NaT, '12 days'], dtype='timedelta64[ns]', freq=None)

# division can result in a Timedelta if the divisor is an integer
In [124]: tdi / 2
Out[124]: TimedeltaIndex(['0 days 12:00:00', NaT, '1 days 00:00:00'], dtype='timedelta64[ns]', freq=None)
```

(continues on next page)

(continued from previous page)

```
# or a Float64Index if the divisor is a Timedelta
In [125]: tdi / tdi[0]
Out[125]: Float64Index([1.0, nan, 2.0], dtype='float64')
```

2.21.7 Resampling

Similar to [timeseries resampling](#), we can resample with a TimedeltaIndex.

```
In [126]: s.resample("D").mean()
Out[126]:
1 days    11.5
2 days    35.5
3 days    59.5
4 days    83.5
5 days    97.5
Freq: D, dtype: float64
```

2.22 Options and settings

2.22.1 Overview

pandas has an options system that lets you customize some aspects of its behaviour, display-related options being those the user is most likely to adjust.

Options have a full “dotted-style”, case-insensitive name (e.g. `display.max_rows`). You can get/set options directly as attributes of the top-level `options` attribute:

```
In [1]: import pandas as pd
In [2]: pd.options.display.max_rows
Out[2]: 15
In [3]: pd.options.display.max_rows = 999
In [4]: pd.options.display.max_rows
Out[4]: 999
```

The API is composed of 5 relevant functions, available directly from the `pandas` namespace:

- `get_option()` / `set_option()` - get/set the value of a single option.
- `reset_option()` - reset one or more options to their default value.
- `describe_option()` - print the descriptions of one or more options.
- `option_context()` - execute a codeblock with a set of options that revert to prior settings after execution.

Note: Developers can check out [pandas/core/config_init.py](#) for more information.

All of the functions above accept a regexp pattern (`re.search` style) as an argument, and so passing in a substring will work - as long as it is unambiguous:

```
In [5]: pd.get_option("display.chop_threshold")
In [6]: pd.set_option("display.chop_threshold", 2)
In [7]: pd.get_option("display.chop_threshold")
Out[7]: 2
In [8]: pd.set_option("chop", 4)
In [9]: pd.get_option("display.chop_threshold")
Out[9]: 4
```

The following will **not work** because it matches multiple option names, e.g. `display.max_colwidth`, `display.max_rows`, `display.max_columns`:

```
In [10]: try:
....:     pd.get_option("max")
....: except KeyError as e:
....:     print(e)
....:
'Pattern matched multiple keys'
```

Note: Using this form of shorthand may cause your code to break if new options with similar names are added in future versions.

You can get a list of available options and their descriptions with `describe_option`. When called with no argument `describe_option` will print out the descriptions for all available options.

2.22.2 Getting and setting options

As described above, `get_option()` and `set_option()` are available from the pandas namespace. To change an option, call `set_option('option regex', new_value)`.

```
In [11]: pd.get_option("mode.sim_interactive")
Out[11]: False
In [12]: pd.set_option("mode.sim_interactive", True)
In [13]: pd.get_option("mode.sim_interactive")
Out[13]: True
```

Note: The option ‘`mode.sim_interactive`’ is mostly used for debugging purposes.

All options also have a default value, and you can use `reset_option` to do just that:

```
In [14]: pd.get_option("display.max_rows")
Out[14]: 60
In [15]: pd.set_option("display.max_rows", 999)
In [16]: pd.get_option("display.max_rows")
Out[16]: 999
```

(continues on next page)

(continued from previous page)

```
In [17]: pd.reset_option("display.max_rows")
```

```
In [18]: pd.get_option("display.max_rows")
```

```
Out[18]: 60
```

It's also possible to reset multiple options at once (using a regex):

```
In [19]: pd.reset_option("^display")
```

option_context context manager has been exposed through the top-level API, allowing you to execute code with given option values. Option values are restored automatically when you exit the `with` block:

```
In [20]: with pd.option_context("display.max_rows", 10, "display.max_columns", 5):
    ....:     print(pd.get_option("display.max_rows"))
    ....:     print(pd.get_option("display.max_columns"))
    ....:
```

```
10
```

```
5
```

```
In [21]: print(pd.get_option("display.max_rows"))
```

```
60
```

```
In [22]: print(pd.get_option("display.max_columns"))
```

```
0
```

2.22.3 Setting startup options in Python/IPython environment

Using startup scripts for the Python/IPython environment to import pandas and set options makes working with pandas more efficient. To do this, create a .py or .ipy script in the startup directory of the desired profile. An example where the startup folder is in a default IPython profile can be found at:

```
$IPYTHONDIR/profile_default/startup
```

More information can be found in the [IPython documentation](#). An example startup script for pandas is displayed below:

```
import pandas as pd

pd.set_option("display.max_rows", 999)
pd.set_option("display.precision", 5)
```

2.22.4 Frequently used options

The following is a walk-through of the more frequently used display options.

`display.max_rows` and `display.max_columns` sets the maximum number of rows and columns displayed when a frame is pretty-printed. Truncated lines are replaced by an ellipsis.

```
In [23]: df = pd.DataFrame(np.random.randn(7, 2))
```

```
In [24]: pd.set_option("display.max_rows", 7)
```

(continues on next page)

(continued from previous page)

```
In [25]: df
Out[25]:
      0      1
0  0.469112 -0.282863
1 -1.509059 -1.135632
2  1.212112 -0.173215
3  0.119209 -1.044236
4 -0.861849 -2.104569
5 -0.494929  1.071804
6  0.721555 -0.706771

In [26]: pd.set_option("display.max_rows", 5)

In [27]: df
Out[27]:
      0      1
0  0.469112 -0.282863
1 -1.509059 -1.135632
..
5  -0.494929  1.071804
6  0.721555 -0.706771

[7 rows x 2 columns]

In [28]: pd.reset_option("display.max_rows")
```

Once the `display.max_rows` is exceeded, the `display.min_rows` options determines how many rows are shown in the truncated repr.

```
In [29]: pd.set_option("display.max_rows", 8)

In [30]: pd.set_option("display.min_rows", 4)

# below max_rows -> all rows shown
In [31]: df = pd.DataFrame(np.random.randn(7, 2))

In [32]: df
Out[32]:
      0      1
0 -1.039575  0.271860
1 -0.424972  0.567020
2  0.276232 -1.087401
3 -0.673690  0.113648
4 -1.478427  0.524988
5  0.404705  0.577046
6 -1.715002 -1.039268

# above max_rows -> only min_rows (4) rows shown
In [33]: df = pd.DataFrame(np.random.randn(9, 2))

In [34]: df
Out[34]:
```

(continues on next page)

(continued from previous page)

```

    0      1
0 -0.370647 -1.157892
1 -1.344312  0.844885
...
7  0.276662 -0.472035
8 -0.013960 -0.362543

[9 rows x 2 columns]

```

In [35]: `pd.reset_option("display.max_rows")`

In [36]: `pd.reset_option("display.min_rows")`

`display.expand_frame_repr` allows for the representation of dataframes to stretch across pages, wrapped over the full column vs row-wise.

In [37]: `df = pd.DataFrame(np.random.randn(5, 10))`

In [38]: `pd.set_option("expand_frame_repr", True)`

In [39]: `df`

Out[39]:

	0	1	2	3	4	5	6	7	8

dtypes: float64(10)
memory usage: 928.0 bytes
```

In [60]: `pd.set_option("max_info_columns", 5)`

In [61]: `df.info()`
`<class 'pandas.core.frame.DataFrame'>`
`RangeIndex: 10 entries, 0 to 9`
`Columns: 10 entries, 0 to 9`
`dtypes: float64(10)`
`memory usage: 928.0 bytes`

In [62]: `pd.reset_option("max_info_columns")`

`display.max_info_rows`: `df.info()` will usually show null-counts for each column. For large frames this can be quite slow. `max_info_rows` and `max_info_cols` limit this null check only to frames with smaller dimensions than specified. Note that you can specify the option `df.info(null_counts=True)` to override on showing a particular frame.

In [63]: `df = pd.DataFrame(np.random.choice([0, 1, np.nan], size=(10, 10)))`

In [64]: `df`

Out[64]:

	0	1	2	3	4	5	6	7	8	9

2.22.5 Available options

Option	Default	Function
<code>display.chop_threshold</code>	None	If set to a float value, all float values smaller than the given threshold will be displayed as exactly 0 by <code>repr</code> and <code>friends</code> .
<code>display.colheader_justify</code>	right	Controls the justification of column headers. used by <code>DataFrameFormatter</code> .
<code>display.column_space</code>	12	No description available.
<code>display.date_dayfirst</code>	False	When True, prints and parses dates with the day first, eg 20/01/2005
<code>display.date_yearfirst</code>	False	When True, prints and parses dates with the year first, eg 2005/01/20
<code>display.encoding</code>	UTF-8	Defaults to the detected encoding of the console. Specifies the encoding to be used for strings returned by <code>to_string</code> , these are generally strings meant to be displayed on the console.
<code>display.expand_frame_repr</code>	True	Whether to print out the full <code>DataFrame repr</code> for wide <code>DataFrames</code> across multiple lines, <code>max_columns</code> is still respected, but the output will wrap-around across multiple “pages” if its width exceeds <code>display.width</code> .

continues on next page

Table 5 – continued from previous page

Option	Default	Function
display.float_format	None	The callable should accept a floating point number and return a string with the desired format of the number. This is used in some places like SeriesFormatter. See core.format.EngFormatter for an example.
display.large_repr	truncate	For DataFrames exceeding max_rows/max_cols, the repr (and HTML repr) can show a truncated table (the default), or switch to the view from df.info() (the behaviour in earlier versions of pandas). allowable settings, ['truncate', 'info']
display.latex.repr	False	Whether to produce a latex DataFrame representation for Jupyter frontends that support it.
display.latex.escape	True	Escapes special characters in DataFrames, when using the to_latex method.
display.latex.longtable	False	Specifies if the to_latex method of a DataFrame uses the longtable format.
display.latex.multiprint	True	Combines columns when using a MultiIndex
display.latex.multiprint_format	'l'	Alignment of multiprint labels
display.latex.multirow	False	Combines rows when using a MultiIndex. Centered instead of top-aligned, separated by clines.
display.max_columns	0 or 20	max_rows and max_columns are used in __repr__() methods to decide if to_string() or info() is used to render an object to a string. In case Python/IPython is running in a terminal this is set to 0 by default and pandas will correctly auto-detect the width of the terminal and switch to a smaller format in case all columns would not fit vertically. The IPython notebook, IPython qt-console, or IDLE do not run in a terminal and hence it is not possible to do correct auto-detection, in which case the default is set to 20. 'None' value means unlimited.

continues on next page

Table 5 – continued from previous page

Option	Default	Function
display.max_colwidth	50	The maximum width in characters of a column in the repr of a pandas data structure. When the column overflows, a “...” placeholder is embedded in the output. ‘None’ value means unlimited.
display.max_info_columns	100	max_info_columns is used in DataFrame.info method to decide if per column information will be printed.
display.max_info_rows	1690785	df.info() will usually show null-counts for each column. For large frames this can be quite slow. max_info_rows and max_info_cols limit this null check only to frames with smaller dimensions than specified.
display.max_rows	60	This sets the maximum number of rows pandas should output when printing out various output. For example, this value determines whether the repr() for a dataframe prints out fully or just a truncated or summary repr. ‘None’ value means unlimited.
display.min_rows	10	The numbers of rows to show in a truncated repr (when max_rows is exceeded). Ignored when max_rows is set to None or 0. When set to None, follows the value of max_rows.
display.max_seq_items	100	when pretty-printing a long sequence, no more than max_seq_items will be printed. If items are omitted, they will be denoted by the addition of “...” to the resulting string. If set to None, the number of items to be printed is unlimited.
display.memory_usage	True	This specifies if the memory usage of a DataFrame should be displayed when the df.info() method is invoked.
display.multi_sparse	True	“Sparsify” MultiIndex display (don’t display repeated elements in outer levels within groups)
display.notebook_repr_html	True	When True, IPython notebook will use html representation for pandas objects (if it is available).
display.pprint_nest_depth	3	Controls the number of nested levels to process when pretty-printing

continues on next page

Table 5 – continued from previous page

Option	Default	Function
display.precision	6	Floating point output precision in terms of number of places after the decimal, for regular formatting as well as scientific notation. Similar to numpy's <code>precision</code> print option
display.show_dimensions	truncate	Whether to print out dimensions at the end of DataFrame repr. If 'truncate' is specified, only print out the dimensions if the frame is truncated (e.g. not display all rows and/or columns)
display.width	80	Width of the display in characters. In case Python/IPython is running in a terminal this can be set to None and pandas will correctly auto-detect the width. Note that the IPython notebook, IPython qtconsole, or IDLE do not run in a terminal and hence it is not possible to correctly detect the width.
display.html.table_schema	False	Whether to publish a Table Schema representation for frontends that support it.
display.html.border	1	A <code>border=value</code> attribute is inserted in the <code><table></code> tag for the DataFrame HTML repr.
display.html.use_mathjax	True	When True, Jupyter notebook will process table contents using MathJax, rendering mathematical expressions enclosed by the dollar symbol.
display.max_dir_items	100	The number of columns from a dataframe that are added to dir. These columns can then be suggested by tab completion. 'None' value means unlimited.
io.excel.xls.writer	xlwt	The default Excel writer engine for 'xls' files. Deprecated since version 1.2.0: As <code>xlwt</code> package is no longer maintained, the <code>xlwt</code> engine will be removed in a future version of pandas. Since this is the only engine in pandas that supports writing to .xls files, this option will also be removed.
io.excel.xlsm.writer	openpyxl	The default Excel writer engine for 'xlsm' files. Available options: 'openpyxl' (the default).
io.excel.xlsx.writer	openpyxl	The default Excel writer engine for 'xlsx' files.

continues on next page

Table 5 – continued from previous page

Option	Default	Function
io.hdf.default_format	None	default format writing format, if None, then put will default to ‘fixed’ and append will default to ‘table’
io.hdf.dropna_table	True	drop ALL nan rows when appending to a table
io.parquet.engine	None	The engine to use as a default for parquet reading and writing. If None then try ‘pyarrow’ and ‘fastparquet’
io.sql.engine	None	The engine to use as a default for sql reading and writing, with SQLAlchemy as a higher level interface. If None then try ‘sqlalchemy’
mode.chained_assignment	warn	Controls SettingWithCopyWarning: ‘raise’, ‘warn’, or None. Raise an exception, warn, or no action if trying to use <i>chained assignment</i> .
mode.sim_interactive	False	Whether to simulate interactive mode for purposes of testing.
mode.use_inf_as_na	False	True means treat None, NaN, -INF, INF as NA (old way), False means None and NaN are null, but INF, -INF are not NA (new way).
compute.use_bottleneck	True	Use the bottleneck library to accelerate computation if it is installed.
compute.use_numexpr	True	Use the numexpr library to accelerate computation if it is installed.
plotting.backend	matplotlib	Change the plotting backend to a different backend than the current matplotlib one. Backends can be implemented as third-party libraries implementing the pandas plotting API. They can use other plotting libraries like Bokeh, Altair, etc.
plotting.matplotlib.register_converters	True	Register custom converters with matplotlib. Set to False to de-register.
styler.sparse.index	True	“Sparsify” MultiIndex display for rows in Styler output (don’t display repeated elements in outer levels within groups).
styler.sparse.columns	True	“Sparsify” MultiIndex display for columns in Styler output.
styler.render.repr	html	Standard output format for Styler rendered in Jupyter Notebook. Should be one of “html” or “latex”.
styler.render.max_elements	262144	Maximum number of datapoints that Styler will render trimming either rows, columns or both to fit.

continues on next page

Table 5 – continued from previous page

Option	Default	Function
styler.render.max_rows	None	Maximum number of rows that Styler will render. By default this is dynamic based on <code>max_elements</code> .
styler.render.max_columns	None	Maximum number of columns that Styler will render. By default this is dynamic based on <code>max_elements</code> .
styler.render.encoding	utf-8	Default encoding for output HTML or LaTeX files.
styler.format.formatter	None	Object to specify formatting functions to <code>Styler.format</code> .
styler.format.na_rep	None	String representation for missing data.
styler.format.precision	6	Precision to display floating point and complex numbers.
styler.format.decimal	.	String representation for decimal point separator for floating point and complex numbers.
styler.format.thousands	None	String representation for thousands separator for integers, and floating point and complex numbers.
styler.format.escape	None	Whether to escape “html” or “latex” special characters in the display representation.
styler.html.mathjax	True	If set to False will render specific CSS classes to table attributes that will prevent Mathjax from rendering in Jupyter Notebook.
styler.latex.multicolumn_align	r	Alignment of headers in a merged column due to sparsification. Can be in {“r”, “c”, “l”}.
styler.latex.multirow_align	c	Alignment of index labels in a merged row due to sparsification. Can be in {“c”, “t”, “b”}.
styler.latex.environment	None	If given will replace the default <code>\begin{table}</code> environment. If “longtable” is specified this will render with a specific “longtable” template with longtable features.
styler.latex.hrules	False	If set to True will render <code>\toprule</code> , <code>\midrule</code> , and <code>\bottomrule</code> by default.

2.22.6 Number formatting

pandas also allows you to set how numbers are displayed in the console. This option is not set through the `set_options` API.

Use the `set_eng_float_format` function to alter the floating-point formatting of pandas objects to produce a particular format.

For instance:

```
In [87]: import numpy as np

In [88]: pd.set_eng_float_format(accuracy=3, use_eng_prefix=True)

In [89]: s = pd.Series(np.random.randn(5), index=["a", "b", "c", "d", "e"])

In [90]: s / 1.0e3
Out[90]:
a    303.638u
b   -721.084u
c   -622.696u
d    648.250u
e    -1.945m
dtype: float64

In [91]: s / 1.0e6
Out[91]:
a    303.638n
b   -721.084n
c   -622.696n
d    648.250n
e    -1.945u
dtype: float64
```

To round floats on a case-by-case basis, you can also use `round()` and `round()`.

2.22.7 Unicode formatting

Warning: Enabling this option will affect the performance for printing of DataFrame and Series (about 2 times slower). Use only when it is actually required.

Some East Asian countries use Unicode characters whose width corresponds to two Latin characters. If a DataFrame or Series contains these characters, the default output mode may not align them properly.

Note: Screen captures are attached for each output to show the actual results.

```
In [92]: df = pd.DataFrame({"": ["UK", ""],"": ["Alice", ""]})

In [93]: df
Out[93]:
```

(continues on next page)

(continued from previous page)

```
0  UK  Alice
1
```

```
>>> df = pd.DataFrame({u'国籍': ['UK', u'日本'], u'名前': ['Alice', u'しのぶ']})
>>> df
   名前 国籍
0  Alice  UK
1    しのぶ  日本
```

Enabling `display.unicode.east_asian_width` allows pandas to check each character's "East Asian Width" property. These characters can be aligned properly by setting this option to True. However, this will result in longer render times than the standard `len` function.

```
In [94]: pd.set_option("display.unicode.east_asian_width", True)
```

```
In [95]: df
Out[95]:
```

```
0      UK  Alice
1
```

```
>>> pd.set_option('display.unicode.east_asian_width', True)
>>> df
   名前 国籍
0  Alice  UK
1    しのぶ  日本
```

In addition, Unicode characters whose width is "Ambiguous" can either be 1 or 2 characters wide depending on the terminal setting or encoding. The option `display.unicode.ambiguous_as_wide` can be used to handle the ambiguity.

By default, an "Ambiguous" character's width, such as "¡" (inverted exclamation) in the example below, is taken to be 1.

```
In [96]: df = pd.DataFrame({"a": ["xxx", "¡¡"], "b": ["yyy", "¡¡"]})
```

```
In [97]: df
Out[97]:
```

```
   a     b
0  xxx   yyy
1    ¡¡    ¡¡
```

```
>>> df = pd.DataFrame({'a': ['xxx', u'¡¡'], 'b': ['yyy', u'¡¡']})
>>> df
   a     b
0  xxx   yyy
1    ¡¡    ¡¡
```

Enabling `display.unicode.ambiguous_as_wide` makes pandas interpret these characters' widths to be 2. (Note that this option will only be effective when `display.unicode.east_asian_width` is enabled.)

However, setting this option incorrectly for your terminal will cause these characters to be aligned incorrectly:

```
In [98]: pd.set_option("display.unicode.ambiguous_as_wide", True)
```

```
In [99]: df
```

(continues on next page)

(continued from previous page)

Out[99]:

```
a      b  
0    xxx    yyy  
1    ii     ii
```

```
>>> pd.set_option('display.unicode.ambiguous_as_wide', True)  
>>> df  
          a      b  
0    xxx    yyy  
1    ii     ii
```

2.22.8 Table schema display

DataFrame and Series will publish a Table Schema representation by default. False by default, this can be enabled globally with the `display.html.table_schema` option:

```
In [100]: pd.set_option("display.html.table_schema", True)
```

Only `'display.max_rows'` are serialized and published.

2.23 Enhancing performance

In this part of the tutorial, we will investigate how to speed up certain functions operating on pandas DataFrames using three different techniques: Cython, Numba and `pandas.eval()`. We will see a speed improvement of ~200 when we use Cython and Numba on a test function operating row-wise on the DataFrame. Using `pandas.eval()` we will speed up a sum by an order of ~2.

Note: In addition to following the steps in this tutorial, users interested in enhancing performance are highly encouraged to install the [recommended dependencies](#) for pandas. These dependencies are often not installed by default, but will offer speed improvements if present.

2.23.1 Cython (writing C extensions for pandas)

For many use cases writing pandas in pure Python and NumPy is sufficient. In some computationally heavy applications however, it can be possible to achieve sizable speed-ups by offloading work to `cython`.

This tutorial assumes you have refactored as much as possible in Python, for example by trying to remove for-loops and making use of NumPy vectorization. It's always worth optimising in Python first.

This tutorial walks through a “typical” process of cythonizing a slow computation. We use an example from the [Cython documentation](#) but in the context of pandas. Our final cythonized solution is around 100 times faster than the pure Python solution.

Pure Python

We have a DataFrame to which we want to apply a function row-wise.

```
In [1]: df = pd.DataFrame(
...:     {
...:         "a": np.random.randn(1000),
...:         "b": np.random.randn(1000),
...:         "N": np.random.randint(100, 1000, (1000)),
...:         "x": "x",
...:     }
...: )
...:

In [2]: df
Out[2]:
      a      b      N  x
0   0.469112 -0.218470  585  x
1  -0.282863 -0.061645  841  x
2  -1.509059 -0.723780  251  x
3  -1.135632  0.551225  972  x
4   1.212112 -0.497767  181  x
...
995 -1.512743  0.874737  374  x
996  0.933753  1.120790  246  x
997 -0.308013  0.198768  157  x
998 -0.079915  1.757555  977  x
999 -1.010589 -1.115680  770  x

[1000 rows x 4 columns]
```

Here's the function in pure Python:

```
In [3]: def f(x):
...:     return x * (x - 1)
...:

In [4]: def integrate_f(a, b, N):
...:     s = 0
...:     dx = (b - a) / N
...:     for i in range(N):
...:         s += f(a + i * dx)
...:     return s * dx
...:
```

We achieve our result by using `apply` (row-wise):

```
In [7]: %timeit df.apply(lambda x: integrate_f(x["a"], x["b"], x["N"]), axis=1)
10 loops, best of 3: 174 ms per loop
```

But clearly this isn't fast enough for us. Let's take a look and see where the time is spent during this operation (limited to the most time consuming four calls) using the `prun ipython` magic function:

```
In [5]: %prun -l 4 df.apply(lambda x: integrate_f(x["a"], x["b"], x["N"]), axis=1) #_  
noqa E999  
638348 function calls (638330 primitive calls) in 0.309 seconds  
  
Ordered by: internal time  
List reduced from 228 to 4 due to restriction <4>  
  
ncalls  tottime  percall  cumtime  percall  filename:lineno(function)  
    1000    0.155    0.000    0.225    0.000 <ipython-input-4-c2a74e076cf0>:1(integrate_  
_f)  
  552423    0.070    0.000    0.070    0.000 <ipython-input-3-c138bdd570e3>:1(f)  
    3000    0.009    0.000    0.047    0.000 series.py:943(__getitem__)  
    3000    0.006    0.000    0.030    0.000 series.py:1052(__get_value)
```

By far the majority of time is spent inside either `integrate_f` or `f`, hence we'll concentrate our efforts cythonizing these two functions.

Plain Cython

First we're going to need to import the Cython magic function to IPython:

```
In [6]: %load_ext Cython
```

Now, let's simply copy our functions over to Cython as is (the suffix is here to distinguish between function versions):

```
In [7]: %%cython  
....: def f_plain(x):  
....:     return x * (x - 1)  
....: def integrate_f_plain(a, b, N):  
....:     s = 0  
....:     dx = (b - a) / N  
....:     for i in range(N):  
....:         s += f_plain(a + i * dx)  
....:     return s * dx
```

Note: If you're having trouble pasting the above into your ipython, you may need to be using bleeding edge IPython for paste to play well with cell magics.

```
In [4]: %timeit df.apply(lambda x: integrate_f_plain(x["a"], x["b"], x["N"]), axis=1)  
10 loops, best of 3: 85.5 ms per loop
```

Already this has shaved a third off, not too bad for a simple copy and paste.

Adding type

We get another huge improvement simply by providing type information:

```
In [8]: %%cython
....: cdef double f_typed(double x) except? -2:
....:     return x * (x - 1)
....: cpdef double integrate_f_typed(double a, double b, int N):
....:     cdef int i
....:     cdef double s, dx
....:     s = 0
....:     dx = (b - a) / N
....:     for i in range(N):
....:         s += f_typed(a + i * dx)
....:     return s * dx
....:
```

```
In [4]: %timeit df.apply(lambda x: integrate_f_typed(x["a"], x["b"], x["N"]), axis=1)
10 loops, best of 3: 20.3 ms per loop
```

Now, we're talking! It's now over ten times faster than the original Python implementation, and we haven't *really* modified the code. Let's have another look at what's eating up time:

```
In [9]: %prun -l 4 df.apply(lambda x: integrate_f_typed(x["a"], x["b"], x["N"]), axis=1)
85918 function calls (85900 primitive calls) in 0.052 seconds

Ordered by: internal time
List reduced from 221 to 4 due to restriction <4>

ncalls  tottime  percall  cumtime  percall filename:lineno(function)
    3000    0.006    0.000    0.031    0.000 series.py:943(__getitem__)
    3000    0.004    0.000    0.018    0.000 series.py:1052(__get_value)
   16189    0.003    0.000    0.004    0.000 {built-in method builtins.isinstance}
    3000    0.003    0.000    0.005    0.000 base.py:5646(__get_values_for_loc)
```

Using ndarray

It's calling `series...` a lot! It's creating a Series from each row, and get-ting from both the index and the series (three times for each row). Function calls are expensive in Python, so maybe we could minimize these by cythonizing the apply part.

Note: We are now passing ndarrays into the Cython function, fortunately Cython plays very nicely with NumPy.

```
In [10]: %%cython
....: cimport numpy as np
....: import numpy as np
....: cdef double f_typed(double x) except? -2:
....:     return x * (x - 1)
....: cpdef double integrate_f_typed(double a, double b, int N):
....:     cdef int i
....:     cdef double s, dx
```

(continues on next page)

(continued from previous page)

```
s = 0
dx = (b - a) / N
for i in range(N):
    s += f_typed(a + i * dx)
return s * dx
cpdef np.ndarray[double] apply_integrate_f(np.ndarray col_a, np.ndarray col_b,
                                            np.ndarray col_N):
    assert (col_a.dtype == np.float_
           and col_b.dtype == np.float_ and col_N.dtype == np.int_)
    cdef Py_ssize_t i, n = len(col_N)
    assert (len(col_a) == len(col_b) == n)
    cdef np.ndarray[double] res = np.empty(n)
    for i in range(len(col_a)):
        res[i] = integrate_f_typed(col_a[i], col_b[i], col_N[i])
    return res
```

The implementation is simple, it creates an array of zeros and loops over the rows, applying our `integrate_f_typed`, and putting this in the `zeros` array.

Warning: You can **not** pass a Series directly as a ndarray typed parameter to a Cython function. Instead pass the actual ndarray using the [Series.to_numpy\(\)](#). The reason is that the Cython definition is specific to an ndarray and not the passed Series.

So, do not do this:

```
apply_integrate_f(df["a"], df["b"], df["N"])
```

But rather, use `Series.to_numpy()` to get the underlying ndarray:

```
apply_integrate_f(df["a"].to_numpy(), df["b"].to_numpy(), df["N"].to_numpy())
```

Note: Loops like this would be *extremely* slow in Python, but in Cython looping over NumPy arrays is *fast*.

```
In [4]: %timeit apply_integrate_f(df["a"].to_numpy(), df["b"].to_numpy(), df["N"].to_numpy())
1000 loops. best of 3: 1.25 ms per loop
```

We've gotten another big improvement. Let's check again where the time is spent:

```
In [11]: %prun -l 4 apply_integrate_f(df["a"].to_numpy(), df["b"].to_numpy(), df["N"].to_numpy())
          200 function calls in 0.002 seconds

Ordered by: internal time
List reduced from 53 to 4 due to restriction <4>

      ncalls  tottime  percall  cumtime  percall filename:lineno(function)
          1    0.001    0.001    0.001    0.001 {built-in method _cython_magic_
→ddc107c474f1147882a8a0afef7a24e2.apply_integrate_f}
```

(continues on next page)

(continued from previous page)

3	0.000	0.000	0.000	0.000	frame.py:3463(__getitem__)
3	0.000	0.000	0.000	0.000	managers.py:1016(iget)
1	0.000	0.000	0.002	0.002	{built-in method builtins.exec}

As one might expect, the majority of the time is now spent in `apply_integrate_f`, so if we wanted to make anymore efficiencies we must continue to concentrate our efforts here.

More advanced techniques

There is still hope for improvement. Here's an example of using some more advanced Cython techniques:

```
In [12]: %%cython
....: cimport cython
....: cimport numpy as np
....: import numpy as np
....: cdef double f_typed(double x) except? -2:
....:     return x * (x - 1)
....: cpdef double integrate_f_typed(double a, double b, int N):
....:     cdef int i
....:     cdef double s, dx
....:     s = 0
....:     dx = (b - a) / N
....:     for i in range(N):
....:         s += f_typed(a + i * dx)
....:     return s * dx
....: #cython.boundscheck(False)
....: #cython.wraparound(False)
....: cpdef np.ndarray[double] apply_integrate_f_wrap(np.ndarray[double] col_a,
....:                                                 np.ndarray[double] col_b,
....:                                                 np.ndarray[int] col_N):
....:     cdef int i, n = len(col_N)
....:     assert len(col_a) == len(col_b) == n
....:     cdef np.ndarray[double] res = np.empty(n)
....:     for i in range(n):
....:         res[i] = integrate_f_typed(col_a[i], col_b[i], col_N[i])
....:     return res
```

```
In [4]: %timeit apply_integrate_f_wrap(df["a"].to_numpy(), df["b"].to_numpy(), df["N"].to_numpy())
1000 loops, best of 3: 987 us per loop
```

Even faster, with the caveat that a bug in our Cython code (an off-by-one error, for example) might cause a segfault because memory access isn't checked. For more about `boundscheck` and `wraparound`, see the Cython docs on [compiler directives](#).

2.23.2 Numba (JIT compilation)

An alternative to statically compiling Cython code is to use a dynamic just-in-time (JIT) compiler with [Numba](#).

Numba allows you to write a pure Python function which can be JIT compiled to native machine instructions, similar in performance to C, C++ and Fortran, by decorating your function with `@jit`.

Numba works by generating optimized machine code using the LLVM compiler infrastructure at import time, runtime, or statically (using the included `pycc` tool). Numba supports compilation of Python to run on either CPU or GPU hardware and is designed to integrate with the Python scientific software stack.

Note: The `@jit` compilation will add overhead to the runtime of the function, so performance benefits may not be realized especially when using small data sets. Consider [caching](#) your function to avoid compilation overhead each time your function is run.

Numba can be used in 2 ways with pandas:

1. Specify the `engine="numba"` keyword in select pandas methods
2. Define your own Python function decorated with `@jit` and pass the underlying NumPy array of [Series](#) or [Dataframe](#) (using `to_numpy()`) into the function

pandas Numba Engine

If Numba is installed, one can specify `engine="numba"` in select pandas methods to execute the method using Numba. Methods that support `engine="numba"` will also have an `engine_kwarg`s keyword that accepts a dictionary that allows one to specify "nogil", "nopython" and "parallel" keys with boolean values to pass into the `@jit` decorator. If `engine_kwarg`s is not specified, it defaults to `{"nogil": False, "nopython": True, "parallel": False}` unless otherwise specified.

In terms of performance, **the first time a function is run using the Numba engine will be slow** as Numba will have some function compilation overhead. However, the JIT compiled functions are cached, and subsequent calls will be fast. In general, the Numba engine is performant with a larger amount of data points (e.g. 1+ million).

```
In [1]: data = pd.Series(range(1_000_000)) # noqa: E225
In [2]: roll = data.rolling(10)
In [3]: def f(x):
...:     return np.sum(x) + 5
# Run the first time, compilation time will affect performance
In [4]: %timeit -r 1 -n 1 roll.apply(f, engine='numba', raw=True)
1.23 s ± 0 ns per loop (mean ± std. dev. of 1 run, 1 loop each)
# Function is cached and performance will improve
In [5]: %timeit roll.apply(f, engine='numba', raw=True)
188 ms ± 1.93 ms per loop (mean ± std. dev. of 7 runs, 10 loops each)

In [6]: %timeit roll.apply(f, engine='cython', raw=True)
3.92 s ± 59 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)
```

Custom Function Examples

A custom Python function decorated with `@jit` can be used with pandas objects by passing their NumPy array representations with `to_numpy()`.

```
import numba

@numba.jit
def f_plain(x):
    return x * (x - 1)

@numba.jit
def integrate_f_numba(a, b, N):
    s = 0
    dx = (b - a) / N
    for i in range(N):
        s += f_plain(a + i * dx)
    return s * dx

@numba.jit
def apply_integrate_f_numba(col_a, col_b, col_N):
    n = len(col_N)
    result = np.empty(n, dtype="float64")
    assert len(col_a) == len(col_b) == n
    for i in range(n):
        result[i] = integrate_f_numba(col_a[i], col_b[i], col_N[i])
    return result

def compute_numba(df):
    result = apply_integrate_f_numba(
        df["a"].to_numpy(), df["b"].to_numpy(), df["N"].to_numpy()
    )
    return pd.Series(result, index=df.index, name="result")
```

```
In [4]: %timeit compute_numba(df)
1000 loops, best of 3: 798 us per loop
```

In this example, using Numba was faster than Cython.

Numba can also be used to write vectorized functions that do not require the user to explicitly loop over the observations of a vector; a vectorized function will be applied to each row automatically. Consider the following example of doubling each observation:

```
import numba

def double_every_value_nonumba(x):
    return x * 2
```

(continues on next page)

(continued from previous page)

```
@numba.vectorize
def double_every_value_withnumba(x): # noqa E501
    return x * 2

# Custom function without numba
In [5]: %timeit df["col1_doubled"] = df["a"].apply(double_every_value_nonumba) # noqa_
          E501
1000 loops, best of 3: 797 us per loop

# Standard implementation (faster than a custom function)
In [6]: %timeit df["col1_doubled"] = df["a"] * 2
1000 loops, best of 3: 233 us per loop

# Custom function with numba
In [7]: %timeit df["col1_doubled"] = double_every_value_withnumba(df["a"].to_numpy())
1000 loops, best of 3: 145 us per loop
```

Caveats

Numba is best at accelerating functions that apply numerical functions to NumPy arrays. If you try to `@jit` a function that contains unsupported Python or NumPy code, compilation will revert `object mode` which will mostly likely not speed up your function. If you would prefer that Numba throw an error if it cannot compile a function in a way that speeds up your code, pass Numba the argument `nopython=True` (e.g. `@jit(nopython=True)`). For more on troubleshooting Numba modes, see the [Numba troubleshooting page](#).

Using `parallel=True` (e.g. `@jit(parallel=True)`) may result in a SIGABRT if the threading layer leads to unsafe behavior. You can first [specify a safe threading layer](#) before running a JIT function with `parallel=True`.

Generally if you encounter a segfault (SIGSEGV) while using Numba, please report the issue to the [Numba issue tracker](#).

2.23.3 Expression evaluation via eval()

The top-level function `pandas.eval()` implements expression evaluation of `Series` and `DataFrame` objects.

Note: To benefit from using `eval()` you need to install `numexpr`. See the [recommended dependencies section](#) for more details.

The point of using `eval()` for expression evaluation rather than plain Python is two-fold: 1) large `DataFrame` objects are evaluated more efficiently and 2) large arithmetic and boolean expressions are evaluated all at once by the underlying engine (by default `numexpr` is used for evaluation).

Note: You should not use `eval()` for simple expressions or for expressions involving small DataFrames. In fact, `eval()` is many orders of magnitude slower for smaller expressions/objects than plain ol' Python. A good rule of thumb is to only use `eval()` when you have a `DataFrame` with more than 10,000 rows.

`eval()` supports all arithmetic expressions supported by the engine in addition to some extensions available only in pandas.

Note: The larger the frame and the larger the expression the more speedup you will see from using `eval()`.

Supported syntax

These operations are supported by `pandas.eval()`:

- Arithmetic operations except for the left shift (<<) and right shift (>>) operators, e.g., `df + 2 * pi / s ** 4 % 42 - the_golden_ratio`
- Comparison operations, including chained comparisons, e.g., `2 < df < df2`
- Boolean operations, e.g., `df < df2` and `df3 < df4` or `not df_bool`
- `list` and `tuple` literals, e.g., `[1, 2]` or `(1, 2)`
- Attribute access, e.g., `df.a`
- Subscript expressions, e.g., `df[0]`
- Simple variable evaluation, e.g., `pd.eval("df")` (this is not very useful)
- Math functions: `sin`, `cos`, `exp`, `log`, `expm1`, `log1p`, `sqrt`, `sinh`, `cosh`, `tanh`, `arcsin`, `arccos`, `arctan`, `arccosh`, `arcsinh`, `arctanh`, `abs`, `arctan2` and `log10`.

This Python syntax is **not** allowed:

- Expressions
 - Function calls other than math functions.
 - `is/is not` operations
 - `if` expressions
 - `lambda` expressions
 - `list/set/dict comprehensions`
 - Literal `dict` and `set` expressions
 - `yield` expressions
 - Generator expressions
 - Boolean expressions consisting of only scalar values
- Statements
 - Neither `simple` nor `compound` statements are allowed. This includes things like `for`, `while`, and `if`.

eval() examples

`pandas.eval()` works well with expressions containing large arrays.

First let's create a few decent-sized arrays to play with:

```
In [13]: nrows, ncols = 20000, 100
In [14]: df1, df2, df3, df4 = [pd.DataFrame(np.random.randn(nrows, ncols)) for _ in
                           range(4)]
```

Now let's compare adding them together using plain ol' Python versus `eval()`:

```
In [15]: %timeit df1 + df2 + df3 + df4
8.34 ms +- 147 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

```
In [16]: %timeit pd.eval("df1 + df2 + df3 + df4")
5.71 ms +- 121 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

Now let's do the same thing but with comparisons:

```
In [17]: %timeit (df1 > 0) & (df2 > 0) & (df3 > 0) & (df4 > 0)
7.47 ms +- 199 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

```
In [18]: %timeit pd.eval("(df1 > 0) & (df2 > 0) & (df3 > 0) & (df4 > 0)")
6.64 ms +- 62.7 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

`eval()` also works with unaligned pandas objects:

```
In [19]: s = pd.Series(np.random.randn(50))
```

```
In [20]: %timeit df1 + df2 + df3 + df4 + s
23.8 ms +- 697 us per loop (mean +- std. dev. of 7 runs, 10 loops each)
```

```
In [21]: %timeit pd.eval("df1 + df2 + df3 + df4 + s")
6.3 ms +- 67.3 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

Note: Operations such as

```
1 and 2 # would parse to 1 & 2, but should evaluate to 2
3 or 4 # would parse to 3 | 4, but should evaluate to 3
~1 # this is okay, but slower when using eval
```

should be performed in Python. An exception will be raised if you try to perform any boolean/bitwise operations with scalar operands that are not of type `bool` or `np.bool_`. Again, you should perform these kinds of operations in plain Python.

The DataFrame.eval method

In addition to the top level `pandas.eval()` function you can also evaluate an expression in the “context” of a `DataFrame`.

```
In [22]: df = pd.DataFrame(np.random.randn(5, 2), columns=["a", "b"])
```

```
In [23]: df.eval("a + b")
```

```
Out[23]:
```

```
0    -0.246747
1     0.867786
2    -1.626063
3    -1.134978
4    -1.027798
dtype: float64
```

Any expression that is a valid `pandas.eval()` expression is also a valid `DataFrame.eval()` expression, with the added benefit that you don't have to prefix the name of the `DataFrame` to the column(s) you're interested in evaluating.

In addition, you can perform assignment of columns within an expression. This allows for *formulaic evaluation*. The assignment target can be a new column name or an existing column name, and it must be a valid Python identifier.

The `inplace` keyword determines whether this assignment will be performed on the original DataFrame or return a copy with the new column.

```
In [24]: df = pd.DataFrame(dict(a=range(5), b=range(5, 10)))
```

```
In [25]: df.eval("c = a + b", inplace=True)
```

```
In [26]: df.eval("d = a + b + c", inplace=True)
```

```
In [27]: df.eval("a = 1", inplace=True)
```

```
In [28]: df
```

```
Out[28]:
```

	a	b	c	d
0	1	5	5	10
1	1	6	7	14
2	1	7	9	18
3	1	8	11	22
4	1	9	13	26

When `inplace` is set to `False`, the default, a copy of the DataFrame with the new or modified columns is returned and the original frame is unchanged.

```
In [29]: df
```

```
Out[29]:
```

	a	b	c	d
0	1	5	5	10
1	1	6	7	14
2	1	7	9	18
3	1	8	11	22
4	1	9	13	26

```
In [30]: df.eval("e = a - c", inplace=False)
```

```
Out[30]:
```

	a	b	c	d	e
0	1	5	5	10	-4
1	1	6	7	14	-6
2	1	7	9	18	-8
3	1	8	11	22	-10
4	1	9	13	26	-12

```
In [31]: df
```

```
Out[31]:
```

	a	b	c	d
0	1	5	5	10
1	1	6	7	14
2	1	7	9	18
3	1	8	11	22
4	1	9	13	26

As a convenience, multiple assignments can be performed by using a multi-line string.

```
In [32]: df.eval(  
.....    """  
.....: c = a + b  
.....: d = a + b + c  
.....: a = 1"""  
.....:     inplace=False,  
.....: )  
.....:  
Out[32]:  
   a   b   c   d  
0  1   5   6  12  
1  1   6   7  14  
2  1   7   8  16  
3  1   8   9  18  
4  1   9  10  20
```

The equivalent in standard Python would be

```
In [33]: df = pd.DataFrame(dict(a=range(5), b=range(5, 10)))  
  
In [34]: df["c"] = df["a"] + df["b"]  
  
In [35]: df["d"] = df["a"] + df["b"] + df["c"]  
  
In [36]: df["a"] = 1  
  
In [37]: df  
Out[37]:  
   a   b   c   d  
0  1   5   6  10  
1  1   6   7  14  
2  1   7   8  18  
3  1   8  11  22  
4  1   9  13  26
```

The query method has a `inplace` keyword which determines whether the query modifies the original frame.

```
In [38]: df = pd.DataFrame(dict(a=range(5), b=range(5, 10)))  
  
In [39]: df.query("a > 2")  
Out[39]:  
   a   b  
3  3   8  
4  4   9  
  
In [40]: df.query("a > 2", inplace=True)  
  
In [41]: df  
Out[41]:  
   a   b  
3  3   8  
4  4   9
```

Local variables

You must *explicitly reference* any local variable that you want to use in an expression by placing the @ character in front of the name. For example,

```
In [42]: df = pd.DataFrame(np.random.randn(5, 2), columns=list("ab"))
```

```
In [43]: newcol = np.random.randn(len(df))
```

```
In [44]: df.eval("b + @newcol")
```

```
Out[44]:
```

```
0 -0.173926
1 2.493083
2 -0.881831
3 -0.691045
4 1.334703
dtype: float64
```

```
In [45]: df.query("b < @newcol")
```

```
Out[45]:
```

	a	b
0	0.863987	-0.115998
2	-2.621419	-1.297879

If you don't prefix the local variable with @, pandas will raise an exception telling you the variable is undefined.

When using `DataFrame.eval()` and `DataFrame.query()`, this allows you to have a local variable and a `DataFrame` column with the same name in an expression.

```
In [46]: a = np.random.randn()
```

```
In [47]: df.query("@a < a")
```

```
Out[47]:
```

	a	b
0	0.863987	-0.115998

```
In [48]: df.loc[a < df["a"]] # same as the previous expression
```

```
Out[48]:
```

	a	b
0	0.863987	-0.115998

With `pandas.eval()` you cannot use the @ prefix *at all*, because it isn't defined in that context. pandas will let you know this if you try to use @ in a top-level call to `pandas.eval()`. For example,

```
In [49]: a, b = 1, 2
```

```
In [50]: pd.eval("@a + b")
```

```
Traceback (most recent call last):

pd.eval("@a + b")

File /pandas/pandas/core/computation/eval.py:339 in eval
    _check_for_locals(expr, level, parser)

File /pandas/pandas/core/computation/eval.py:163 in _check_for_locals
    raise SyntaxError(msg)

File <string>
SyntaxError: The '@' prefix is not allowed in top-level eval calls.
please refer to your variables by name without the '@' prefix.
```

In this case, you should simply refer to the variables like you would in standard Python.

```
In [51]: pd.eval("a + b")
Out[51]: 3
```

pandas.eval() parsers

There are two different parsers and two different engines you can use as the backend.

The default 'pandas' parser allows a more intuitive syntax for expressing query-like operations (comparisons, conjunctions and disjunctions). In particular, the precedence of the & and | operators is made equal to the precedence of the corresponding boolean operations and and or.

For example, the above conjunction can be written without parentheses. Alternatively, you can use the 'python' parser to enforce strict Python semantics.

```
In [52]: expr = "(df1 > 0) & (df2 > 0) & (df3 > 0) & (df4 > 0)"

In [53]: x = pd.eval(expr, parser="python")

In [54]: expr_no_parens = "df1 > 0 & df2 > 0 & df3 > 0 & df4 > 0"

In [55]: y = pd.eval(expr_no_parens, parser="pandas")

In [56]: np.all(x == y)
Out[56]: True
```

The same expression can be “anded” together with the word `and` as well:

```
In [57]: expr = "(df1 > 0) & (df2 > 0) & (df3 > 0) & (df4 > 0)"

In [58]: x = pd.eval(expr, parser="python")

In [59]: expr_with_and = "df1 > 0 and df2 > 0 and df3 > 0 and df4 > 0"

In [60]: y = pd.eval(expr_with_and, parser="pandas")

In [61]: np.all(x == y)
Out[61]: True
```

The `and` and `or` operators here have the same precedence that they would in vanilla Python.

pandas.eval() backends

There's also the option to make `eval()` operate identical to plain ol' Python.

Note: Using the 'python' engine is generally *not* useful, except for testing other evaluation engines against it. You will achieve **no** performance benefits using `eval()` with `engine='python'` and in fact may incur a performance hit.

You can see this by using `pandas.eval()` with the 'python' engine. It is a bit slower (not by much) than evaluating the same expression in Python

```
In [62]: %timeit df1 + df2 + df3 + df4
8.31 ms +- 544 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

```
In [63]: %timeit pd.eval("df1 + df2 + df3 + df4", engine="python")
9.31 ms +- 354 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

pandas.eval() performance

`eval()` is intended to speed up certain kinds of operations. In particular, those operations involving complex expressions with large `DataFrame/Series` objects should see a significant performance benefit. Here is a plot showing the running time of `pandas.eval()` as function of the size of the frame involved in the computation. The two lines are two different engines.

Note: Operations with smallish objects (around 15k-20k rows) are faster using plain Python:

This plot was created using a DataFrame with 3 columns each containing floating point values generated using numpy.random.rand().

Technical minutia regarding expression evaluation

Expressions that would result in an object dtype or involve datetime operations (because of NaT) must be evaluated in Python space. The main reason for this behavior is to maintain backwards compatibility with versions of NumPy < 1.7. In those versions of NumPy a call to ndarray.astype(str) will truncate any strings that are more than 60 characters in length. Second, we can't pass object arrays to numexpr thus string comparisons must be evaluated in Python space.

The upshot is that this *only* applies to object-dtype expressions. So, if you have an expression—for example

```
In [64]: df = pd.DataFrame(  
.....:     {"strings": np.repeat(list("cba"), 3), "nums": np.repeat(range(3), 3)}  
.....:  
.....:  
  
In [65]: df  
Out[65]:  
   strings  nums  
0        c    0  
1        c    0  
2        c    0  
3        b    1  
4        b    1  
5        b    1  
6        a    2  
7        a    2  
8        a    2  
  
In [66]: df.query("strings == 'a' and nums == 1")  
Out[66]:
```

(continues on next page)

(continued from previous page)

```
Empty DataFrame
Columns: [strings, nums]
Index: []
```

the numeric part of the comparison (`nums == 1`) will be evaluated by `numexpr`.

In general, `DataFrame.query()`/`pandas.eval()` will evaluate the subexpressions that *can* be evaluated by `numexpr` and those that must be evaluated in Python space transparently to the user. This is done by inferring the result type of an expression from its arguments and operators.

2.24 Scaling to large datasets

pandas provides data structures for in-memory analytics, which makes using pandas to analyze datasets that are larger than memory datasets somewhat tricky. Even datasets that are a sizable fraction of memory become unwieldy, as some pandas operations need to make intermediate copies.

This document provides a few recommendations for scaling your analysis to larger datasets. It's a complement to *Enhancing performance*, which focuses on speeding up analysis for datasets that fit in memory.

But first, it's worth considering *not using pandas*. pandas isn't the right tool for all situations. If you're working with very large datasets and a tool like PostgreSQL fits your needs, then you should probably be using that. Assuming you want or need the expressiveness and power of pandas, let's carry on.

```
In [1]: import pandas as pd
```

```
In [2]: import numpy as np
```

2.24.1 Load less data

Suppose our raw dataset on disk has many columns:

		id_0	name_0	x_0	y_0	id_1	name_1	x_1	...
↳ name_8	x_8	y_8	id_9	name_9	x_9	y_9

```

[525601 rows x 40 columns]

To load the columns we want, we have two options. Option 1 loads in all the data and then filters to what we need.

```
In [3]: columns = ["id_0", "name_0", "x_0", "y_0"]
```

```
In [4]: pd.read_parquet("timeseries_wide.parquet")[columns]
```

```
Out[4]:
```

	id_0	name_0	x_0	y_0
timestamp				
2000-01-01 00:00:00	1015	Michael	-0.399453	0.095427
2000-01-01 00:01:00	969	Patricia	0.650773	-0.874275
2000-01-01 00:02:00	1016	Victor	-0.721465	-0.584710
2000-01-01 00:03:00	939	Alice	-0.746004	-0.908008
2000-01-01 00:04:00	1017	Dan	0.919451	-0.803504
...
2000-12-30 23:56:00	999	Tim	0.162578	0.512817
2000-12-30 23:57:00	970	Laura	-0.433586	-0.600289
2000-12-30 23:58:00	1065	Edith	0.232211	-0.454540
2000-12-30 23:59:00	1019	Ingrid	0.322208	-0.615974
2000-12-31 00:00:00	937	Ursula	-0.906523	0.943178

[525601 rows x 4 columns]

Option 2 only loads the columns we request.

```
In [5]: pd.read_parquet("timeseries_wide.parquet", columns=columns)
```

```
Out[5]:
```

	id_0	name_0	x_0	y_0
timestamp				
2000-01-01 00:00:00	1015	Michael	-0.399453	0.095427
2000-01-01 00:01:00	969	Patricia	0.650773	-0.874275
2000-01-01 00:02:00	1016	Victor	-0.721465	-0.584710
2000-01-01 00:03:00	939	Alice	-0.746004	-0.908008
2000-01-01 00:04:00	1017	Dan	0.919451	-0.803504
...
2000-12-30 23:56:00	999	Tim	0.162578	0.512817
2000-12-30 23:57:00	970	Laura	-0.433586	-0.600289
2000-12-30 23:58:00	1065	Edith	0.232211	-0.454540
2000-12-30 23:59:00	1019	Ingrid	0.322208	-0.615974
2000-12-31 00:00:00	937	Ursula	-0.906523	0.943178

[525601 rows x 4 columns]

If we were to measure the memory usage of the two calls, we'd see that specifying `columns` uses about 1/10th the memory in this case.

With `pandas.read_csv()`, you can specify `usecols` to limit the columns read into memory. Not all file formats that can be read by pandas provide an option to read a subset of columns.

2.24.2 Use efficient datatypes

The default pandas data types are not the most memory efficient. This is especially true for text data columns with relatively few unique values (commonly referred to as “low-cardinality” data). By using more efficient data types, you can store larger datasets in memory.

```
In [6]: ts = pd.read_parquet("timeseries.parquet")
```

```
In [7]: ts
```

```
Out[7]:
```

	id	name	x	y
timestamp				
2000-01-01 00:00:00	1029	Michael	0.278837	0.247932
2000-01-01 00:00:30	1010	Patricia	0.077144	0.490260
2000-01-01 00:01:00	1001	Victor	0.214525	0.258635
2000-01-01 00:01:30	1018	Alice	-0.646866	0.822104
2000-01-01 00:02:00	991	Dan	0.902389	0.466665
...
2000-12-30 23:58:00	992	Sarah	0.721155	0.944118
2000-12-30 23:58:30	1007	Ursula	0.409277	0.133227
2000-12-30 23:59:00	1009	Hannah	-0.452802	0.184318
2000-12-30 23:59:30	978	Kevin	-0.904728	-0.179146
2000-12-31 00:00:00	973	Ingrid	-0.370763	-0.794667

```
[1051201 rows x 4 columns]
```

Now, let’s inspect the data types and memory usage to see where we should focus our attention.

```
In [8]: ts.dtypes
```

```
Out[8]:
```

id	int64
name	object
x	float64
y	float64
dtype:	object

```
In [9]: ts.memory_usage(deep=True) # memory usage in bytes
```

```
Out[9]:
```

Index	8409608
id	8409608
name	65537768
x	8409608
y	8409608
dtype:	int64

The `name` column is taking up much more memory than any other. It has just a few unique values, so it’s a good candidate for converting to a `Categorical`. With a `Categorical`, we store each unique name once and use space-efficient integers to know which specific name is used in each row.

```
In [10]: ts2 = ts.copy()
```

```
In [11]: ts2["name"] = ts2["name"].astype("category")
```

(continues on next page)

(continued from previous page)

```
In [12]: ts2.memory_usage(deep=True)
```

```
Out[12]:
```

```
Index    8409608
id      8409608
name    1053894
x       8409608
y       8409608
dtype: int64
```

We can go a bit further and downcast the numeric columns to their smallest types using `pandas.to_numeric()`.

```
In [13]: ts2["id"] = pd.to_numeric(ts2["id"], downcast="unsigned")
```

```
In [14]: ts2[["x", "y"]] = ts2[["x", "y"]].apply(pd.to_numeric, downcast="float")
```

```
In [15]: ts2.dtypes
```

```
Out[15]:
```

```
id        uint16
name     category
x        float32
y        float32
dtype: object
```

```
In [16]: ts2.memory_usage(deep=True)
```

```
Out[16]:
```

```
Index    8409608
id      2102402
name    1053894
x       4204804
y       4204804
dtype: int64
```

```
In [17]: reduction = ts2.memory_usage(deep=True).sum() / ts.memory_usage(deep=True).sum()
```

```
In [18]: print(f"reduction:{0.2f}")
```

```
0.20
```

In all, we've reduced the in-memory footprint of this dataset to 1/5 of its original size.

See [Categorical data](#) for more on Categorical and [dtypes](#) for an overview of all of pandas' dtypes.

2.24.3 Use chunking

Some workloads can be achieved with chunking: splitting a large problem like “convert this directory of CSVs to parquet” into a bunch of small problems (“convert this individual CSV file into a Parquet file. Now repeat that for each file in this directory.”). As long as each chunk fits in memory, you can work with datasets that are much larger than memory.

Note: Chunking works well when the operation you're performing requires zero or minimal coordination between chunks. For more complicated workflows, you're better off [using another library](#).

Suppose we have an even larger “logical dataset” on disk that’s a directory of parquet files. Each file in the directory represents a different year of the entire dataset.

```
data
└── timeseries
    ├── ts-00.parquet
    ├── ts-01.parquet
    ├── ts-02.parquet
    ├── ts-03.parquet
    ├── ts-04.parquet
    ├── ts-05.parquet
    ├── ts-06.parquet
    ├── ts-07.parquet
    ├── ts-08.parquet
    ├── ts-09.parquet
    ├── ts-10.parquet
    └── ts-11.parquet
```

Now we’ll implement an out-of-core `value_counts`. The peak memory usage of this workflow is the single largest chunk, plus a small series storing the unique value counts up to this point. As long as each individual file fits in memory, this will work for arbitrary-sized datasets.

```
In [19]: %time
....: files = pathlib.Path("data/timeseries/").glob("ts*.parquet")
....: counts = pd.Series(dtype=int)
....: for path in files:
....:     df = pd.read_parquet(path)
....:     counts = counts.add(df["name"].value_counts(), fill_value=0)
....: counts.astype(int)
....:
CPU times: user 622 ms, sys: 110 ms, total: 733 ms
Wall time: 684 ms
Out[19]:
Alice      229802
Bob        229211
Charlie    229303
Dan         230621
Edith      230349
...
Victor     230502
Wendy      230038
Xavier     229553
Yvonne     228766
Zelda      229909
Length: 26, dtype: int64
```

Some readers, like `pandas.read_csv()`, offer parameters to control the `chunksize` when reading a single file.

Manually chunking is an OK option for workflows that don’t require too sophisticated of operations. Some operations, like `groupby`, are much harder to do chunkwise. In these cases, you may be better switching to a different library that implements these out-of-core algorithms for you.

2.24.4 Use other libraries

pandas is just one library offering a DataFrame API. Because of its popularity, pandas' API has become something of a standard that other libraries implement. The pandas documentation maintains a list of libraries implementing a DataFrame API in our ecosystem page.

For example, [Dask](#), a parallel computing library, has `dask.dataframe`, a pandas-like API for working with larger than memory datasets in parallel. Dask can use multiple threads or processes on a single machine, or a cluster of machines to process data in parallel.

We'll import `dask.dataframe` and notice that the API feels similar to pandas. We can use Dask's `read_parquet` function, but provide a globstring of files to read in.

```
In [20]: import dask.dataframe as dd

In [21]: ddf = dd.read_parquet("data/timeseries/ts*.parquet", engine="pyarrow")

In [22]: ddf
Out[22]:
Dask DataFrame Structure:
      id      name        x        y
npartitions=12
      int64  object  float64  float64
      ...      ...      ...      ...
...
      ...      ...      ...      ...
      ...      ...      ...      ...
      ...      ...      ...      ...
Dask Name: read-parquet, 12 tasks
```

Inspecting the `ddf` object, we see a few things

- There are familiar attributes like `.columns` and `.dtypes`
- There are familiar methods like `.groupby`, `.sum`, etc.
- There are new attributes like `npartitions` and `.divisions`

The partitions and divisions are how Dask parallelizes computation. A **Dask DataFrame** is made up of many pandas DataFrames. A single method call on a Dask DataFrame ends up making many pandas method calls, and Dask knows how to coordinate everything to get the result.

```
In [23]: ddf.columns
Out[23]: Index(['id', 'name', 'x', 'y'], dtype='object')

In [24]: ddf.dtypes
Out[24]:
id      int64
name    object
x       float64
y       float64
dtype: object

In [25]: ddf.npartitions
Out[25]: 12
```

One major difference: the `dask.dataframe` API is *lazy*. If you look at the repr above, you'll notice that the values aren't actually printed out; just the column names and dtypes. That's because Dask hasn't actually read the data yet.

Rather than executing immediately, doing operations build up a **task graph**.

```
In [26]: ddf
Out[26]:
Dask DataFrame Structure:
      id      name        x        y
npartitions=12
      int64  object  float64  float64
      ...     ...      ...      ...
...
      ...     ...      ...      ...
      ...     ...      ...      ...
      ...     ...      ...      ...
Dask Name: read-parquet, 12 tasks

In [27]: ddf["name"]
Out[27]:
Dask Series Structure:
npartitions=12
object
...
...
...
...
Name: name, dtype: object
Dask Name: getitem, 24 tasks

In [28]: ddf["name"].value_counts()
Out[28]:
Dask Series Structure:
npartitions=1
int64
...
Name: name, dtype: int64
Dask Name: value-counts-agg, 39 tasks
```

Each of these calls is instant because the result isn't being computed yet. We're just building up a list of computation to do when someone needs the result. Dask knows that the return type of a `pandas.Series.value_counts` is a pandas Series with a certain dtype and a certain name. So the Dask version returns a Dask Series with the same dtype and the same name.

To get the actual result you can call `.compute()`.

```
In [29]: %time ddf["name"].value_counts().compute()
CPU times: user 885 ms, sys: 77.5 ms, total: 962 ms
Wall time: 526 ms
Out[29]:
Laura      230906
Ingrid     230838
Kevin       230698
Dan         230621
Frank       230595
...
Ray          229603
Xavier      229553
```

(continues on next page)

(continued from previous page)

```
Charlie    229303
Bob        229211
Yvonne     228766
Name: name, Length: 26, dtype: int64
```

At that point, you get back the same thing you'd get with pandas, in this case a concrete pandas Series with the count of each name.

Calling `.compute` causes the full task graph to be executed. This includes reading the data, selecting the columns, and doing the `value_counts`. The execution is done *in parallel* where possible, and Dask tries to keep the overall memory footprint small. You can work with datasets that are much larger than memory, as long as each partition (a regular pandas DataFrame) fits in memory.

By default, `dask.dataframe` operations use a threadpool to do operations in parallel. We can also connect to a cluster to distribute the work on many machines. In this case we'll connect to a local "cluster" made up of several processes on this single machine.

```
>>> from dask.distributed import Client, LocalCluster

>>> cluster = LocalCluster()
>>> client = Client(cluster)
>>> client
<Client: 'tcp://127.0.0.1:53349' processes=4 threads=8, memory=17.18 GB>
```

Once this `client` is created, all of Dask's computation will take place on the cluster (which is just processes in this case).

Dask implements the most used parts of the pandas API. For example, we can do a familiar groupby aggregation.

```
In [30]: %time ddf.groupby("name")[['x', "y"]].mean().compute().head()
CPU times: user 1.88 s, sys: 302 ms, total: 2.18 s
Wall time: 899 ms
Out[30]:
          x         y
name
Alice   0.000086 -0.001170
Bob    -0.000843 -0.000799
Charlie 0.000564 -0.000038
Dan     0.000584  0.000818
Edith  -0.000116 -0.000044
```

The grouping and aggregation is done out-of-core and in parallel.

When Dask knows the divisions of a dataset, certain optimizations are possible. When reading parquet datasets written by dask, the divisions will be known automatically. In this case, since we created the parquet files manually, we need to supply the divisions manually.

```
In [31]: N = 12

In [32]: starts = [f"20{i:>02d}-01-01" for i in range(N)]

In [33]: ends = [f"20{i:>02d}-12-13" for i in range(N)]

In [34]: divisions = tuple(pd.to_datetime(starts)) + (pd.Timestamp(ends[-1]),)
```

(continues on next page)

(continued from previous page)

In [35]: ddf.divisions = divisions**In [36]:** ddf**Out[36]:**

Dask DataFrame Structure:

	id	name	x	y
npartitions=12				
2000-01-01	int64	object	float64	float64
2001-01-01
...
2011-01-01
2011-12-13

Dask Name: read-parquet, 12 tasks

Now we can do things like fast random access with .loc.

In [37]: ddf.loc["2002-01-01 12:01":"2002-01-01 12:05"].compute()**Out[37]:**

	id	name	x	y
timestamp				
2002-01-01 12:01:00	983	Laura	0.243985	-0.079392
2002-01-01 12:02:00	1001	Laura	-0.523119	-0.226026
2002-01-01 12:03:00	1059	Oliver	0.612886	0.405680
2002-01-01 12:04:00	993	Kevin	0.451977	0.332947
2002-01-01 12:05:00	1014	Yvonne	-0.948681	0.361748

Dask knows to just look in the 3rd partition for selecting values in 2002. It doesn't need to look at any other data.

Many workflows involve a large amount of data and processing it in a way that reduces the size to something that fits in memory. In this case, we'll resample to daily frequency and take the mean. Once we've taken the mean, we know the results will fit in memory, so we can safely call compute without running out of memory. At that point it's just a regular pandas object.

In [38]: ddf[["x", "y"]].resample("1D").mean().cumsum().compute().plot()**Out[38]:** <AxesSubplot:xlabel='timestamp'>

These Dask examples have all been done using multiple processes on a single machine. Dask can be deployed on a cluster to scale up to even larger datasets.

You see more dask examples at <https://examples.dask.org>.

2.25 Sparse data structures

pandas provides data structures for efficiently storing sparse data. These are not necessarily sparse in the typical “mostly 0”. Rather, you can view these objects as being “compressed” where any data matching a specific value (NaN / missing value, though any value can be chosen, including 0) is omitted. The compressed values are not actually stored in the array.

```
In [1]: arr = np.random.randn(10)
In [2]: arr[2:-2] = np.nan
In [3]: ts = pd.Series(pd.arrays.SparseArray(arr))
In [4]: ts
Out[4]:
0    0.469112
1   -0.282863
```

(continues on next page)

(continued from previous page)

```

2      NaN
3      NaN
4      NaN
5      NaN
6      NaN
7      NaN
8   -0.861849
9   -2.104569
dtype: Sparse[float64, nan]

```

Notice the dtype, `Sparse[float64, nan]`. The `nan` means that elements in the array that are `nan` aren't actually stored, only the non-`nan` elements are. Those non-`nan` elements have a `float64` dtype.

The sparse objects exist for memory efficiency reasons. Suppose you had a large, mostly NA DataFrame:

```

In [5]: df = pd.DataFrame(np.random.randn(10000, 4))

In [6]: df.iloc[:9998] = np.nan

In [7]: sdf = df.astype(pd.SparseDtype("float", np.nan))

In [8]: sdf.head()
Out[8]:
   0   1   2   3
0  NaN  NaN  NaN  NaN
1  NaN  NaN  NaN  NaN
2  NaN  NaN  NaN  NaN
3  NaN  NaN  NaN  NaN
4  NaN  NaN  NaN  NaN

In [9]: sdf.dtypes
Out[9]:
0    Sparse[float64, nan]
1    Sparse[float64, nan]
2    Sparse[float64, nan]
3    Sparse[float64, nan]
dtype: object

In [10]: sdf.sparse.density
Out[10]: 0.0002

```

As you can see, the density (% of values that have not been “compressed”) is extremely low. This sparse object takes up much less memory on disk (pickled) and in the Python interpreter.

```

In [11]: 'dense : {:.0f} bytes'.format(df.memory_usage().sum() / 1e3)
Out[11]: 'dense : 320.13 bytes'

In [12]: 'sparse: {:.0f} bytes'.format(sdf.memory_usage().sum() / 1e3)
Out[12]: 'sparse: 0.22 bytes'

```

Functionally, their behavior should be nearly identical to their dense counterparts.

2.25.1 SparseArray

`arrays.SparseArray` is a `ExtensionArray` for storing an array of sparse values (see `dtypes` for more on extension arrays). It is a 1-dimensional ndarray-like object storing only values distinct from the `fill_value`:

```
In [13]: arr = np.random.randn(10)
In [14]: arr[2:5] = np.nan
In [15]: arr[7:8] = np.nan
In [16]: sparr = pd.arrays.SparseArray(arr)
In [17]: sparr
Out[17]:
[-1.9556635297215477, -1.6588664275960427, nan, nan, nan, 1.1589328886422277, 0.
˓→14529711373305043, nan, 0.6060271905134522, 1.3342113401317768]
Fill: nan
IntIndex
Indices: array([0, 1, 5, 6, 8, 9], dtype=int32)
```

A sparse array can be converted to a regular (dense) ndarray with `numpy.asarray()`

```
In [18]: np.asarray(sparr)
Out[18]:
array([-1.9557, -1.6589,      nan,      nan,      nan,  1.1589,  0.1453,
       nan,  0.606 ,  1.3342])
```

2.25.2 SparseDtype

The `SparseArray.dtype` property stores two pieces of information

1. The dtype of the non-sparse values
2. The scalar fill value

```
In [19]: sparr.dtype
Out[19]: Sparse[float64, nan]
```

A `SparseDtype` may be constructed by passing only a dtype

```
In [20]: pd.SparseDtype(np.dtype('datetime64[ns]'))
Out[20]: Sparse[datetime64[ns], numpy.datetime64('NaT')]
```

in which case a default fill value will be used (for NumPy dtypes this is often the “missing” value for that dtype). To override this default an explicit fill value may be passed instead

```
In [21]: pd.SparseDtype(np.dtype('datetime64[ns]'),
.....           fill_value=pd.Timestamp('2017-01-01'))
.....
```

Out[21]: Sparse[datetime64[ns], Timestamp('2017-01-01 00:00:00')]

Finally, the string alias '`Sparse[dtype]`' may be used to specify a sparse dtype in many places

```
In [22]: pd.array([1, 0, 0, 2], dtype='Sparse[int]')
Out[22]:
[1, 0, 0, 2]
Fill: 0
IntIndex
Indices: array([0, 3], dtype=int32)
```

2.25.3 Sparse accessor

pandas provides a `.sparse` accessor, similar to `.str` for string data, `.cat` for categorical data, and `.dt` for datetime-like data. This namespace provides attributes and methods that are specific to sparse data.

```
In [23]: s = pd.Series([0, 0, 1, 2], dtype="Sparse[int]")
In [24]: s.sparse.density
Out[24]: 0.5
In [25]: s.sparse.fill_value
Out[25]: 0
```

This accessor is available only on data with `SparseDtype`, and on the `Series` class itself for creating a Series with sparse data from a scipy COO matrix with.

New in version 0.25.0.

A `.sparse` accessor has been added for `DataFrame` as well. See [Sparse accessor](#) for more.

2.25.4 Sparse calculation

You can apply NumPy `ufuncs` to `SparseArray` and get a `SparseArray` as a result.

```
In [26]: arr = pd.arrays.SparseArray([1., np.nan, np.nan, -2., np.nan])
In [27]: np.abs(arr)
Out[27]:
[1.0, nan, nan, 2.0, nan]
Fill: nan
IntIndex
Indices: array([0, 3], dtype=int32)
```

The `ufunc` is also applied to `fill_value`. This is needed to get the correct dense result.

```
In [28]: arr = pd.arrays.SparseArray([1., -1, -1, -2., -1], fill_value=-1)
In [29]: np.abs(arr)
Out[29]:
[1, 1, 1, 2.0, 1]
Fill: 1
IntIndex
Indices: array([3], dtype=int32)
```

(continues on next page)

(continued from previous page)

```
In [30]: np.abs(arr).to_dense()
Out[30]: array([1., 1., 1., 2., 1.])
```

2.25.5 Migrating

Note: `SparseSeries` and `SparseDataFrame` were removed in pandas 1.0.0. This migration guide is present to aid in migrating from previous versions.

In older versions of pandas, the `SparseSeries` and `SparseDataFrame` classes (documented below) were the preferred way to work with sparse data. With the advent of extension arrays, these subclasses are no longer needed. Their purpose is better served by using a regular `Series` or `DataFrame` with sparse values instead.

Note: There's no performance or memory penalty to using a `Series` or `DataFrame` with sparse values, rather than a `SparseSeries` or `SparseDataFrame`.

This section provides some guidance on migrating your code to the new style. As a reminder, you can use the Python warnings module to control warnings. But we recommend modifying your code, rather than ignoring the warning.

Construction

From an array-like, use the regular `Series` or `DataFrame` constructors with `SparseArray` values.

```
# Previous way
>>> pd.SparseDataFrame({"A": [0, 1]})
```

```
# New way
In [31]: pd.DataFrame({"A": pd.arrays.SparseArray([0, 1])})
Out[31]:
   A
0  0
1  1
```

From a SciPy sparse matrix, use `DataFrame.sparse.from_spmatrix()`,

```
# Previous way
>>> from scipy import sparse
>>> mat = sparse.eye(3)
>>> df = pd.SparseDataFrame(mat, columns=['A', 'B', 'C'])
```

```
# New way
In [32]: from scipy import sparse

In [33]: mat = sparse.eye(3)

In [34]: df = pd.DataFrame.sparse.from_spmatrix(mat, columns=['A', 'B', 'C'])

In [35]: df.dtypes
Out[35]:
A    Sparse[float64, 0]
```

(continues on next page)

(continued from previous page)

```
B    Sparse[float64, 0]
C    Sparse[float64, 0]
dtype: object
```

Conversion

From sparse to dense, use the `.sparse` accessors

```
In [36]: df.sparse.to_dense()
Out[36]:
   A    B    C
0  1.0  0.0  0.0
1  0.0  1.0  0.0
2  0.0  0.0  1.0

In [37]: df.sparse.to_coo()
Out[37]:
<3x3 sparse matrix of type '<class 'numpy.float64'>'
      with 3 stored elements in COOrdinate format>
```

From dense to sparse, use `DataFrame.astype()` with a `SparseDtype`.

```
In [38]: dense = pd.DataFrame({"A": [1, 0, 0, 1]})

In [39]: dtype = pd.SparseDtype(int, fill_value=0)

In [40]: dense.astype(dtype)
Out[40]:
   A
0  1
1  0
2  0
3  1
```

Sparse Properties

Sparse-specific properties, like `density`, are available on the `.sparse` accessor.

```
In [41]: df.sparse.density
Out[41]: 0.3333333333333333
```

General differences

In a `SparseDataFrame`, *all* columns were sparse. A `DataFrame` can have a mixture of sparse and dense columns. As a consequence, assigning new columns to a `DataFrame` with sparse values will not automatically convert the input to be sparse.

```
# Previous Way
>>> df = pd.SparseDataFrame({"A": [0, 1]})
>>> df['B'] = [0, 0] # implicitly becomes Sparse
>>> df['B'].dtype
Sparse[int64, nan]
```

Instead, you'll need to ensure that the values being assigned are sparse

```
In [42]: df = pd.DataFrame({"A": pd.arrays.SparseArray([0, 1])})  
  
In [43]: df['B'] = [0, 0] # remains dense  
  
In [44]: df['B'].dtype  
Out[44]: dtype('int64')  
  
In [45]: df['B'] = pd.arrays.SparseArray([0, 0])  
  
In [46]: df['B'].dtype  
Out[46]: Sparse[int64, 0]
```

The `SparseDataFrame.default_kind` and `SparseDataFrame.default_fill_value` attributes have no replacement.

2.25.6 Interaction with `scipy.sparse`

Use `DataFrame.sparse.from_spmatrix()` to create a DataFrame with sparse values from a sparse matrix.

New in version 0.25.0.

```
In [47]: from scipy.sparse import csr_matrix  
  
In [48]: arr = np.random.random(size=(1000, 5))  
  
In [49]: arr[arr < .9] = 0  
  
In [50]: sp_arr = csr_matrix(arr)  
  
In [51]: sp_arr  
Out[51]:  
<1000x5 sparse matrix of type '<class 'numpy.float64'>'  
      with 517 stored elements in Compressed Sparse Row format>  
  
In [52]: sdf = pd.DataFrame.sparse.from_spmatrix(sp_arr)  
  
In [53]: sdf.head()  
Out[53]:  
          0    1    2    3    4  
0  0.956380  0.0  0.0  0.000000  0.0  
1  0.000000  0.0  0.0  0.000000  0.0  
2  0.000000  0.0  0.0  0.000000  0.0  
3  0.000000  0.0  0.0  0.000000  0.0  
4  0.999552  0.0  0.0  0.956153  0.0  
  
In [54]: sdf.dtypes  
Out[54]:  
0    Sparse[float64, 0]  
1    Sparse[float64, 0]  
2    Sparse[float64, 0]  
3    Sparse[float64, 0]  
4    Sparse[float64, 0]  
dtype: object
```

All sparse formats are supported, but matrices that are not in COOndinate format will be converted, copying data as needed. To convert back to sparse SciPy matrix in COO format, you can use the `DataFrame.sparse.to_coo()` method:

```
In [55]: sdf.sparse.to_coo()
Out[55]:
<1000x5 sparse matrix of type '<class 'numpy.float64'>'
      with 517 stored elements in COOndinate format>
```

`Series.sparse.to_coo()` is implemented for transforming a `Series` with sparse values indexed by a `MultiIndex` to a `scipy.sparse.coo_matrix`.

The method requires a `MultiIndex` with two or more levels.

```
In [56]: s = pd.Series([3.0, np.nan, 1.0, 3.0, np.nan, np.nan])
```

```
In [57]: s.index = pd.MultiIndex.from_tuples(
    ....:     [
    ....:         (1, 2, "a", 0),
    ....:         (1, 2, "a", 1),
    ....:         (1, 1, "b", 0),
    ....:         (1, 1, "b", 1),
    ....:         (2, 1, "b", 0),
    ....:         (2, 1, "b", 1),
    ....:     ],
    ....:     names=["A", "B", "C", "D"],
    ....: )
    ....:
```

```
In [58]: ss = s.astype('Sparse')
```

```
In [59]: ss
Out[59]:
A   B   C   D
1   2   a   0   3.0
                  1   NaN
        b   0   1.0
                  1   3.0
2   1   b   0   NaN
                  1   NaN
dtype: Sparse[float64, nan]
```

In the example below, we transform the `Series` to a sparse representation of a 2-d array by specifying that the first and second `MultiIndex` levels define labels for the rows and the third and fourth levels define labels for the columns. We also specify that the column and row labels should be sorted in the final sparse representation.

```
In [60]: A, rows, columns = ss.sparse.to_coo(
    ....:     row_levels=["A", "B"], column_levels=["C", "D"], sort_labels=True
    ....: )
    ....:
```

```
In [61]: A
Out[61]:
<3x4 sparse matrix of type '<class 'numpy.float64'>'
```

(continues on next page)

(continued from previous page)

```
with 3 stored elements in COOrdinate format>

In [62]: A.todense()
Out[62]:
matrix([[0., 0., 1., 3.],
       [3., 0., 0., 0.],
       [0., 0., 0., 0.]])
```

In [63]: rows
Out[63]: [(1, 1), (1, 2), (2, 1)]

In [64]: columns
Out[64]: [('a', 0), ('a', 1), ('b', 0), ('b', 1)]

Specifying different row and column labels (and not sorting them) yields a different sparse matrix:

```
In [65]: A, rows, columns = ss.sparse.to_coo(
.....    row_levels=["A", "B", "C"], column_levels=["D"], sort_labels=False
.....)
.....
```

In [66]: A
Out[66]:
<3x2 sparse matrix of type '<class 'numpy.float64'>'
with 3 stored elements in COOrdinate format>

In [67]: A.todense()
Out[67]:
matrix([[3., 0.],
 [1., 3.],
 [0., 0.]])

In [68]: rows
Out[68]: [(1, 2, 'a'), (1, 1, 'b'), (2, 1, 'b')]

In [69]: columns
Out[69]: [(0,), (1,)]

A convenience method `Series.sparse.from_coo()` is implemented for creating a `Series` with sparse values from a `scipy.sparse.coo_matrix`.

```
In [70]: from scipy import sparse
```

In [71]: A = sparse.coo_matrix(([3.0, 1.0, 2.0], ([1, 0, 0], [0, 2, 3])), shape=(3, 4))

In [72]: A
Out[72]:
<3x4 sparse matrix of type '<class 'numpy.float64'>'
with 3 stored elements in COOrdinate format>

In [73]: A.todense()
Out[73]:

(continues on next page)

(continued from previous page)

```
matrix([[0., 0., 1., 2.],
       [3., 0., 0., 0.],
       [0., 0., 0., 0.]])
```

The default behaviour (with `dense_index=False`) simply returns a `Series` containing only the non-null entries.

```
In [74]: ss = pd.Series.sparse.from_coo(A)
```

```
In [75]: ss
```

```
Out[75]:
```

0	2	1.0
	3	2.0
1	0	3.0

```
dtype: Sparse[float64, nan]
```

Specifying `dense_index=True` will result in an index that is the Cartesian product of the row and columns coordinates of the matrix. Note that this will consume a significant amount of memory (relative to `dense_index=False`) if the sparse matrix is large (and sparse) enough.

```
In [76]: ss_dense = pd.Series.sparse.from_coo(A, dense_index=True)
```

```
In [77]: ss_dense
```

```
Out[77]:
```

0	0	NaN
	1	NaN
	2	1.0
	3	2.0
1	0	3.0
	1	NaN
	2	NaN
	3	NaN
2	0	NaN
	1	NaN
	2	NaN
	3	NaN

```
dtype: Sparse[float64, nan]
```

2.26 Frequently Asked Questions (FAQ)

2.26.1 DataFrame memory usage

The memory usage of a `DataFrame` (including the index) is shown when calling the `info()`. A configuration option, `display.memory_usage` (see [the list of options](#)), specifies if the `DataFrame`'s memory usage will be displayed when invoking the `df.info()` method.

For example, the memory usage of the `DataFrame` below is shown when calling `info()`:

```
In [1]: dtypes = [
...:     "int64",
...:     "float64",
...:     "datetime64[ns]",
```

(continues on next page)

(continued from previous page)

```

...:     "timedelta64[ns]",
...:     "complex128",
...:     "object",
...:     "bool",
...:   ]
...:
In [2]: n = 5000

In [3]: data = {t: np.random.randint(100, size=n).astype(t) for t in dtypes}

In [4]: df = pd.DataFrame(data)

In [5]: df["categorical"] = df["object"].astype("category")

In [6]: df.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 5000 entries, 0 to 4999
Data columns (total 8 columns):
 #   Column           Non-Null Count  Dtype  
--- 
 0   int64            5000 non-null    int64  
 1   float64          5000 non-null    float64 
 2   datetime64[ns]   5000 non-null    datetime64[ns]
 3   timedelta64[ns]  5000 non-null    timedelta64[ns]
 4   complex128       5000 non-null    complex128
 5   object            5000 non-null    object  
 6   bool              5000 non-null    bool    
 7   categorical       5000 non-null    category
dtypes: bool(1), category(1), complex128(1), datetime64[ns](1), float64(1), int64(1), object(1), timedelta64[ns](1)
memory usage: 288.2+ KB

```

The + symbol indicates that the true memory usage could be higher, because pandas does not count the memory used by values in columns with `dtype=object`.

Passing `memory_usage='deep'` will enable a more accurate memory usage report, accounting for the full usage of the contained objects. This is optional as it can be expensive to do this deeper introspection.

```

In [7]: df.info(memory_usage="deep")
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 5000 entries, 0 to 4999
Data columns (total 8 columns):
 #   Column           Non-Null Count  Dtype  
--- 
 0   int64            5000 non-null    int64  
 1   float64          5000 non-null    float64 
 2   datetime64[ns]   5000 non-null    datetime64[ns]
 3   timedelta64[ns]  5000 non-null    timedelta64[ns]
 4   complex128       5000 non-null    complex128
 5   object            5000 non-null    object  
 6   bool              5000 non-null    bool    
 7   categorical       5000 non-null    category

```

(continues on next page)

(continued from previous page)

```
dtypes: bool(1), category(1), complex128(1), datetime64[ns](1), float64(1), int64(1),  
        object(1), timedelta64[ns](1)  
memory usage: 424.7 KB
```

By default the display option is set to True but can be explicitly overridden by passing the `memory_usage` argument when invoking `df.info()`.

The memory usage of each column can be found by calling the `memory_usage()` method. This returns a Series with an index represented by column names and memory usage of each column shown in bytes. For the DataFrame above, the memory usage of each column and the total memory usage can be found with the `memory_usage` method:

```
In [8]: df.memory_usage()  
Out[8]:  
Index          128  
int64        40000  
float64      40000  
datetime64[ns] 40000  
timedelta64[ns] 40000  
complex128    80000  
object        40000  
bool           5000  
categorical   9968  
dtype: int64  
  
# total memory usage of dataframe  
In [9]: df.memory_usage().sum()  
Out[9]: 295096
```

By default the memory usage of the DataFrame's index is shown in the returned Series, the memory usage of the index can be suppressed by passing the `index=False` argument:

```
In [10]: df.memory_usage(index=False)  
Out[10]:  
int64        40000  
float64      40000  
datetime64[ns] 40000  
timedelta64[ns] 40000  
complex128    80000  
object        40000  
bool           5000  
categorical   9968  
dtype: int64
```

The memory usage displayed by the `info()` method utilizes the `memory_usage()` method to determine the memory usage of a DataFrame while also formatting the output in human-readable units (base-2 representation; i.e. 1KB = 1024 bytes).

See also [Categorical Memory Usage](#).

2.26.2 Using if/truth statements with pandas

pandas follows the NumPy convention of raising an error when you try to convert something to a `bool`. This happens in an `if`-statement or when using the boolean operations: `and`, `or`, and `not`. It is not clear what the result of the following code should be:

```
>>> if pd.Series([False, True, False]):  
...     pass
```

Should it be `True` because it's not zero-length, or `False` because there are `False` values? It is unclear, so instead, pandas raises a `ValueError`:

```
>>> if pd.Series([False, True, False]):  
...     print("I was true")  
Traceback  
...  
ValueError: The truth value of an array is ambiguous. Use a.empty, a.any() or a.all().
```

You need to explicitly choose what you want to do with the `DataFrame`, e.g. use `any()`, `all()` or `empty()`. Alternatively, you might want to compare if the pandas object is `None`:

```
>>> if pd.Series([False, True, False]) is not None:  
...     print("I was not None")  
I was not None
```

Below is how to check if any of the values are `True`:

```
>>> if pd.Series([False, True, False]).any():  
...     print("I am any")  
I am any
```

To evaluate single-element pandas objects in a boolean context, use the method `bool()`:

```
In [11]: pd.Series([True]).bool()  
Out[11]: True  
  
In [12]: pd.Series([False]).bool()  
Out[12]: False  
  
In [13]: pd.DataFrame([[True]]).bool()  
Out[13]: True  
  
In [14]: pd.DataFrame([[False]]).bool()  
Out[14]: False
```

Bitwise boolean

Bitwise boolean operators like `==` and `!=` return a boolean `Series`, which is almost always what you want anyways.

```
>>> s = pd.Series(range(5))
>>> s == 4
0    False
1    False
2    False
3    False
4    True
dtype: bool
```

See [boolean comparisons](#) for more examples.

Using the `in` operator

Using the Python `in` operator on a `Series` tests for membership in the index, not membership among the values.

```
In [15]: s = pd.Series(range(5), index=list("abcde"))
In [16]: 2 in s
Out[16]: False
In [17]: 'b' in s
Out[17]: True
```

If this behavior is surprising, keep in mind that using `in` on a Python dictionary tests keys, not values, and `Series` are dict-like. To test for membership in the values, use the method `isin()`:

```
In [18]: s.isin([2])
Out[18]:
a    False
b    False
c    True
d    False
e    False
dtype: bool
In [19]: s.isin([2]).any()
Out[19]: True
```

For `DataFrames`, likewise, `in` applies to the column axis, testing for membership in the list of column names.

2.26.3 Mutating with User Defined Function (UDF) methods

This section applies to pandas methods that take a UDF. In particular, the methods `.apply`, `.aggregate`, `.transform`, and `.filter`.

It is a general rule in programming that one should not mutate a container while it is being iterated over. Mutation will invalidate the iterator, causing unexpected behavior. Consider the example:

```
In [20]: values = [0, 1, 2, 3, 4, 5]
In [21]: n_removed = 0
In [22]: for k, value in enumerate(values):
....:     idx = k - n_removed
....:     if value % 2 == 1:
....:         del values[idx]
....:     n_removed += 1
....: else:
....:     values[idx] = value + 1
....:
In [23]: values
Out[23]: [1, 4, 5]
```

One probably would have expected that the result would be [1, 3, 5]. When using a pandas method that takes a UDF, internally pandas is often iterating over the DataFrame or other pandas object. Therefore, if the UDF mutates (changes) the DataFrame, unexpected behavior can arise.

Here is a similar example with `DataFrame.apply()`:

```
In [24]: def f(s):
....:     s.pop("a")
....:     return s
....:
In [25]: df = pd.DataFrame({"a": [1, 2, 3], "b": [4, 5, 6]})
In [26]: try:
....:     df.apply(f, axis="columns")
....: except Exception as err:
....:     print(repr(err))
....:
KeyError('a')
```

To resolve this issue, one can make a copy so that the mutation does not apply to the container being iterated over.

```
In [27]: values = [0, 1, 2, 3, 4, 5]
In [28]: n_removed = 0
In [29]: for k, value in enumerate(values.copy()):
....:     idx = k - n_removed
....:     if value % 2 == 1:
....:         del values[idx]
....:     n_removed += 1
```

(continues on next page)

(continued from previous page)

```
....:  
      else:  
      ....:     values[idx] = value + 1  
      ....:
```

In [30]: values
Out[30]: [1, 3, 5]

```
In [31]: def f(s):  
....:     s = s.copy()  
....:     s.pop("a")  
....:     return s  
....:
```

In [32]: df = pd.DataFrame({"a": [1, 2, 3], 'b': [4, 5, 6]})

In [33]: df.apply(f, axis="columns")
Out[33]:

	b
0	4
1	5
2	6

2.26.4 NaN, Integer NA values and NA type promotions

Choice of NA representation

For lack of NA (missing) support from the ground up in NumPy and Python in general, we were given the difficult choice between either:

- A *masked array* solution: an array of data and an array of boolean values indicating whether a value is there or is missing.
- Using a special sentinel value, bit pattern, or set of sentinel values to denote NA across the dtypes.

For many reasons we chose the latter. After years of production use it has proven, at least in my opinion, to be the best decision given the state of affairs in NumPy and Python in general. The special value `NaN` (Not-A-Number) is used everywhere as the NA value, and there are API functions `isna` and `notna` which can be used across the dtypes to detect NA values.

However, it comes with it a couple of trade-offs which I most certainly have not ignored.

Support for integer NA

In the absence of high performance NA support being built into NumPy from the ground up, the primary casualty is the ability to represent NAs in integer arrays. For example:

```
In [34]: s = pd.Series([1, 2, 3, 4, 5], index=list("abcde"))  
  
In [35]: s  
Out[35]:
```

	a
0	1
1	2

(continues on next page)

(continued from previous page)

```
c    3
d    4
e    5
dtype: int64

In [36]: s.dtype
Out[36]: dtype('int64')

In [37]: s2 = s.reindex(["a", "b", "c", "f", "u"])

In [38]: s2
Out[38]:
a    1.0
b    2.0
c    3.0
f    NaN
u    NaN
dtype: float64

In [39]: s2.dtype
Out[39]: dtype('float64')
```

This trade-off is made largely for memory and performance reasons, and also so that the resulting Series continues to be “numeric”.

If you need to represent integers with possibly missing values, use one of the nullable-integer extension dtypes provided by pandas

- [Int8Dtype](#)
- [Int16Dtype](#)
- [Int32Dtype](#)
- [Int64Dtype](#)

```
In [40]: s_int = pd.Series([1, 2, 3, 4, 5], index=list("abcde"), dtype=pd.Int64Dtype())

In [41]: s_int
Out[41]:
a    1
b    2
c    3
d    4
e    5
dtype: Int64

In [42]: s_int.dtype
Out[42]: Int64Dtype()

In [43]: s2_int = s_int.reindex(["a", "b", "c", "f", "u"])

In [44]: s2_int
Out[44]:
a    1
```

(continues on next page)

(continued from previous page)

```
b      2
c      3
f    <NA>
u    <NA>
dtype: Int64
```

In [45]: s2_int.dtype

Out[45]: Int64Dtype()

See *Nullable integer data type* for more.

NA type promotions

When introducing NAs into an existing Series or DataFrame via `reindex()` or some other means, boolean and integer types will be promoted to a different dtype in order to store the NAs. The promotions are summarized in this table:

Typeclass	Promotion dtype for storing NAs
<code>floating</code>	no change
<code>object</code>	no change
<code>integer</code>	cast to <code>float64</code>
<code>boolean</code>	cast to <code>object</code>

While this may seem like a heavy trade-off, I have found very few cases where this is an issue in practice i.e. storing values greater than $2^{**}53$. Some explanation for the motivation is in the next section.

Why not make NumPy like R?

Many people have suggested that NumPy should simply emulate the NA support present in the more domain-specific statistical programming language R. Part of the reason is the NumPy type hierarchy:

Typeclass	Dtypes
<code>numpy.floating</code>	<code>float16, float32, float64, float128</code>
<code>numpy.integer</code>	<code>int8, int16, int32, int64</code>
<code>numpy.unsignedinteger</code>	<code>uint8, uint16, uint32, uint64</code>
<code>numpy.object_</code>	<code>object_</code>
<code>numpy.bool_</code>	<code>bool_</code>
<code>numpy.character</code>	<code>string_, unicode_</code>

The R language, by contrast, only has a handful of built-in data types: `integer`, `numeric` (floating-point), `character`, and `boolean`. NA types are implemented by reserving special bit patterns for each type to be used as the missing value. While doing this with the full NumPy type hierarchy would be possible, it would be a more substantial trade-off (especially for the 8- and 16-bit data types) and implementation undertaking.

An alternate approach is that of using masked arrays. A masked array is an array of data with an associated boolean `mask` denoting whether each value should be considered NA or not. I am personally not in love with this approach as I feel that overall it places a fairly heavy burden on the user and the library implementer. Additionally, it exacts a fairly high performance cost when working with numerical data compared with the simple approach of using `NaN`. Thus, I have chosen the Pythonic “practicality beats purity” approach and traded integer NA capability for a much simpler approach of using a special value in float and object arrays to denote NA, and promoting integer arrays to floating when NAs must be introduced.

2.26.5 Differences with NumPy

For Series and DataFrame objects, `var()` normalizes by $N-1$ to produce unbiased estimates of the sample variance, while NumPy's `var` normalizes by N , which measures the variance of the sample. Note that `cov()` normalizes by $N-1$ in both pandas and NumPy.

2.26.6 Thread-safety

As of pandas 0.11, pandas is not 100% thread safe. The known issues relate to the `copy()` method. If you are doing a lot of copying of DataFrame objects shared among threads, we recommend holding locks inside the threads where the data copying occurs.

See [this link](#) for more information.

2.26.7 Byte-ordering issues

Occasionally you may have to deal with data that were created on a machine with a different byte order than the one on which you are running Python. A common symptom of this issue is an error like:

Traceback

```
...
ValueError: Big-endian buffer not supported on little-endian compiler
```

To deal with this issue you should convert the underlying NumPy array to the native system byte order *before* passing it to Series or DataFrame constructors using something similar to the following:

```
In [46]: x = np.array(list(range(10)), ">i4") # big endian
```

```
In [47]: newx = x.byteswap().newbyteorder() # force native byteorder
```

```
In [48]: s = pd.Series(newx)
```

See the NumPy documentation on byte order for more details.

2.27 Cookbook

This is a repository for *short and sweet* examples and links for useful pandas recipes. We encourage users to add to this documentation.

Adding interesting links and/or inline examples to this section is a great *First Pull Request*.

Simplified, condensed, new-user friendly, in-line examples have been inserted where possible to augment the StackOverflow and GitHub links. Many of the links contain expanded information, above what the in-line examples offer.

pandas (`pd`) and NumPy (`np`) are the only two abbreviated imported modules. The rest are kept explicitly imported for newer users.

2.27.1 Idioms

These are some neat pandas idioms

if-then/if-then-else on one column, and assignment to another one or more columns:

```
In [1]: df = pd.DataFrame(
...:     {"AAA": [4, 5, 6, 7], "BBB": [10, 20, 30, 40], "CCC": [100, 50, -30, -50]}
...: )
...:

In [2]: df
Out[2]:
   AAA  BBB  CCC
0    4   10  100
1    5   20   50
2    6   30  -30
3    7   40  -50
```

if-then...

An if-then on one column

```
In [3]: df.loc[df.AAA >= 5, "BBB"] = -1

In [4]: df
Out[4]:
   AAA  BBB  CCC
0    4   10  100
1    5   -1   50
2    6   -1  -30
3    7   -1  -50
```

An if-then with assignment to 2 columns:

```
In [5]: df.loc[df.AAA >= 5, ["BBB", "CCC"]] = 555

In [6]: df
Out[6]:
   AAA  BBB  CCC
0    4   10  100
1    5   555  555
2    6   555  555
3    7   555  555
```

Add another line with different logic, to do the -else

```
In [7]: df.loc[df.AAA < 5, ["BBB", "CCC"]] = 2000

In [8]: df
Out[8]:
   AAA  BBB  CCC
0    4  2000  2000
```

(continues on next page)

(continued from previous page)

1	5	555	555
2	6	555	555
3	7	555	555

Or use pandas where after you've set up a mask

```
In [9]: df_mask = pd.DataFrame(
....:     {"AAA": [True] * 4, "BBB": [False] * 4, "CCC": [True, False] * 2}
....: )
....:

In [10]: df.where(df_mask, -1000)
Out[10]:
   AAA    BBB    CCC
0    4 -1000   2000
1    5 -1000  -1000
2    6 -1000   555
3    7 -1000 -1000
```

if-then-else using NumPy's where()

```
In [11]: df = pd.DataFrame(
....:     {"AAA": [4, 5, 6, 7], "BBB": [10, 20, 30, 40], "CCC": [100, 50, -30, -50]}
....: )
....:

In [12]: df
Out[12]:
   AAA    BBB    CCC
0    4     10    100
1    5     20     50
2    6     30    -30
3    7     40    -50

In [13]: df["logic"] = np.where(df["AAA"] > 5, "high", "low")

In [14]: df
Out[14]:
   AAA    BBB    CCC  logic
0    4     10    100    low
1    5     20     50    low
2    6     30    -30   high
3    7     40    -50   high
```

Splitting

Split a frame with a boolean criterion

```
In [15]: df = pd.DataFrame(
....:     {"AAA": [4, 5, 6, 7], "BBB": [10, 20, 30, 40], "CCC": [100, 50, -30, -50]}
....:
....:

In [16]: df
Out[16]:
   AAA  BBB  CCC
0    4   10  100
1    5   20   50
2    6   30  -30
3    7   40  -50

In [17]: df[df.AAA <= 5]
Out[17]:
   AAA  BBB  CCC
0    4   10  100
1    5   20   50

In [18]: df[df.AAA > 5]
Out[18]:
   AAA  BBB  CCC
2    6   30  -30
3    7   40  -50
```

Building criteria

Select with multi-column criteria

```
In [19]: df = pd.DataFrame(
....:     {"AAA": [4, 5, 6, 7], "BBB": [10, 20, 30, 40], "CCC": [100, 50, -30, -50]}
....:
....:

In [20]: df
Out[20]:
   AAA  BBB  CCC
0    4   10  100
1    5   20   50
2    6   30  -30
3    7   40  -50
```

...and (without assignment returns a Series)

```
In [21]: df.loc[(df["BBB"] < 25) & (df["CCC"] >= -40), "AAA"]
Out[21]:
0    4
1    5
Name: AAA, dtype: int64
```

...or (without assignment returns a Series)

```
In [22]: df.loc[(df["BBB"] > 25) | (df["CCC"] >= -40), "AAA"]
Out[22]:
0    4
1    5
2    6
3    7
Name: AAA, dtype: int64
```

...or (with assignment modifies the DataFrame.)

```
In [23]: df.loc[(df["BBB"] > 25) | (df["CCC"] >= 75), "AAA"] = 0.1
In [24]: df
Out[24]:
   AAA  BBB  CCC
0  0.1   10  100
1  5.0   20   50
2  0.1   30  -30
3  0.1   40  -50
```

Select rows with data closest to certain value using argsort

```
In [25]: df = pd.DataFrame(
.....:     {"AAA": [4, 5, 6, 7], "BBB": [10, 20, 30, 40], "CCC": [100, 50, -30, -50]}
.....:
.....:

In [26]: df
Out[26]:
   AAA  BBB  CCC
0    4   10  100
1    5   20   50
2    6   30  -30
3    7   40  -50

In [27]: aValue = 43.0

In [28]: df.loc[(df.CCC - aValue).abs().argsort()]
Out[28]:
   AAA  BBB  CCC
1    5   20   50
0    4   10  100
2    6   30  -30
3    7   40  -50
```

Dynamically reduce a list of criteria using a binary operators

```
In [29]: df = pd.DataFrame(
.....:     {"AAA": [4, 5, 6, 7], "BBB": [10, 20, 30, 40], "CCC": [100, 50, -30, -50]}
.....:
.....:
```

(continues on next page)

(continued from previous page)

```
In [30]: df
Out[30]:
   AAA  BBB  CCC
0    4    10   100
1    5    20    50
2    6    30   -30
3    7    40   -50

In [31]: Crit1 = df.AAA <= 5.5

In [32]: Crit2 = df.BBB == 10.0

In [33]: Crit3 = df.CCC > -40.0
```

One could hard code:

```
In [34]: AllCrit = Crit1 & Crit2 & Crit3
```

...Or it can be done with a list of dynamically built criteria

```
In [35]: import functools

In [36]: CritList = [Crit1, Crit2, Crit3]

In [37]: AllCrit = functools.reduce(lambda x, y: x & y, CritList)

In [38]: df[AllCrit]
Out[38]:
   AAA  BBB  CCC
0    4    10   100
```

2.27.2 Selection

Dataframes

The *indexing* docs.

Using both row labels and value conditionals

```
In [39]: df = pd.DataFrame(
....:     {"AAA": [4, 5, 6, 7], "BBB": [10, 20, 30, 40], "CCC": [100, 50, -30, -50]}
....: )
....:

In [40]: df
Out[40]:
   AAA  BBB  CCC
0    4    10   100
1    5    20    50
2    6    30   -30
3    7    40   -50
```

(continues on next page)

(continued from previous page)

In [41]: df[(df.AAA <= 6) & (df.index.isin([0, 2, 4]))]**Out[41]:**

	AAA	BBB	CCC
0	4	10	100
2	6	30	-30

Use loc for label-oriented slicing and iloc positional slicing GH2904

```
In [42]: df = pd.DataFrame(
    ....:     {"AAA": [4, 5, 6, 7], "BBB": [10, 20, 30, 40], "CCC": [100, 50, -30, -50]}, 
    ....:     index=["foo", "bar", "boo", "kar"], 
    ....: )
    ....:
```

There are 2 explicit slicing methods, with a third general case

1. Positional-oriented (Python slicing style : exclusive of end)
2. Label-oriented (Non-Python slicing style : inclusive of end)
3. General (Either slicing style : depends on if the slice contains labels or positions)

In [43]: df.loc["bar":"kar"] # Label**Out[43]:**

	AAA	BBB	CCC
bar	5	20	50
boo	6	30	-30
kar	7	40	-50

Generic

In [44]: df[0:3]**Out[44]:**

	AAA	BBB	CCC
foo	4	10	100
bar	5	20	50
boo	6	30	-30

In [45]: df["bar":"kar"]**Out[45]:**

	AAA	BBB	CCC
bar	5	20	50
boo	6	30	-30
kar	7	40	-50

Ambiguity arises when an index consists of integers with a non-zero start or non-unit increment.

In [46]: data = {"AAA": [4, 5, 6, 7], "BBB": [10, 20, 30, 40], "CCC": [100, 50, -30, -50]}**In [47]:** df2 = pd.DataFrame(data=data, index=[1, 2, 3, 4]) # Note index starts at 1.**In [48]:** df2.iloc[1:3] # Position-oriented**Out[48]:**

(continues on next page)

(continued from previous page)

```
AAA BBB CCC
2    5   20   50
3    6   30  -30
```

In [49]: df2.loc[1:3] # Label-oriented

Out[49]:

```
AAA BBB CCC
1    4   10  100
2    5   20   50
3    6   30  -30
```

Using inverse operator (~) to take the complement of a mask

In [50]: df = pd.DataFrame(
....: {"AAA": [4, 5, 6, 7], "BBB": [10, 20, 30, 40], "CCC": [100, 50, -30, -50]}
....:
....:

In [51]: df

Out[51]:

```
AAA BBB CCC
0    4   10  100
1    5   20   50
2    6   30  -30
3    7   40  -50
```

In [52]: df[~((df.AAA <= 6) & (df.index.isin([0, 2, 4])))]

Out[52]:

```
AAA BBB CCC
1    5   20   50
3    7   40  -50
```

New columns

Efficiently and dynamically creating new columns using applymap

In [53]: df = pd.DataFrame({"AAA": [1, 2, 1, 3], "BBB": [1, 1, 2, 2], "CCC": [2, 1, 3, 1]})

In [54]: df

Out[54]:

```
AAA BBB CCC
0    1    1    2
1    2    1    1
2    1    2    3
3    3    2    1
```

In [55]: source_cols = df.columns # Or some subset would work too

In [56]: new_cols = [str(x) + "_cat" for x in source_cols]

(continues on next page)

(continued from previous page)

```
In [57]: categories = {1: "Alpha", 2: "Beta", 3: "Charlie"}  
  
In [58]: df[new_cols] = df[source_cols].applymap(categories.get)  
  
In [59]: df  
Out[59]:
```

	AAA	BBB	CCC	AAA_cat	BBB_cat	CCC_cat
0	1	1	2	Alpha	Alpha	Beta
1	2	1	1	Beta	Alpha	Alpha
2	1	2	3	Alpha	Beta	Charlie
3	3	2	1	Charlie	Beta	Alpha

Keep other columns when using min() with groupby

```
In [60]: df = pd.DataFrame(  
.....:     {"AAA": [1, 1, 1, 2, 2, 2, 3, 3], "BBB": [2, 1, 3, 4, 5, 1, 2, 3]}  
.....:  
.....:  
  
In [61]: df  
Out[61]:
```

	AAA	BBB
0	1	2
1	1	1
2	1	3
3	2	4
4	2	5
5	2	1
6	3	2
7	3	3

Method 1 : idxmin() to get the index of the minimums

```
In [62]: df.loc[df.groupby("AAA")["BBB"].idxmin()]  
Out[62]:
```

	AAA	BBB
1	1	1
5	2	1
6	3	2

Method 2 : sort then take first of each

```
In [63]: df.sort_values(by="BBB").groupby("AAA", as_index=False).first()  
Out[63]:
```

	AAA	BBB
0	1	1
1	2	1
2	3	2

Notice the same results, with the exception of the index.

2.27.3 Multiindexing

The [multindexing](#) docs.

Creating a MultiIndex from a labeled frame

```
In [64]: df = pd.DataFrame(
    ....:     {
    ....:         "row": [0, 1, 2],
    ....:         "One_X": [1.1, 1.1, 1.1],
    ....:         "One_Y": [1.2, 1.2, 1.2],
    ....:         "Two_X": [1.11, 1.11, 1.11],
    ....:         "Two_Y": [1.22, 1.22, 1.22],
    ....:     }
    ....:
....:
```

```
In [65]: df
Out[65]:
   row  One_X  One_Y  Two_X  Two_Y
0    0      1.1    1.2    1.11   1.22
1    1      1.1    1.2    1.11   1.22
2    2      1.1    1.2    1.11   1.22

# As Labelled Index
In [66]: df = df.set_index("row")

In [67]: df
Out[67]:
   One_X  One_Y  Two_X  Two_Y
row
0      1.1    1.2    1.11   1.22
1      1.1    1.2    1.11   1.22
2      1.1    1.2    1.11   1.22

# With Hierarchical Columns
In [68]: df.columns = pd.MultiIndex.from_tuples([tuple(c.split("_")) for c in df.
   ↪columns])

In [69]: df
Out[69]:
   One          Two
   X       Y     X     Y
row
0    1.1    1.2  1.11  1.22
1    1.1    1.2  1.11  1.22
2    1.1    1.2  1.11  1.22

# Now stack & Reset
In [70]: df = df.stack(0).reset_index(1)

In [71]: df
Out[71]:
  level_1      X      Y
```

(continues on next page)

(continued from previous page)

```

row
0      One  1.10  1.20
0      Two  1.11  1.22
1      One  1.10  1.20
1      Two  1.11  1.22
2      One  1.10  1.20
2      Two  1.11  1.22

# And fix the labels (Notice the label 'level_1' got added automatically)
In [72]: df.columns = ["Sample", "All_X", "All_Y"]

In [73]: df
Out[73]:
   Sample  All_X  All_Y
row
0      One  1.10  1.20
0      Two  1.11  1.22
1      One  1.10  1.20
1      Two  1.11  1.22
2      One  1.10  1.20
2      Two  1.11  1.22

```

Arithmetic

Performing arithmetic with a MultiIndex that needs broadcasting

```

In [74]: cols = pd.MultiIndex.from_tuples(
....:     [(x, y) for x in ["A", "B", "C"] for y in ["0", "I"]]
....: )
....:

In [75]: df = pd.DataFrame(np.random.randn(2, 6), index=["n", "m"], columns=cols)

In [76]: df
Out[76]:
          A            B            C
          0            0            0
n  0.469112 -0.282863 -1.509059 -1.135632  1.212112 -0.173215
m  0.119209 -1.044236 -0.861849 -2.104569 -0.494929  1.071804

In [77]: df = df.div(df["C"], level=1)

In [78]: df
Out[78]:
          A            B            C
          0            0            0
n  0.387021  1.633022 -1.244983  6.556214  1.0  1.0
m -0.240860 -0.974279  1.741358 -1.963577  1.0  1.0

```

Slicing

Slicing a MultiIndex with xs

```
In [79]: coords = [("AA", "one"), ("AA", "six"), ("BB", "one"), ("BB", "two"), ("BB",
   ↪"six")]

In [80]: index = pd.MultiIndex.from_tuples(coords)

In [81]: df = pd.DataFrame([11, 22, 33, 44, 55], index, ["MyData"])

In [82]: df
Out[82]:
      MyData
AA one      11
      six      22
BB one      33
      two      44
      six      55
```

To take the cross section of the 1st level and 1st axis the index:

```
# Note : level and axis are optional, and default to zero
In [83]: df.xs("BB", level=0, axis=0)
Out[83]:
      MyData
one      33
two      44
six      55
```

...and now the 2nd level of the 1st axis.

```
In [84]: df.xs("six", level=1, axis=0)
Out[84]:
      MyData
AA      22
BB      55
```

Slicing a MultiIndex with xs, method #2

```
In [85]: import itertools

In [86]: index = list(itertools.product(["Ada", "Quinn", "Violet"], ["Comp", "Math", "Sci
   ↪"]))

In [87]: headr = list(itertools.product(["Exams", "Labs"], ["I", "II"]))

In [88]: idx = pd.MultiIndex.from_tuples(index, names=["Student", "Course"])

In [89]: cols = pd.MultiIndex.from_tuples(headr) # Notice these are un-named

In [90]: data = [[70 + x + y + (x * y) % 3 for x in range(4)] for y in range(9)]

In [91]: df = pd.DataFrame(data, idx, cols)
```

(continues on next page)

(continued from previous page)

In [92]: df**Out[92]:**

cumsum reset at NaN values

Replace

Using replace with backrefs

2.27.5 Grouping

The *grouping* docs.

Basic grouping with apply

Unlike agg, apply's callable is passed a sub-DataFrame which gives you access to all the columns

```
In [104]: df = pd.DataFrame(
.....    {
.....        "animal": "cat dog cat fish dog cat cat".split(),
.....        "size": list("SSMMMLL"),
.....        "weight": [8, 10, 11, 1, 20, 12, 12],
.....        "adult": [False] * 5 + [True] * 2,
.....    }
.....)
```

```
In [105]: df
```

```
Out[105]:
```

	animal	size	weight	adult
0	cat	S	8	False
1	dog	S	10	False
2	cat	M	11	False

(continues on next page)

(continued from previous page)

```

3   fish    M      1  False
4   dog     M     20  False
5   cat     L     12   True
6   cat     L     12   True

# List the size of the animals with the highest weight.
In [106]: df.groupby("animal").apply(lambda subf: subf["size"][subf["weight"].idxmax()])
Out[106]:
animal
cat      L
dog      M
fish     M
dtype: object

```

Using get_group

```
In [107]: gb = df.groupby(["animal"])
```

```
In [108]: gb.get_group("cat")
```

```
Out[108]:
animal  size  weight  adult
0       cat    S       8  False
2       cat    M      11  False
5       cat    L      12   True
6       cat    L      12   True
```

Apply to different items in a group

```

In [109]: def GrowUp(x):
.....:     avg_weight = sum(x[x["size"] == "S"].weight * 1.5)
.....:     avg_weight += sum(x[x["size"] == "M"].weight * 1.25)
.....:     avg_weight += sum(x[x["size"] == "L"].weight)
.....:     avg_weight /= len(x)
.....:     return pd.Series(["L", avg_weight, True], index=["size", "weight", "adult"])
.....:
```

```
In [110]: expected_df = gb.apply(GrowUp)
```

```
In [111]: expected_df
```

```
Out[111]:
size  weight  adult
animal
cat      L  12.4375  True
dog      L  20.0000  True
fish     L   1.2500  True
```

Expanding apply

```
In [112]: S = pd.Series([i / 100.0 for i in range(1, 11)])
```

```
In [113]: def cum_ret(x, y):
.....:     return x * (1 + y)
```

(continues on next page)

(continued from previous page)

```
....:  
  
In [114]: def red(x):  
....:     return functools.reduce(cum_ret, x, 1.0)  
....:  
  
In [115]: S.expanding().apply(red, raw=True)

```

Grouping like Python's `itertools.groupby`

```
In [143]: df = pd.DataFrame([0, 1, 0, 1, 1, 1, 0, 1, 1], columns=["A"])
```

```
In [144]: df["A"].groupby((df["A"] != df["A"].shift()).cumsum()).groups
Out[144]: {1: [0], 2: [1], 3: [2], 4: [3, 4, 5], 5: [6], 6: [7, 8]}
```

```
In [145]: df["A"].groupby((df["A"] != df["A"].shift()).cumsum()).cumsum()
```

```
Out[145]:
```

```
0    0
1    1
2    0
3    1
4    2
5    3
6    0
7    1
8    2
Name: A, dtype: int64
```

Expanding data

Alignment and to-date

Rolling Computation window based on values instead of counts

Rolling Mean by Time Interval

Splitting

Splitting a frame

Create a list of dataframes, split using a delineation based on logic included in rows.

```
In [146]: df = pd.DataFrame(  
.....:     data={  
.....:         "Case": ["A", "A", "A", "B", "A", "A", "B", "A", "A"],  
.....:         "Data": np.random.randn(9),  
.....:     }  
.....: )  
.....:  
  
In [147]: dfs = list(  
.....:     zip(  
.....:         *df.groupby(  
.....:             (1 * (df["Case"] == "B"))  
.....:             .cumsum()  
.....:             .rolling(window=3, min_periods=1)  
.....:             .median()  
.....:         )  
.....:     )  
.....: )[-1]  
.....:  
  
In [148]: dfs[0]  
Out[148]:  
   Case      Data

2.27.6 Timeseries

Between times

Using indexer between time

Constructing a datetime range that excludes weekends and includes only certain times

Vectorized Lookup

Aggregation and plotting time series

Turn a matrix with hours in columns and days in rows into a continuous row sequence in the form of a time series. How to rearrange a Python pandas DataFrame?

Dealing with duplicates when reindexing a timeseries to a specified frequency

Calculate the first day of the month for each entry in a DatetimeIndex

```
In [175]: dates = pd.date_range("2000-01-01", periods=5)
```

```
In [176]: dates.to_period(freq="M").to_timestamp()
```

```
Out[176]:
```

```
DatetimeIndex(['2000-01-01', '2000-01-01', '2000-01-01', '2000-01-01',
                 '2000-01-01'],
                dtype='datetime64[ns]', freq=None)
```

Resampling

The *Resample* docs.

Using Grouper instead of TimeGrouper for time grouping of values

Time grouping with some missing values

Valid frequency arguments to Grouper *Timeseries*

Grouping using a MultiIndex

Using TimeGrouper and another grouping to create subgroups, then apply a custom function GH3791

Resampling with custom periods

Resample intraday frame without adding new days

Resample minute data

Resample with groupby

2.27.7 Merge

The *Join* docs.

Concatenate two dataframes with overlapping index (emulate R rbind)

```
In [177]: rng = pd.date_range("2000-01-01", periods=6)
```

```
In [178]: df1 = pd.DataFrame(np.random.randn(6, 3), index=rng, columns=["A", "B", "C"])
```

```
In [179]: df2 = df1.copy()
```

Depending on df construction, ignore_index may be needed

```
In [180]: df = pd.concat([df1, df2], ignore_index=True)
```

```
In [181]: df
```

```
Out[181]:
```

```

2.27.9 Data in/out

Performance comparison of SQL vs HDF5

CSV

The [CSV](#) docs

`read_csv` in action

appending to a csv

Reading a csv chunk-by-chunk

Reading only certain rows of a csv chunk-by-chunk

Reading the first few lines of a frame

Reading a file that is compressed but not by gzip/bz2 (the native compressed formats which `read_csv` understands). This example shows a WinZipped file, but is a general application of opening the file within a context manager and using that handle to read. See [here](#)

`Inferring dtypes` from a file

Dealing with bad lines [GH2886](#)

Write a multi-row index CSV without writing duplicates

Reading multiple files to create a single DataFrame

The best way to combine multiple files into a single DataFrame is to read the individual frames one by one, put all of the individual frames into a list, and then combine the frames in the list using `pd.concat()`:

```
In [189]: for i in range(3):
....:     data = pd.DataFrame(np.random.randn(10, 4))
....:     data.to_csv("file_{}.csv".format(i))
....:

In [190]: files = ["file_0.csv", "file_1.csv", "file_2.csv"]

In [191]: result = pd.concat([pd.read_csv(f) for f in files], ignore_index=True)
```

You can use the same approach to read all files matching a pattern. Here is an example using `glob`:

```
In [192]: import glob

In [193]: import os

In [194]: files = glob.glob("file_*.csv")

In [195]: result = pd.concat([pd.read_csv(f) for f in files], ignore_index=True)
```

Finally, this strategy will work with the other `pd.read_*`(...) functions described in the [io docs](#).

Parsing date components in multi-columns

Parsing date components in multi-columns is faster with a format

```
In [196]: i = pd.date_range("20000101", periods=10000)

In [197]: df = pd.DataFrame({"year": i.year, "month": i.month, "day": i.day})

In [198]: df.head()
Out[198]:
   year  month  day
0    2000      1    1
1    2000      1    2
2    2000      1    3
3    2000      1    4
4    2000      1    5

In [199]: %timeit pd.to_datetime(df.year * 10000 + df.month * 100 + df.day, format='%Y%m%d')
....: ds = df.apply(lambda x: "%04d%02d%02d" % (x["year"], x["month"], x["day"])), axis=1
....: ds.head()
....: %timeit pd.to_datetime(ds)
....:
```

(continues on next page)

```

Option 1: pass rows explicitly to skip rows

In [201]: `from io import StringIO`

```
In [202]: pd.read_csv(  
.....:     StringIO(data),  
.....:     sep="; ",  
.....:     skiprows=[11, 12],  
.....:     index_col=0,  
.....:     parse_dates=True,  
.....:     header=10,  
.....: )
```

	Param1	Param2	Param4	Param5
date				
1990-01-01 00:00:00	1	1	2	3
1990-01-01 01:00:00	5	3	4	5
1990-01-01 02:00:00	9	5	6	7
1990-01-01 03:00:00	13	7	8	9
1990-01-01 04:00:00	17	9	10	11
1990-01-01 05:00:00	21	11	12	13

Option 2: read column names and then data

```
In [203]: pd.read_csv(StringIO(data), sep=";", header=10, nrows=10).columns
Out[203]: Index(['date', 'Param1', 'Param2', 'Param4', 'Param5'], dtype='object')

In [204]: columns = pd.read_csv(StringIO(data), sep=";", header=10, nrows=10).columns

In [205]: pd.read_csv(
    .....:     StringIO(data), sep=";", index_col=0, header=12, parse_dates=True, ↴
    ↪names=columns
    .....: )
    .....:

Out[205]:
      Param1  Param2  Param4  Param5
date
1990-01-01 00:00:00      1      1      2      3
1990-01-01 01:00:00      5      3      4      5
1990-01-01 02:00:00      9      5      6      7
1990-01-01 03:00:00     13      7      8      9
1990-01-01 04:00:00     17      9     10     11
1990-01-01 05:00:00     21     11     12     13

Groupby on a HDFStore with high group density

Hierarchical queries on a HDFStore

Counting with a HDFStore

Troubleshoot HDFStore exceptions

Setting min_itemsize with strings

Using ptrepak to create a completely-sorted-index on a store

Storing Attributes to a group node

```
In [206]: df = pd.DataFrame(np.random.randn(8, 3))

In [207]: store = pd.HDFStore("test.h5")

In [208]: store.put("df", df)

# you can store an arbitrary Python object via pickle
In [209]: store.get_storer("df").attrs.my_attribute = {"A": 10}

In [210]: store.get_storer("df").attrs.my_attribute
Out[210]: {'A': 10}
```

You can create or load a HDFStore in-memory by passing the driver parameter to PyTables. Changes are only written to disk when the HDFStore is closed.

```
In [211]: store = pd.HDFStore("test.h5", "w", driver="H5FD_CORE")

In [212]: df = pd.DataFrame(np.random.randn(8, 3))

In [213]: store["test"] = df

# only after closing the store, data is written to disk:
In [214]: store.close()
```

Binary files

pandas readily accepts NumPy record arrays, if you need to read in a binary file consisting of an array of C structs. For example, given this C program in a file called `main.c` compiled with `gcc main.c -std=gnu99` on a 64-bit machine,

```
#include <stdio.h>
#include <stdint.h>

typedef struct _Data
{
    int32_t count;
    double avg;
    float scale;
} Data;

int main(int argc, const char *argv[])
{
    size_t n = 10;
    Data d[n];

    for (int i = 0; i < n; ++i)
    {
        d[i].count = i;
        d[i].avg = i + 1.0;
        d[i].scale = (float) i + 2.0f;
    }

    FILE *file = fopen("binary.dat", "wb");
    fwrite(&d, sizeof(Data), n, file);
    fclose(file);

    return 0;
}
```

the following Python code will read the binary file 'binary.dat' into a pandas DataFrame, where each element of the struct corresponds to a column in the frame:

```
names = "count", "avg", "scale"

# note that the offsets are larger than the size of the type because of
# struct padding
offsets = 0, 8, 16
formats = "i4", "f8", "f4"
dt = np.dtype({ "names": names, "offsets": offsets, "formats": formats}, align=True)
df = pd.DataFrame(np.fromfile("binary.dat", dt))
```

Note: The offsets of the structure elements may be different depending on the architecture of the machine on which the file was created. Using a raw binary file format like this for general data storage is not recommended, as it is not cross platform. We recommend either HDF5 or parquet, both of which are supported by pandas' IO facilities.

2.27.10 Computation

Numerical integration (sample-based) of a time series

Correlation

Often it's useful to obtain the lower (or upper) triangular form of a correlation matrix calculated from `DataFrame.corr()`. This can be achieved by passing a boolean mask to `where` as follows:

```
In [215]: df = pd.DataFrame(np.random.random(size=(100, 5)))

In [216]: corr_mat = df.corr()

In [217]: mask = np.tril(np.ones_like(corr_mat, dtype=np.bool_), k=-1)

In [218]: corr_mat.where(mask)
Out[218]:
      0         1         2         3         4
0    NaN       NaN       NaN       NaN       NaN
1 -0.079861   NaN       NaN       NaN       NaN
2 -0.236573  0.183801   NaN       NaN       NaN
3 -0.013795 -0.051975  0.037235   NaN       NaN
4 -0.031974  0.118342 -0.073499 -0.02063  NaN
```

The `method` argument within `DataFrame.corr` can accept a callable in addition to the named correlation types. Here we compute the `distance` correlation matrix for a `DataFrame` object.

```
In [219]: def distcorr(x, y):
    ....:     n = len(x)
    ....:     a = np.zeros(shape=(n, n))
    ....:     b = np.zeros(shape=(n, n))
    ....:     for i in range(n):
    ....:         for j in range(i + 1, n):
    ....:             a[i, j] = abs(x[i] - x[j])
    ....:             b[i, j] = abs(y[i] - y[j])
    ....:     a += a.T
    ....:     b += b.T
    ....:     a_bar = np.vstack([np.nanmean(a, axis=0)] * n)
    ....:     b_bar = np.vstack([np.nanmean(b, axis=0)] * n)
    ....:     A = a - a_bar - a_bar.T + np.full(shape=(n, n), fill_value=a_bar.mean())
    ....:     B = b - b_bar - b_bar.T + np.full(shape=(n, n), fill_value=b_bar.mean())
    ....:     cov_ab = np.sqrt(np.nansum(A * B)) / n
    ....:     std_a = np.sqrt(np.sqrt(np.nansum(A ** 2)) / n)
    ....:     std_b = np.sqrt(np.sqrt(np.nansum(B ** 2)) / n)
    ....:     return cov_ab / std_a / std_b
    ....:

In [220]: df = pd.DataFrame(np.random.normal(size=(100, 3)))

In [221]: df.corr(method=distcorr)
Out[221]:
      0         1         2
0  1.000000  0.197613  0.216328

```
0      NaT  
1      NaT  
2    1 days  
dtype: timedelta64[ns]
```

2.27.12 Creating example data

To create a dataframe from every combination of some given values, like R's `expand.grid()` function, we can create a dict where the keys are column names and the values are lists of the data values:

```
In [241]: def expand_grid(data_dict):  
.....:     rows = itertools.product(*data_dict.values())  
.....:     return pd.DataFrame.from_records(rows, columns=data_dict.keys())  
.....:  
  
In [242]: df = expand_grid(  
.....:     {"height": [60, 70], "weight": [100, 140, 180], "sex": ["Male", "Female"]})  
.....:  
.....:  
  
In [243]: df  
Out[243]:
```

	height	weight	sex
0	60	100	Male
1	60	100	Female
2	60	140	Male
3	60	140	Female
4	60	180	Male
5	60	180	Female
6	70	100	Male
7	70	100	Female
8	70	140	Male
9	70	140	Female
10	70	180	Male
11	70	180	Female

API REFERENCE

This page gives an overview of all public pandas objects, functions and methods. All classes and functions exposed in `pandas.*` namespace are public.

Some subpackages are public which include `pandas.errors`, `pandas.plotting`, and `pandas.testing`. Public functions in `pandas.io` and `pandas.tseries` submodules are mentioned in the documentation. `pandas.api.types` subpackage holds some public functions related to data types in pandas.

Warning: The `pandas.core`, `pandas.compat`, and `pandas.util` top-level modules are PRIVATE. Stable functionality in such modules is not guaranteed.

3.1 Input/output

3.1.1 Pickling

<code>read_pickle(filepath_or_buffer[, ...])</code>	Load pickled pandas object (or any object) from file.
<code>DataFrame.to_pickle(path[, compression, ...])</code>	Pickle (serialize) object to file.

`pandas.read_pickle`

`pandas.read_pickle(filepath_or_buffer, compression='infer', storage_options=None)`
Load pickled pandas object (or any object) from file.

Warning: Loading pickled data received from untrusted sources can be unsafe. See [here](#).

Parameters

filepath_or_buffer [str, path object, or file-like object] String, path object (implementing `os.PathLike[str]`), or file-like object implementing a binary `readlines()` function.

Changed in version 1.0.0: Accept URL. URL is not limited to S3 and GCS.

compression [str or dict, default ‘infer’] For on-the-fly decompression of on-disk data. If ‘infer’ and ‘filepath_or_buffer’ is path-like, then detect compression from the following extensions: ‘.gz’, ‘.bz2’, ‘.zip’, ‘.xz’, or ‘.zst’ (otherwise no compression). If using ‘zip’, the ZIP file must contain only one data file to be read in. Set to None for no decompression. Can also be a dict with key ‘method’ set to one of {‘zip’, ‘gzip’, ‘bz2’,

'zstd'} and other key-value pairs are forwarded to `zipfile.ZipFile`, `gzip.GzipFile`, `bz2.BZ2File`, or `zstandard.ZstdDecompressor`, respectively. As an example, the following could be passed for Zstandard decompression using a custom compression dictionary: `compression={'method': 'zstd', 'dict_data': my_compression_dict}`.

Changed in version 1.4.0: Zstandard support.

storage_options [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to `urllib` as header options. For other URLs (e.g. starting with “`s3://`”, and “`gcs://`”) the key-value pairs are forwarded to `fsspec`. Please see `fsspec` and `urllib` for more details.

New in version 1.2.0.

Returns

unpickled [same type as object stored in file]

See also:

`DataFrame.to_pickle` Pickle (serialize) DataFrame object to file.

`Series.to_pickle` Pickle (serialize) Series object to file.

`read_hdf` Read HDF5 file into a DataFrame.

`read_sql` Read SQL query or database table into a DataFrame.

`read_parquet` Load a parquet object, returning a DataFrame.

Notes

`read_pickle` is only guaranteed to be backwards compatible to pandas 0.20.3.

Examples

```
>>> original_df = pd.DataFrame({'foo': range(5), "bar": range(5, 10)})
>>> original_df
   foo    bar
0     0      5
1     1      6
2     2      7
3     3      8
4     4      9
>>> pd.to_pickle(original_df, "./dummy.pkl")
```

```
>>> unpickled_df = pd.read_pickle("./dummy.pkl")
>>> unpickled_df
   foo    bar
0     0      5
1     1      6
2     2      7
3     3      8
4     4      9
```

pandas.DataFrame.to_pickle

`DataFrame.to_pickle(path, compression='infer', protocol=5, storage_options=None)`
 Pickle (serialize) object to file.

Parameters

path [str] File path where the pickled object will be stored.

compression [str or dict, default ‘infer’] For on-the-fly compression of the output data. If ‘infer’ and ‘path’ path-like, then detect compression from the following extensions: ‘.gz’, ‘.bz2’, ‘.zip’, ‘.xz’, or ‘.zst’ (otherwise no compression). Set to None for no compression. Can also be a dict with key ‘method’ set to one of {‘zip’, ‘gzip’, ‘bz2’, ‘zstd’} and other key-value pairs are forwarded to `zipfile.ZipFile`, `gzip.GzipFile`, `bz2.BZ2File`, or `zstandard.ZstdDecompressor`, respectively. As an example, the following could be passed for faster compression and to create a reproducible gzip archive: `compression={‘method’: ‘gzip’, ‘compresslevel’: 1, ‘mtime’: 1}`.

protocol [int] Int which indicates which protocol should be used by the pickler, default HIGH-EST_PROTOCOL (see [1] paragraph 12.1.2). The possible values are 0, 1, 2, 3, 4, 5. A negative value for the protocol parameter is equivalent to setting its value to HIGH-EST_PROTOCOL.

storage_options [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to `urllib` as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to `fsspec`. Please see `fsspec` and `urllib` for more details.

New in version 1.2.0.

See also:

`read_pickle` Load pickled pandas object (or any object) from file.

`DataFrame.to_hdf` Write DataFrame to an HDF5 file.

`DataFrame.to_sql` Write DataFrame to a SQL database.

`DataFrame.to_parquet` Write a DataFrame to the binary parquet format.

Examples

```
>>> original_df = pd.DataFrame({“foo”: range(5), “bar”: range(5, 10)})
>>> original_df
   foo  bar
0    0    5
1    1    6
2    2    7
3    3    8
4    4    9
>>> original_df.to_pickle("./dummy.pkl")
```

```
>>> unpickled_df = pd.read_pickle("./dummy.pkl")
>>> unpickled_df
   foo  bar
0    0    5
```

3.1.2 Flat file

<code>read_table(filepath_or_buffer[, sep, ...])</code>	Read general delimited file into DataFrame.
<code>read_csv(filepath_or_buffer[, sep, ...])</code>	Read a comma-separated values (csv) file into DataFrame.
<code>DataFrame.to_csv([path_or_buf, sep, na_rep, ...])</code>	Write object to a comma-separated values (csv) file.
<code>read_fwf(filepath_or_buffer[, colspecs, ...])</code>	Read a table of fixed-width formatted lines into DataFrame.

pandas.read_table

```
pandas.read_table(filepath_or_buffer, sep=NoDefault.no_default, delimiter=None, header='infer',
                  names=NoDefault.no_default, index_col=None, usecols=None, squeeze=None,
                  prefix=NoDefault.no_default, mangle_dupe_cols=True, dtype=None, engine=None,
                  converters=None, true_values=None, false_values=None, skipinitialspace=False,
                  skiprows=None, skipfooter=0, nrows=None, na_values=None, keep_default_na=True,
                  na_filter=True, verbose=False, skip_blank_lines=True, parse_dates=False,
                  infer_datetime_format=False, keep_date_col=False, date_parser=None, dayfirst=False,
                  cache_dates=True, iterator=False, chunksize=None, compression='infer', thousands=None,
                  decimal=',', lineterminator=None, quotechar='"', quoting=0, doublequote=True,
                  escapechar=None, comment=None, encoding=None, encoding_errors='strict',
                  dialect=None, error_bad_lines=None, warn_bad_lines=None, on_bad_lines=None,
                  delim_whitespace=False, low_memory=True, memory_map=False, float_precision=None,
                  storage_options=None)
```

Read general delimited file into DataFrame.

Also supports optionally iterating or breaking of the file into chunks.

Additional help can be found in the online docs for [IO Tools](#).

Parameters

filepath_or_buffer [str, path object or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, gs, and file. For file URLs, a host is expected. A local file could be: `file://localhost/path/to/table.csv`.

If you want to pass in a path object, pandas accepts any `os.PathLike`.

By file-like object, we refer to objects with a `read()` method, such as a file handle (e.g. via builtin `open` function) or `StringIO`.

sep [str, default '\t' (tab-stop)] Delimiter to use. If sep is None, the C engine cannot automatically detect the separator, but the Python parsing engine can, meaning the latter will be used and automatically detect the separator by Python's builtin sniffer tool, `csv.Sniffer`. In addition, separators longer than 1 character and different from '\s+' will be interpreted as regular expressions and will also force the use of the Python parsing engine. Note that regex delimiters are prone to ignoring quoted data. Regex example: '\r\t'.

delimiter [str, default None] Alias for sep.

header [int, list of int, None, default ‘infer’] Row number(s) to use as the column names, and the start of the data. Default behavior is to infer the column names: if no names are passed the behavior is identical to header=0 and column names are inferred from the first line of the file, if column names are passed explicitly then the behavior is identical to header=None. Explicitly pass header=0 to be able to replace existing names. The header can be a list of integers that specify row locations for a multi-index on the columns e.g. [0,1,3]. Intervening rows that are not specified will be skipped (e.g. 2 in this example is skipped). Note that this parameter ignores commented lines and empty lines if skip_blank_lines=True, so header=0 denotes the first line of data rather than the first line of the file.

names [array-like, optional] List of column names to use. If the file contains a header row, then you should explicitly pass header=0 to override the column names. Duplicates in this list are not allowed.

index_col [int, str, sequence of int / str, or False, optional, default None] Column(s) to use as the row labels of the DataFrame, either given as string name or column index. If a sequence of int / str is given, a MultiIndex is used.

Note: `index_col=False` can be used to force pandas to *not* use the first column as the index, e.g. when you have a malformed file with delimiters at the end of each line.

usecols [list-like or callable, optional] Return a subset of the columns. If list-like, all elements must either be positional (i.e. integer indices into the document columns) or strings that correspond to column names provided either by the user in `names` or inferred from the document header row(s). If `names` are given, the document header row(s) are not taken into account. For example, a valid list-like `usecols` parameter would be [0, 1, 2] or ['foo', 'bar', 'baz']. Element order is ignored, so `usecols=[0, 1]` is the same as [1, 0]. To instantiate a DataFrame from data with element order preserved use `pd.read_csv(data, usecols=['foo', 'bar'])[['foo', 'bar']]` for columns in ['foo', 'bar'] order or `pd.read_csv(data, usecols=['foo', 'bar'])[['bar', 'foo']]` for ['bar', 'foo'] order.

If callable, the callable function will be evaluated against the column names, returning names where the callable function evaluates to True. An example of a valid callable argument would be `lambda x: x.upper() in ['AAA', 'BBB', 'DDD']`. Using this parameter results in much faster parsing time and lower memory usage.

squeeze [bool, default False] If the parsed data only contains one column then return a Series.

Deprecated since version 1.4.0: Append `.squeeze("columns")` to the call to `read_table` to squeeze the data.

prefix [str, optional] Prefix to add to column numbers when no header, e.g. ‘X’ for X0, X1, ...

Deprecated since version 1.4.0: Use a list comprehension on the DataFrame’s columns after calling `read_csv`.

mangle_dupe_cols [bool, default True] Duplicate columns will be specified as ‘X’, ‘X.1’, ... ‘X.N’, rather than ‘X’...‘X’. Passing in False will cause data to be overwritten if there are duplicate names in the columns.

dtype [Type name or dict of column -> type, optional] Data type for data or columns. E.g. {‘a’: np.float64, ‘b’: np.int32, ‘c’: ‘Int64’} Use `str` or `object` together with suitable `na_values` settings to preserve and not interpret `dtype`. If converters are specified, they will be applied INSTEAD of `dtype` conversion.

engine [{‘c’, ‘python’, ‘pyarrow’}, optional] Parser engine to use. The C and pyarrow engines are faster, while the python engine is currently more feature-complete. Multithreading is

currently only supported by the pyarrow engine.

New in version 1.4.0: The “pyarrow” engine was added as an *experimental* engine, and some features are unsupported, or may not work correctly, with this engine.

converters [dict, optional] Dict of functions for converting values in certain columns. Keys can either be integers or column labels.

true_values [list, optional] Values to consider as True.

false_values [list, optional] Values to consider as False.

skipinitialspace [bool, default False] Skip spaces after delimiter.

skiprows [list-like, int or callable, optional] Line numbers to skip (0-indexed) or number of lines to skip (int) at the start of the file.

If callable, the callable function will be evaluated against the row indices, returning True if the row should be skipped and False otherwise. An example of a valid callable argument would be `lambda x: x in [0, 2]`.

skipfooter [int, default 0] Number of lines at bottom of file to skip (Unsupported with engine='c').

nrows [int, optional] Number of rows of file to read. Useful for reading pieces of large files.

na_values [scalar, str, list-like, or dict, optional] Additional strings to recognize as NA/NaN. If dict passed, specific per-column NA values. By default the following values are interpreted as NaN: ‘’, ‘#N/A’, ‘#N/A N/A’, ‘#NA’, ‘-1.#IND’, ‘-1.#QNAN’, ‘-NaN’, ‘-nan’, ‘1.#IND’, ‘1.#QNAN’, ‘<NA>’, ‘N/A’, ‘NA’, ‘NULL’, ‘NaN’, ‘n/a’, ‘nan’, ‘null’.

keep_default_na [bool, default True] Whether or not to include the default NaN values when parsing the data. Depending on whether *na_values* is passed in, the behavior is as follows:

- If *keep_default_na* is True, and *na_values* are specified, *na_values* is appended to the default NaN values used for parsing.
- If *keep_default_na* is True, and *na_values* are not specified, only the default NaN values are used for parsing.
- If *keep_default_na* is False, and *na_values* are specified, only the NaN values specified *na_values* are used for parsing.
- If *keep_default_na* is False, and *na_values* are not specified, no strings will be parsed as NaN.

Note that if *na_filter* is passed in as False, the *keep_default_na* and *na_values* parameters will be ignored.

na_filter [bool, default True] Detect missing value markers (empty strings and the value of *na_values*). In data without any NAs, passing *na_filter*=False can improve the performance of reading a large file.

verbose [bool, default False] Indicate number of NA values placed in non-numeric columns.

skip_blank_lines [bool, default True] If True, skip over blank lines rather than interpreting as NaN values.

parse_dates [bool or list of int or names or list of lists or dict, default False] The behavior is as follows:

- boolean. If True -> try parsing the index.
- list of int or names. e.g. If [1, 2, 3] -> try parsing columns 1, 2, 3 each as a separate date column.

- list of lists. e.g. If `[[1, 3]]` -> combine columns 1 and 3 and parse as a single date column.
- dict, e.g. `{'foo' : [1, 3]}` -> parse columns 1, 3 as date and call result 'foo'

If a column or index cannot be represented as an array of datetimes, say because of an unparsable value or a mixture of timezones, the column or index will be returned unaltered as an object data type. For non-standard datetime parsing, use `pd.to_datetime` after `pd.read_csv`. To parse an index or column with a mixture of timezones, specify `date_parser` to be a partially-applied `pandas.to_datetime()` with `utc=True`. See [Parsing a CSV with mixed timezones](#) for more.

Note: A fast-path exists for iso8601-formatted dates.

infer_datetime_format [bool, default False] If True and `parse_dates` is enabled, pandas will attempt to infer the format of the datetime strings in the columns, and if it can be inferred, switch to a faster method of parsing them. In some cases this can increase the parsing speed by 5-10x.

keep_date_col [bool, default False] If True and `parse_dates` specifies combining multiple columns then keep the original columns.

date_parser [function, optional] Function to use for converting a sequence of string columns to an array of datetime instances. The default uses `dateutil.parser.parser` to do the conversion. Pandas will try to call `date_parser` in three different ways, advancing to the next if an exception occurs: 1) Pass one or more arrays (as defined by `parse_dates`) as arguments; 2) concatenate (row-wise) the string values from the columns defined by `parse_dates` into a single array and pass that; and 3) call `date_parser` once for each row using one or more strings (corresponding to the columns defined by `parse_dates`) as arguments.

dayfirst [bool, default False] DD/MM format dates, international and European format.

cache_dates [bool, default True] If True, use a cache of unique, converted dates to apply the datetime conversion. May produce significant speed-up when parsing duplicate date strings, especially ones with timezone offsets.

New in version 0.25.0.

iterator [bool, default False] Return `TextFileReader` object for iteration or getting chunks with `get_chunk()`.

Changed in version 1.2: `TextFileReader` is a context manager.

chunksize [int, optional] Return `TextFileReader` object for iteration. See the [IO Tools](#) docs for more information on `iterator` and `chunksize`.

Changed in version 1.2: `TextFileReader` is a context manager.

compression [str or dict, default 'infer'] For on-the-fly decompression of on-disk data. If 'infer' and '%s' is path-like, then detect compression from the following extensions: '.gz', '.bz2', '.zip', '.xz', or '.zst' (otherwise no compression). If using 'zip', the ZIP file must contain only one data file to be read in. Set to None for no decompression. Can also be a dict with key 'method' set to one of {'zip', 'gzip', 'bz2', 'zstd'} and other key-value pairs are forwarded to `zipfile.ZipFile`, `gzip.GzipFile`, `bz2.BZ2File`, or `zstandard.ZstdDecompressor`, respectively. As an example, the following could be passed for Zstandard decompression using a custom compression dictionary: `compression={'method': 'zstd', 'dict_data': my_compression_dict}`.

Changed in version 1.4.0: Zstandard support.

thousands [str, optional] Thousands separator.

decimal [str, default '.'] Character to recognize as decimal point (e.g. use ',' for European data).

lineterminator [str (length 1), optional] Character to break file into lines. Only valid with C parser.

quotechar [str (length 1), optional] The character used to denote the start and end of a quoted item. Quoted items can include the delimiter and it will be ignored.

quoting [int or csv.QUOTE_* instance, default 0] Control field quoting behavior per csv.QUOTE_* constants. Use one of QUOTE_MINIMAL (0), QUOTE_ALL (1), QUOTE_NONNUMERIC (2) or QUOTE_NONE (3).

doublequote [bool, default True] When quotechar is specified and quoting is not QUOTE_NONE, indicate whether or not to interpret two consecutive quotechar elements INSIDE a field as a single quotechar element.

escapechar [str (length 1), optional] One-character string used to escape other characters.

comment [str, optional] Indicates remainder of line should not be parsed. If found at the beginning of a line, the line will be ignored altogether. This parameter must be a single character. Like empty lines (as long as skip_blank_lines=True), fully commented lines are ignored by the parameter *header* but not by skiprows. For example, if `comment='#'`, parsing `#empty\na,b,c\n1,2,3` with `header=0` will result in ‘a,b,c’ being treated as the header.

encoding [str, optional] Encoding to use for UTF when reading/writing (ex. ‘utf-8’). [List of Python standard encodings](#).

Changed in version 1.2: When encoding is None, errors="replace" is passed to open(). Otherwise, errors="strict" is passed to open(). This behavior was previously only the case for engine="python".

Changed in version 1.3.0: `encoding_errors` is a new argument. `encoding` has no longer an influence on how encoding errors are handled.

encoding_errors [str, optional, default “strict”] How encoding errors are treated. [List of possible values](#).

New in version 1.3.0.

dialect [str or csv.Dialect, optional] If provided, this parameter will override values (default or not) for the following parameters: *delimiter*, *doublequote*, *escapechar*, *skipinitialspace*, *quotechar*, and *quoting*. If it is necessary to override values, a ParserWarning will be issued. See csv.Dialect documentation for more details.

error_bad_lines [bool, optional, default None] Lines with too many fields (e.g. a csv line with too many commas) will by default cause an exception to be raised, and no DataFrame will be returned. If False, then these “bad lines” will be dropped from the DataFrame that is returned.

Deprecated since version 1.3.0: The `on_bad_lines` parameter should be used instead to specify behavior upon encountering a bad line instead.

warn_bad_lines [bool, optional, default None] If `error_bad_lines` is False, and `warn_bad_lines` is True, a warning for each “bad line” will be output.

Deprecated since version 1.3.0: The `on_bad_lines` parameter should be used instead to specify behavior upon encountering a bad line instead.

on_bad_lines [{‘error’, ‘warn’, ‘skip’} or callable, default ‘error’] Specifies what to do upon encountering a bad line (a line with too many fields). Allowed values are :

- ‘error’, raise an Exception when a bad line is encountered.
- ‘warn’, raise a warning when a bad line is encountered and skip that line.

- ‘skip’, skip bad lines without raising or warning when they are encountered.

New in version 1.3.0:

- callable, function with signature `(bad_line: list[str]) -> list[str] | None` that will process a single bad line. `bad_line` is a list of strings split by the `sep`. If the function returns `None`, the bad line will be ignored. If the function returns a new list of strings with more elements than expected, a `ParserWarning` will be emitted while dropping extra elements. Only supported when `engine="python"`

New in version 1.4.0.

delim_whitespace [bool, default False] Specifies whether or not whitespace (e.g. ' ' or '\r') will be used as the `sep`. Equivalent to setting `sep='\s+'`. If this option is set to True, nothing should be passed in for the `delimiter` parameter.

low_memory [bool, default True] Internally process the file in chunks, resulting in lower memory use while parsing, but possibly mixed type inference. To ensure no mixed types either set `False`, or specify the type with the `dtype` parameter. Note that the entire file is read into a single `DataFrame` regardless, use the `chunksize` or `iterator` parameter to return the data in chunks. (Only valid with C parser).

memory_map [bool, default False] If a filepath is provided for `filepath_or_buffer`, map the file object directly onto memory and access the data directly from there. Using this option can improve performance because there is no longer any I/O overhead.

float_precision [str, optional] Specifies which converter the C engine should use for floating-point values. The options are `None` or ‘high’ for the ordinary converter, ‘legacy’ for the original lower precision pandas converter, and ‘round_trip’ for the round-trip converter.

Changed in version 1.2.

storage_options [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to `urllib` as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to `fsspec`. Please see `fsspec` and `urllib` for more details.

New in version 1.2.

Returns

DataFrame or TextParser A comma-separated values (csv) file is returned as two-dimensional data structure with labeled axes.

See also:

[`DataFrame.to_csv`](#) Write DataFrame to a comma-separated values (csv) file.

[`read_csv`](#) Read a comma-separated values (csv) file into DataFrame.

[`read_fwf`](#) Read a table of fixed-width formatted lines into DataFrame.

Examples

```
>>> pd.read_table('data.csv')
```

pandas.read_csv

```
pandas.read_csv(filepath_or_buffer, sep=NoDefault.no_default, delimiter=None, header='infer',
                 names=NoDefault.no_default, index_col=None, usecols=None, squeeze=None,
                 prefix=NoDefault.no_default, mangle_dupe_cols=True, dtype=None, engine=None,
                 converters=None, true_values=None, false_values=None, skipinitialspace=False,
                 skiprows=None, skipfooter=0, nrows=None, na_values=None, keep_default_na=True,
                 na_filter=True, verbose=False, skip_blank_lines=True, parse_dates=None,
                 infer_datetime_format=False, keep_date_col=False, date_parser=None, dayfirst=False,
                 cache_dates=True, iterator=False, chunksize=None, compression='infer', thousands=None,
                 decimal=',', lineterminator=None, quotechar='"', quoting=0, doublequote=True,
                 escapechar=None, comment=None, encoding=None, encoding_errors='strict', dialect=None,
                 error_bad_lines=None, warn_bad_lines=None, on_bad_lines=None, delim_whitespace=False,
                 low_memory=True, memory_map=False, float_precision=None, storage_options=None)
```

Read a comma-separated values (csv) file into DataFrame.

Also supports optionally iterating or breaking of the file into chunks.

Additional help can be found in the online docs for [IO Tools](#).

Parameters

filepath_or_buffer [str, path object or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, gs, and file. For file URLs, a host is expected. A local file could be: <file:///localhost/path/to/table.csv>.

If you want to pass in a path object, pandas accepts any [os.PathLike](#).

By file-like object, we refer to objects with a `read()` method, such as a file handle (e.g. via `builtin open` function) or `StringIO`.

sep [str, default ','] Delimiter to use. If `sep` is None, the C engine cannot automatically detect the separator, but the Python parsing engine can, meaning the latter will be used and automatically detect the separator by Python's builtin sniffer tool, `csv.Sniffer`. In addition, separators longer than 1 character and different from '\s+' will be interpreted as regular expressions and will also force the use of the Python parsing engine. Note that regex delimiters are prone to ignoring quoted data. Regex example: '\r\t'.

delimiter [str, default None] Alias for `sep`.

header [int, list of int, None, default 'infer'] Row number(s) to use as the column names, and the start of the data. Default behavior is to infer the column names: if no names are passed the behavior is identical to `header=0` and column names are inferred from the first line of the file, if column names are passed explicitly then the behavior is identical to `header=None`. Explicitly pass `header=0` to be able to replace existing names. The header can be a list of integers that specify row locations for a multi-index on the columns e.g. [0,1,3]. Intervening rows that are not specified will be skipped (e.g. 2 in this example is skipped). Note that this parameter ignores commented lines and empty lines if `skip_blank_lines=True`, so `header=0` denotes the first line of data rather than the first line of the file.

names [array-like, optional] List of column names to use. If the file contains a header row, then you should explicitly pass `header=0` to override the column names. Duplicates in this list are not allowed.

index_col [int, str, sequence of int / str, or False, optional, default None] Column(s) to use as the row labels of the DataFrame, either given as string name or column index. If a sequence of int / str is given, a MultiIndex is used.

Note: `index_col=False` can be used to force pandas to *not* use the first column as the index, e.g. when you have a malformed file with delimiters at the end of each line.

usecols [list-like or callable, optional] Return a subset of the columns. If list-like, all elements must either be positional (i.e. integer indices into the document columns) or strings that correspond to column names provided either by the user in `names` or inferred from the document header row(s). If `names` are given, the document header row(s) are not taken into account. For example, a valid list-like `usecols` parameter would be `[0, 1, 2]` or `['foo', 'bar', 'baz']`. Element order is ignored, so `usecols=[0, 1]` is the same as `[1, 0]`. To instantiate a DataFrame from data with element order preserved use `pd.read_csv(data, usecols=['foo', 'bar'])[['foo', 'bar']]` for columns in `['foo', 'bar']` order or `pd.read_csv(data, usecols=['foo', 'bar'])[['bar', 'foo']]` for `['bar', 'foo']` order.

If callable, the callable function will be evaluated against the column names, returning names where the callable function evaluates to True. An example of a valid callable argument would be `lambda x: x.upper() in ['AAA', 'BBB', 'DDD']`. Using this parameter results in much faster parsing time and lower memory usage.

squeeze [bool, default False] If the parsed data only contains one column then return a Series.

Deprecated since version 1.4.0: Append `.squeeze("columns")` to the call to `read_csv` to squeeze the data.

prefix [str, optional] Prefix to add to column numbers when no header, e.g. ‘X’ for X0, X1, ...

Deprecated since version 1.4.0: Use a list comprehension on the DataFrame’s columns after calling `read_csv`.

mangle_dupe_cols [bool, default True] Duplicate columns will be specified as ‘X’, ‘X.1’, ... ‘X.N’, rather than ‘X’...‘X’. Passing in False will cause data to be overwritten if there are duplicate names in the columns.

dtype [Type name or dict of column -> type, optional] Data type for data or columns. E.g. `{'a': np.float64, 'b': np.int32, 'c': 'Int64'}` Use `str` or `object` together with suitable `na_values` settings to preserve and not interpret `dtype`. If converters are specified, they will be applied INSTEAD of `dtype` conversion.

engine [{‘c’, ‘python’, ‘pyarrow’}], optional] Parser engine to use. The C and pyarrow engines are faster, while the python engine is currently more feature-complete. Multithreading is currently only supported by the pyarrow engine.

New in version 1.4.0: The “pyarrow” engine was added as an *experimental* engine, and some features are unsupported, or may not work correctly, with this engine.

converters [dict, optional] Dict of functions for converting values in certain columns. Keys can either be integers or column labels.

true_values [list, optional] Values to consider as True.

false_values [list, optional] Values to consider as False.

skipinitialspace [bool, default False] Skip spaces after delimiter.

skiprows [list-like, int or callable, optional] Line numbers to skip (0-indexed) or number of lines to skip (int) at the start of the file.

If callable, the callable function will be evaluated against the row indices, returning True if the row should be skipped and False otherwise. An example of a valid callable argument would be `lambda x: x in [0, 2]`.

skipfooter [int, default 0] Number of lines at bottom of file to skip (Unsupported with engine='c').

nrows [int, optional] Number of rows of file to read. Useful for reading pieces of large files.

na_values [scalar, str, list-like, or dict, optional] Additional strings to recognize as NA/NaN. If dict passed, specific per-column NA values. By default the following values are interpreted as NaN: ‘’, ‘#N/A’, ‘#N/A N/A’, ‘#NA’, ‘-1.#IND’, ‘-1.#QNAN’, ‘-NaN’, ‘-nan’, ‘1.#IND’, ‘1.#QNAN’, ‘<NA>’, ‘N/A’, ‘NA’, ‘NULL’, ‘NaN’, ‘n/a’, ‘nan’, ‘null’.

keep_default_na [bool, default True] Whether or not to include the default NaN values when parsing the data. Depending on whether *na_values* is passed in, the behavior is as follows:

- If *keep_default_na* is True, and *na_values* are specified, *na_values* is appended to the default NaN values used for parsing.
- If *keep_default_na* is True, and *na_values* are not specified, only the default NaN values are used for parsing.
- If *keep_default_na* is False, and *na_values* are specified, only the NaN values specified *na_values* are used for parsing.
- If *keep_default_na* is False, and *na_values* are not specified, no strings will be parsed as NaN.

Note that if *na_filter* is passed in as False, the *keep_default_na* and *na_values* parameters will be ignored.

na_filter [bool, default True] Detect missing value markers (empty strings and the value of *na_values*). In data without any NAs, passing *na_filter*=False can improve the performance of reading a large file.

verbose [bool, default False] Indicate number of NA values placed in non-numeric columns.

skip_blank_lines [bool, default True] If True, skip over blank lines rather than interpreting as NaN values.

parse_dates [bool or list of int or names or list of lists or dict, default False] The behavior is as follows:

- boolean. If True -> try parsing the index.
- list of int or names. e.g. If [1, 2, 3] -> try parsing columns 1, 2, 3 each as a separate date column.
- list of lists. e.g. If [[1, 3]] -> combine columns 1 and 3 and parse as a single date column.
- dict, e.g. {‘foo’ : [1, 3]} -> parse columns 1, 3 as date and call result ‘foo’

If a column or index cannot be represented as an array of datetimes, say because of an unparsable value or a mixture of timezones, the column or index will be returned unaltered as an object data type. For non-standard datetime parsing, use `pd.to_datetime` after `pd.read_csv`. To parse an index or column with a mixture of timezones, specify `date_parser` to be a partially-applied `pandas.to_datetime()` with `utc=True`. See [Parsing a CSV with mixed timezones](#) for more.

Note: A fast-path exists for iso8601-formatted dates.

infer_datetime_format [bool, default False] If True and *parse_dates* is enabled, pandas will attempt to infer the format of the datetime strings in the columns, and if it can be inferred,

switch to a faster method of parsing them. In some cases this can increase the parsing speed by 5-10x.

keep_date_col [bool, default False] If True and *parse_dates* specifies combining multiple columns then keep the original columns.

date_parser [function, optional] Function to use for converting a sequence of string columns to an array of datetime instances. The default uses `dateutil.parser.parser` to do the conversion. Pandas will try to call `date_parser` in three different ways, advancing to the next if an exception occurs: 1) Pass one or more arrays (as defined by *parse_dates*) as arguments; 2) concatenate (row-wise) the string values from the columns defined by *parse_dates* into a single array and pass that; and 3) call `date_parser` once for each row using one or more strings (corresponding to the columns defined by *parse_dates*) as arguments.

dayfirst [bool, default False] DD/MM format dates, international and European format.

cache_dates [bool, default True] If True, use a cache of unique, converted dates to apply the datetime conversion. May produce significant speed-up when parsing duplicate date strings, especially ones with timezone offsets.

New in version 0.25.0.

iterator [bool, default False] Return `TextFileReader` object for iteration or getting chunks with `get_chunk()`.

Changed in version 1.2: `TextFileReader` is a context manager.

chunksize [int, optional] Return `TextFileReader` object for iteration. See the [IO Tools](#) docs for more information on `iterator` and `chunksize`.

Changed in version 1.2: `TextFileReader` is a context manager.

compression [str or dict, default ‘infer’] For on-the-fly decompression of on-disk data. If ‘infer’ and ‘%s’ is path-like, then detect compression from the following extensions: ‘.gz’, ‘.bz2’, ‘.zip’, ‘.xz’, or ‘.zst’ (otherwise no compression). If using ‘zip’, the ZIP file must contain only one data file to be read in. Set to None for no decompression. Can also be a dict with key ‘method’ set to one of {'zip', 'gzip', 'bz2', 'zstd'} and other key-value pairs are forwarded to `zipfile.ZipFile`, `gzip.GzipFile`, `bz2.BZ2File`, or `zstandard.ZstdDecompressor`, respectively. As an example, the following could be passed for Zstandard decompression using a custom compression dictionary: `compression={'method': 'zstd', 'dict_data': my_compression_dict}`.

Changed in version 1.4.0: Zstandard support.

thousands [str, optional] Thousands separator.

decimal [str, default ‘.’] Character to recognize as decimal point (e.g. use ‘,’ for European data).

lineterminator [str (length 1), optional] Character to break file into lines. Only valid with C parser.

quotechar [str (length 1), optional] The character used to denote the start and end of a quoted item. Quoted items can include the delimiter and it will be ignored.

quoting [int or `csv.QUOTE_*` instance, default 0] Control field quoting behavior per `csv.QUOTE_*` constants. Use one of QUOTE_MINIMAL (0), QUOTE_ALL (1), QUOTE_NONNUMERIC (2) or QUOTE_NONE (3).

doublequote [bool, default True] When quotechar is specified and quoting is not QUOTE_NONE, indicate whether or not to interpret two consecutive quotechar elements INSIDE a field as a single quotechar element.

escapechar [str (length 1), optional] One-character string used to escape other characters.

comment [str, optional] Indicates remainder of line should not be parsed. If found at the beginning of a line, the line will be ignored altogether. This parameter must be a single character. Like empty lines (as long as `skip_blank_lines=True`), fully commented lines are ignored by the parameter `header` but not by `skiprows`. For example, if `comment='#'`, parsing `#empty\na,b,c\n1,2,3` with `header=0` will result in ‘a,b,c’ being treated as the header.

encoding [str, optional] Encoding to use for UTF when reading/writing (ex. ‘utf-8’). [List of Python standard encodings](#).

Changed in version 1.2: When `encoding` is `None`, `errors="replace"` is passed to `open()`. Otherwise, `errors="strict"` is passed to `open()`. This behavior was previously only the case for `engine="python"`.

Changed in version 1.3.0: `encoding_errors` is a new argument. `encoding` has no longer an influence on how encoding errors are handled.

encoding_errors [str, optional, default “strict”] How encoding errors are treated. [List of possible values](#).

New in version 1.3.0.

dialect [str or csv.Dialect, optional] If provided, this parameter will override values (default or not) for the following parameters: `delimiter`, `doublequote`, `escapechar`, `skipinitialspace`, `quotecchar`, and `quoting`. If it is necessary to override values, a `ParserWarning` will be issued. See `csv.Dialect` documentation for more details.

error_bad_lines [bool, optional, default None] Lines with too many fields (e.g. a csv line with too many commas) will by default cause an exception to be raised, and no DataFrame will be returned. If False, then these “bad lines” will be dropped from the DataFrame that is returned.

Deprecated since version 1.3.0: The `on_bad_lines` parameter should be used instead to specify behavior upon encountering a bad line instead.

warn_bad_lines [bool, optional, default None] If `error_bad_lines` is False, and `warn_bad_lines` is True, a warning for each “bad line” will be output.

Deprecated since version 1.3.0: The `on_bad_lines` parameter should be used instead to specify behavior upon encountering a bad line instead.

on_bad_lines [{‘error’, ‘warn’, ‘skip’} or callable, default ‘error’] Specifies what to do upon encountering a bad line (a line with too many fields). Allowed values are :

- ‘error’, raise an Exception when a bad line is encountered.
- ‘warn’, raise a warning when a bad line is encountered and skip that line.
- ‘skip’, skip bad lines without raising or warning when they are encountered.

New in version 1.3.0:

- callable, function with signature `(bad_line: list[str]) -> list[str] | None` that will process a single bad line. `bad_line` is a list of strings split by the `sep`. If the function returns `None`, the bad line will be ignored. If the function returns a new list of strings with more elements than expected, a `ParserWarning` will be emitted while dropping extra elements. Only supported when `engine="python"`

New in version 1.4.0.

delim_whitespace [bool, default False] Specifies whether or not whitespace (e.g. ‘ ’ or ‘ ’) will be used as the `sep`. Equivalent to setting `sep='\\s+'`. If this option is set to True, nothing should be passed in for the `delimiter` parameter.

low_memory [bool, default True] Internally process the file in chunks, resulting in lower memory use while parsing, but possibly mixed type inference. To ensure no mixed types either set False, or specify the type with the *dtype* parameter. Note that the entire file is read into a single DataFrame regardless, use the *chunksize* or *iterator* parameter to return the data in chunks. (Only valid with C parser).

memory_map [bool, default False] If a filepath is provided for *filepath_or_buffer*, map the file object directly onto memory and access the data directly from there. Using this option can improve performance because there is no longer any I/O overhead.

float_precision [str, optional] Specifies which converter the C engine should use for floating-point values. The options are `None` or ‘high’ for the ordinary converter, ‘legacy’ for the original lower precision pandas converter, and ‘round_trip’ for the round-trip converter.

Changed in version 1.2.

storage_options [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to `urllib` as header options. For other URLs (e.g. starting with “`s3://`”, and “`gcs://`”) the key-value pairs are forwarded to `fsspec`. Please see `fsspec` and `urllib` for more details.

New in version 1.2.

Returns

DataFrame or TextParser A comma-separated values (csv) file is returned as two-dimensional data structure with labeled axes.

See also:

[DataFrame.to_csv](#) Write DataFrame to a comma-separated values (csv) file.

[read_csv](#) Read a comma-separated values (csv) file into DataFrame.

[read_fwf](#) Read a table of fixed-width formatted lines into DataFrame.

Examples

```
>>> pd.read_csv('data.csv')
```

pandas.DataFrame.to_csv

`DataFrame.to_csv(path_or_buf=None, sep=',', na_rep=' ', float_format=None, columns=None, header=True, index=True, index_label=None, mode='w', encoding=None, compression='infer', quoting=None, quotechar='"', line_terminator=None, chunksize=None, date_format=None, doublequote=True, escapechar=None, decimal=',', errors='strict', storage_options=None)`

Write object to a comma-separated values (csv) file.

Parameters

path_or_buf [str, path object, file-like object, or None, default None] String, path object (implementing `os.PathLike[str]`), or file-like object implementing a `write()` function. If `None`, the result is returned as a string. If a non-binary file object is passed, it should be opened with `newline=`”, disabling universal newlines. If a binary file object is passed, `mode` might need to contain a ‘`b`’.

Changed in version 1.2.0: Support for binary file objects was introduced.

sep [str, default ','] String of length 1. Field delimiter for the output file.

na_rep [str, default ''] Missing data representation.

float_format [str, default None] Format string for floating point numbers.

columns [sequence, optional] Columns to write.

header [bool or list of str, default True] Write out the column names. If a list of strings is given it is assumed to be aliases for the column names.

index [bool, default True] Write row names (index).

index_label [str or sequence, or False, default None] Column label for index column(s) if desired. If None is given, and *header* and *index* are True, then the index names are used. A sequence should be given if the object uses MultiIndex. If False do not print fields for index names. Use *index_label*=False for easier importing in R.

mode [str] Python write mode, default 'w'.

encoding [str, optional] A string representing the encoding to use in the output file, defaults to 'utf-8'. *encoding* is not supported if *path_or_buf* is a non-binary file object.

compression [str or dict, default 'infer'] For on-the-fly compression of the output data. If 'infer' and '%os' path-like, then detect compression from the following extensions: '.gz', '.bz2', '.zip', '.xz', or '.zst' (otherwise no compression). Set to None for no compression. Can also be a dict with key 'method' set to one of {'zip', 'gzip', 'bz2', 'zstd'} and other key-value pairs are forwarded to `zipfile.ZipFile`, `gzip.GzipFile`, `bz2.BZ2File`, or `zstandard.ZstdDecompressor`, respectively. As an example, the following could be passed for faster compression and to create a reproducible gzip archive: `compression={'method': 'gzip', 'compresslevel': 1, 'mtime': 1}`.

Changed in version 1.0.0: May now be a dict with key 'method' as compression mode and other entries as additional compression options if compression mode is 'zip'.

Changed in version 1.1.0: Passing compression options as keys in dict is supported for compression modes 'gzip', 'bz2', 'zstd', and 'zip'.

Changed in version 1.2.0: Compression is supported for binary file objects.

Changed in version 1.2.0: Previous versions forwarded dict entries for 'gzip' to `gzip.open` instead of `gzip.GzipFile` which prevented setting *mtime*.

quoting [optional constant from csv module] Defaults to `csv.QUOTE_MINIMAL`. If you have set a *float_format* then floats are converted to strings and thus `csv.QUOTE_NONNUMERIC` will treat them as non-numeric.

quotechar [str, default ""] String of length 1. Character used to quote fields.

line_terminator [str, optional] The newline character or character sequence to use in the output file. Defaults to `os.linesep`, which depends on the OS in which this method is called ('\n' for linux, '\r\n' for Windows, i.e.).

chunksize [int or None] Rows to write at a time.

date_format [str, default None] Format string for datetime objects.

doublequote [bool, default True] Control quoting of *quotechar* inside a field.

escapechar [str, default None] String of length 1. Character used to escape *sep* and *quotechar* when appropriate.

decimal [str, default '.'] Character recognized as decimal separator. E.g. use ',' for European data.

errors [str, default ‘strict’] Specifies how encoding and decoding errors are to be handled. See the errors argument for `open()` for a full list of options.

New in version 1.1.0.

storage_options [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to `urllib` as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to `fsspec`. Please see `fsspec` and `urllib` for more details.

New in version 1.2.0.

Returns

None or str If `path_or_buf` is `None`, returns the resulting csv format as a string. Otherwise returns `None`.

See also:

`read_csv` Load a CSV file into a DataFrame.

`to_excel` Write DataFrame to an Excel file.

Examples

```
>>> df = pd.DataFrame({'name': ['Raphael', 'Donatello'],
...                     'mask': ['red', 'purple'],
...                     'weapon': ['sai', 'bo staff']})
>>> df.to_csv(index=False)
'name,mask,weapon\nRaphael,red,sai\nDonatello,purple,bo staff\n'
```

Create ‘out.zip’ containing ‘out.csv’

```
>>> compression_opts = dict(method='zip',
...                           archive_name='out.csv')
>>> df.to_csv('out.zip', index=False,
...            compression=compression_opts)
```

To write a csv file to a new folder or nested folder you will first need to create it using either Pathlib or os:

```
>>> from pathlib import Path
>>> filepath = Path('folder/subfolder/out.csv')
>>> filepath.parent.mkdir(parents=True, exist_ok=True)
>>> df.to_csv(filepath)
```

```
>>> import os
>>> os.makedirs('folder/subfolder', exist_ok=True)
>>> df.to_csv('folder/subfolder/out.csv')
```

`pandas.read_fwf`

`pandas.read_fwf(filepath_or_buffer, colspecs='infer', widths=None, infer_nrows=100, **kwds)`

Read a table of fixed-width formatted lines into DataFrame.

Also supports optionally iterating or breaking of the file into chunks.

Additional help can be found in the [online docs for IO Tools](#).

Parameters

filepath_or_buffer [str, path object, or file-like object] String, path object (implementing `os.PathLike[str]`), or file-like object implementing a text `read()` function. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. A local file could be: `file:///localhost/path/to/table.csv`.

colspecs [list of tuple (int, int) or ‘infer’. optional] A list of tuples giving the extents of the fixed-width fields of each line as half-open intervals (i.e., [from, to[). String value ‘infer’ can be used to instruct the parser to try detecting the column specifications from the first 100 rows of the data which are not being skipped via `skiprows` (default=‘infer’).

widths [list of int, optional] A list of field widths which can be used instead of ‘colspecs’ if the intervals are contiguous.

infer_nrows [int, default 100] The number of rows to consider when letting the parser determine the `colspecs`.

****kwds** [optional] Optional keyword arguments can be passed to `TextFileReader`.

Returns

DataFrame or TextFileReader A comma-separated values (csv) file is returned as two-dimensional data structure with labeled axes.

See also:

[`DataFrame.to_csv`](#) Write DataFrame to a comma-separated values (csv) file.

[`read_csv`](#) Read a comma-separated values (csv) file into DataFrame.

Examples

```
>>> pd.read_fwf('data.csv')
```

3.1.3 Clipboard

<code>read_clipboard([sep])</code>	Read text from clipboard and pass to <code>read_csv</code> .
------------------------------------	--

<code>DataFrame.to_clipboard([excel, sep])</code>	Copy object to the system clipboard.
---	--------------------------------------

pandas.read_clipboard

`pandas.read_clipboard(sep='\\s+', **kwargs)`
Read text from clipboard and pass to read_csv.

Parameters

- sep** [str, default ‘s+’] A string or regex delimiter. The default of ‘s+’ denotes one or more whitespace characters.
- **kwargs** See read_csv for the full argument list.

Returns

DataFrame A parsed DataFrame object.

pandas.DataFrame.to_clipboard

`DataFrame.to_clipboard(excel=True, sep=None, **kwargs)`
Copy object to the system clipboard.

Write a text representation of object to the system clipboard. This can be pasted into Excel, for example.

Parameters

- excel** [bool, default True] Produce output in a csv format for easy pasting into excel.
 - True, use the provided separator for csv pasting.
 - False, write a string representation of the object to the clipboard.
- sep** [str, default '\t'] Field delimiter.
- **kwargs** These parameters will be passed to DataFrame.to_csv.

See also:

[**DataFrame.to_csv**](#) Write a DataFrame to a comma-separated values (csv) file.

[**read_clipboard**](#) Read text from clipboard and pass to read_csv.

Notes

Requirements for your platform.

- Linux : *xclip*, or *xsel* (with *PyQt4* modules)
- Windows : none
- macOS : none

Examples

Copy the contents of a DataFrame to the clipboard.

```
>>> df = pd.DataFrame([[1, 2, 3], [4, 5, 6]], columns=['A', 'B', 'C'])
```

```
>>> df.to_clipboard(sep=',')
... # Wrote the following to the system clipboard:
... # ,A,B,C
... # 0,1,2,3
... # 1,4,5,6
```

We can omit the index by passing the keyword `index` and setting it to false.

```
>>> df.to_clipboard(sep=',', index=False)
... # Wrote the following to the system clipboard:
... # A,B,C
... # 1,2,3
... # 4,5,6
```

3.1.4 Excel

<code>read_excel(io[, sheet_name, header, names, ...])</code>	Read an Excel file into a pandas DataFrame.
---	---

<code>DataFrame.to_excel(excel_writer[, ...])</code>	Write object to an Excel sheet.
--	---------------------------------

<code>ExcelFile.parse([sheet_name, header, names, ...])</code>	Parse specified sheet(s) into a DataFrame.
--	--

pandas.read_excel

```
pandas.read_excel(io, sheet_name=0, header=0, names=None, index_col=None, usecols=None, squeeze=None,
                  dtype=None, engine=None, converters=None, true_values=None, false_values=None,
                  skiprows=None, nrows=None, na_values=None, keep_default_na=True, na_filter=True,
                  verbose=False, parse_dates=False, date_parser=None, thousands=None, decimal=',',
                  comment=None, skipfooter=0, convert_float=None, mangle_dupe_cols=True,
                  storage_options=None)
```

Read an Excel file into a pandas DataFrame.

Supports `xls`, `xlsx`, `xlsm`, `xlsb`, `odf`, `ods` and `odt` file extensions read from a local filesystem or URL. Supports an option to read a single sheet or a list of sheets.

Parameters

io [str, bytes, ExcelFile, xlrd.Book, path object, or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. A local file could be: `file://localhost/path/to/table.xls`.

If you want to pass in a path object, pandas accepts any `os.PathLike`.

By file-like object, we refer to objects with a `read()` method, such as a file handle (e.g. via builtin `open` function) or `StringIO`.

sheet_name [str, int, list, or None, default 0] Strings are used for sheet names. Integers are used in zero-indexed sheet positions (chart sheets do not count as a sheet position). Lists of strings/integers are used to request multiple sheets. Specify None to get all worksheets.

Available cases:

- Defaults to 0: 1st sheet as a *DataFrame*
- 1: 2nd sheet as a *DataFrame*
- "Sheet1": Load sheet with name "Sheet1"
- [0, 1, "Sheet5"] : Load first, second and sheet named "Sheet5" as a dict of *DataFrame*
- None: All worksheets.

header [int, list of int, default 0] Row (0-indexed) to use for the column labels of the parsed DataFrame. If a list of integers is passed those row positions will be combined into a MultiIndex. Use None if there is no header.

names [array-like, default None] List of column names to use. If file contains no header row, then you should explicitly pass header=None.

index_col [int, list of int, default None] Column (0-indexed) to use as the row labels of the DataFrame. Pass None if there is no such column. If a list is passed, those columns will be combined into a MultiIndex. If a subset of data is selected with usecols, index_col is based on the subset.

usecols [int, str, list-like, or callable default None]

- If None, then parse all columns.
- If str, then indicates comma separated list of Excel column letters and column ranges (e.g. "A:E" or "A,C,E:F"). Ranges are inclusive of both sides.
- If list of int, then indicates list of column numbers to be parsed.
- If list of string, then indicates list of column names to be parsed.
- If callable, then evaluate each column name against it and parse the column if the callable returns True.

Returns a subset of the columns according to behavior above.

squeeze [bool, default False] If the parsed data only contains one column then return a Series.

Deprecated since version 1.4.0: Append .squeeze("columns") to the call to read_excel to squeeze the data.

dtype [Type name or dict of column -> type, default None] Data type for data or columns. E.g. {'a': np.float64, 'b': np.int32} Use *object* to preserve data as stored in Excel and not interpret dtype. If converters are specified, they will be applied INSTEAD of dtype conversion.

engine [str, default None] If io is not a buffer or path, this must be set to identify io. Supported engines: "xlrd", "openpyxl", "odf", "pyxlsb". Engine compatibility :

- "xlrd" supports old-style Excel files (.xls).
- "openpyxl" supports newer Excel file formats.
- "odf" supports OpenDocument file formats (.odf, .ods, .odt).
- "pyxlsb" supports Binary Excel files.

Changed in version 1.2.0: The engine xlrd now only supports old-style .xls files. When engine=None, the following logic will be used to determine the engine:

- If path_or_buffer is an OpenDocument format (.odf, .ods, .odt), then odf will be used.
- Otherwise if path_or_buffer is an xls format, xlrd will be used.

- Otherwise if `path_or_buffer` is in `xlsb` format, `pyxlsb` will be used.

New in version 1.3.0.

- Otherwise `openpyxl` will be used.

Changed in version 1.3.0.

converters [dict, default None] Dict of functions for converting values in certain columns. Keys can either be integers or column labels, values are functions that take one input argument, the Excel cell content, and return the transformed content.

true_values [list, default None] Values to consider as True.

false_values [list, default None] Values to consider as False.

skiprows [list-like, int, or callable, optional] Line numbers to skip (0-indexed) or number of lines to skip (int) at the start of the file. If callable, the callable function will be evaluated against the row indices, returning True if the row should be skipped and False otherwise. An example of a valid callable argument would be `lambda x: x in [0, 2]`.

nrows [int, default None] Number of rows to parse.

na_values [scalar, str, list-like, or dict, default None] Additional strings to recognize as NA/NaN.

If dict passed, specific per-column NA values. By default the following values are interpreted as NaN: '', '#N/A', '#N/A N/A', '#NA', '-1.#IND', '-1.#QNAN', '-NaN', '-nan', '1.#IND', '1.#QNAN', '<NA>', 'N/A', 'NA', 'NULL', 'NaN', 'n/a', 'nan', 'null'.

keep_default_na [bool, default True] Whether or not to include the default NaN values when parsing the data. Depending on whether `na_values` is passed in, the behavior is as follows:

- If `keep_default_na` is True, and `na_values` are specified, `na_values` is appended to the default NaN values used for parsing.
- If `keep_default_na` is True, and `na_values` are not specified, only the default NaN values are used for parsing.
- If `keep_default_na` is False, and `na_values` are specified, only the NaN values specified `na_values` are used for parsing.
- If `keep_default_na` is False, and `na_values` are not specified, no strings will be parsed as NaN.

Note that if `na_filter` is passed in as False, the `keep_default_na` and `na_values` parameters will be ignored.

na_filter [bool, default True] Detect missing value markers (empty strings and the value of `na_values`). In data without any NAs, passing `na_filter=False` can improve the performance of reading a large file.

verbose [bool, default False] Indicate number of NA values placed in non-numeric columns.

parse_dates [bool, list-like, or dict, default False] The behavior is as follows:

- bool. If True -> try parsing the index.
- list of int or names. e.g. If [1, 2, 3] -> try parsing columns 1, 2, 3 each as a separate date column.
- list of lists. e.g. If [[1, 3]] -> combine columns 1 and 3 and parse as a single date column.
- dict, e.g. {'foo' : [1, 3]} -> parse columns 1, 3 as date and call result 'foo'

If a column or index contains an unparsable date, the entire column or index will be returned unaltered as an object data type. If you don't want to parse some cells as date just change

their type in Excel to “Text”. For non-standard datetime parsing, use `pd.to_datetime` after `pd.read_excel`.

Note: A fast-path exists for iso8601-formatted dates.

date_parser [function, optional] Function to use for converting a sequence of string columns to an array of datetime instances. The default uses `dateutil.parser.parser` to do the conversion. Pandas will try to call `date_parser` in three different ways, advancing to the next if an exception occurs: 1) Pass one or more arrays (as defined by `parse_dates`) as arguments; 2) concatenate (row-wise) the string values from the columns defined by `parse_dates` into a single array and pass that; and 3) call `date_parser` once for each row using one or more strings (corresponding to the columns defined by `parse_dates`) as arguments.

thousands [str, default None] Thousands separator for parsing string columns to numeric. Note that this parameter is only necessary for columns stored as TEXT in Excel, any numeric columns will automatically be parsed, regardless of display format.

decimal [str, default ‘.’] Character to recognize as decimal point for parsing string columns to numeric. Note that this parameter is only necessary for columns stored as TEXT in Excel, any numeric columns will automatically be parsed, regardless of display format.(e.g. use ‘,’ for European data).

New in version 1.4.0.

comment [str, default None] Comments out remainder of line. Pass a character or characters to this argument to indicate comments in the input file. Any data between the comment string and the end of the current line is ignored.

skipfooter [int, default 0] Rows at the end to skip (0-indexed).

convert_float [bool, default True] Convert integral floats to int (i.e., 1.0 → 1). If False, all numeric data will be read in as floats: Excel stores all numbers as floats internally.

Deprecated since version 1.3.0: `convert_float` will be removed in a future version

mangle_dupe_cols [bool, default True] Duplicate columns will be specified as ‘X’, ‘X.1’, … ‘X.N’, rather than ‘X’…‘X’. Passing in False will cause data to be overwritten if there are duplicate names in the columns.

storage_options [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc., if using a URL that will be parsed by `fsspec`, e.g., starting “`s3://`”, “`gcs://`”. An error will be raised if providing this argument with a local path or a file-like buffer. See the `fsspec` and backend storage implementation docs for the set of allowed keys and values.

New in version 1.2.0.

Returns

DataFrame or dict of DataFrames DataFrame from the passed in Excel file. See notes in `sheet_name` argument for more information on when a dict of DataFrames is returned.

See also:

`DataFrame.to_excel` Write DataFrame to an Excel file.

`DataFrame.to_csv` Write DataFrame to a comma-separated values (csv) file.

`read_csv` Read a comma-separated values (csv) file into DataFrame.

`read_fwf` Read a table of fixed-width formatted lines into DataFrame.

Examples

The file can be read using the file name as string or an open file object:

```
>>> pd.read_excel('tmp.xlsx', index_col=0)
      Name  Value
0  string1     1
1  string2     2
2 #Comment     3
```

```
>>> pd.read_excel(open('tmp.xlsx', 'rb'),
...                  sheet_name='Sheet3')
   Unnamed: 0      Name  Value
0            0  string1     1
1            1  string2     2
2            2 #Comment     3
```

Index and header can be specified via the *index_col* and *header* arguments

```
>>> pd.read_excel('tmp.xlsx', index_col=None, header=None)
      0      1      2
0  NaN      Name  Value
1  0.0  string1     1
2  1.0  string2     2
3  2.0 #Comment     3
```

Column types are inferred but can be explicitly specified

```
>>> pd.read_excel('tmp.xlsx', index_col=0,
...                  dtype={'Name': str, 'Value': float})
      Name  Value
0  string1    1.0
1  string2    2.0
2 #Comment    3.0
```

True, False, and NA values, and thousands separators have defaults, but can be explicitly specified, too. Supply the values you would like as strings or lists of strings!

```
>>> pd.read_excel('tmp.xlsx', index_col=0,
...                  na_values=['string1', 'string2'])
      Name  Value
0    NaN     1
1    NaN     2
2 #Comment     3
```

Comment lines in the excel input file can be skipped using the *comment* kwarg

```
>>> pd.read_excel('tmp.xlsx', index_col=0, comment='#')
      Name  Value
0  string1    1.0
1  string2    2.0
2    None    NaN
```

pandas.DataFrame.to_excel

```
DataFrame.to_excel(excel_writer, sheet_name='Sheet1', na_rep='', float_format=None, columns=None,
                  header=True, index=True, index_label=None, startrow=0, startcol=0, engine=None,
                  merge_cells=True, encoding=None, inf_rep='inf', verbose=True, freeze_panes=None,
                  storage_options=None)
```

Write object to an Excel sheet.

To write a single object to an Excel .xlsx file it is only necessary to specify a target file name. To write to multiple sheets it is necessary to create an *ExcelWriter* object with a target file name, and specify a sheet in the file to write to.

Multiple sheets may be written to by specifying unique *sheet_name*. With all data written to the file it is necessary to save the changes. Note that creating an *ExcelWriter* object with a file name that already exists will result in the contents of the existing file being erased.

Parameters

excel_writer [path-like, file-like, or ExcelWriter object] File path or existing ExcelWriter.

sheet_name [str, default ‘Sheet1’] Name of sheet which will contain DataFrame.

na_rep [str, default ‘’] Missing data representation.

float_format [str, optional] Format string for floating point numbers. For example `float_format=".2f"` will format 0.1234 to 0.12.

columns [sequence or list of str, optional] Columns to write.

header [bool or list of str, default True] Write out the column names. If a list of string is given it is assumed to be aliases for the column names.

index [bool, default True] Write row names (index).

index_label [str or sequence, optional] Column label for index column(s) if desired. If not specified, and *header* and *index* are True, then the index names are used. A sequence should be given if the DataFrame uses MultiIndex.

startrow [int, default 0] Upper left cell row to dump data frame.

startcol [int, default 0] Upper left cell column to dump data frame.

engine [str, optional] Write engine to use, ‘openpyxl’ or ‘xlsxwriter’. You can also set this via the options `io.excel.xlsx.writer`, `io.excel.xls.writer`, and `io.excel.xlsm.writer`.

Deprecated since version 1.2.0: As the `xlwt` package is no longer maintained, the `xlwt` engine will be removed in a future version of pandas.

merge_cells [bool, default True] Write MultiIndex and Hierarchical Rows as merged cells.

encoding [str, optional] Encoding of the resulting excel file. Only necessary for xlwt, other writers support unicode natively.

inf_rep [str, default ‘inf’] Representation for infinity (there is no native representation for infinity in Excel).

verbose [bool, default True] Display more information in the error logs.

freeze_panes [tuple of int (length 2), optional] Specifies the one-based bottommost row and rightmost column that is to be frozen.

storage_options [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are

forwarded to `urllib` as header options. For other URLs (e.g. starting with “`s3://`”, and “`gcs://`”) the key-value pairs are forwarded to `fsspec`. Please see `fsspec` and `urllib` for more details.

New in version 1.2.0.

See also:

[`to_csv`](#) Write DataFrame to a comma-separated values (csv) file.

[`ExcelWriter`](#) Class for writing DataFrame objects into excel sheets.

[`read_excel`](#) Read an Excel file into a pandas DataFrame.

[`read_csv`](#) Read a comma-separated values (csv) file into DataFrame.

Notes

For compatibility with `to_csv()`, `to_excel` serializes lists and dicts to strings before writing.

Once a workbook has been saved it is not possible to write further data without rewriting the whole workbook.

Examples

Create, write to and save a workbook:

```
>>> df1 = pd.DataFrame([[{'a': 'b'}, {'c': 'd'}],
...                     index=['row 1', 'row 2'],
...                     columns=['col 1', 'col 2'])
>>> df1.to_excel("output.xlsx")
```

To specify the sheet name:

```
>>> df1.to_excel("output.xlsx",
...                 sheet_name='Sheet_name_1')
```

If you wish to write to more than one sheet in the workbook, it is necessary to specify an `ExcelWriter` object:

```
>>> df2 = df1.copy()
>>> with pd.ExcelWriter('output.xlsx') as writer:
...     df1.to_excel(writer, sheet_name='Sheet_name_1')
...     df2.to_excel(writer, sheet_name='Sheet_name_2')
```

`ExcelWriter` can also be used to append to an existing Excel file:

```
>>> with pd.ExcelWriter('output.xlsx',
...                      mode='a') as writer:
...     df.to_excel(writer, sheet_name='Sheet_name_3')
```

To set the library that is used to write the Excel file, you can pass the `engine` keyword (the default engine is automatically chosen depending on the file extension):

```
>>> df1.to_excel('output1.xlsx', engine='xlsxwriter')
```

pandas.ExcelFile.parse

```
ExcelFile.parse(sheet_name=0, header=0, names=None, index_col=None, usecols=None, squeeze=None,
               converters=None, true_values=None, false_values=None, skiprows=None, nrows=None,
               na_values=None, parse_dates=False, date_parser=None, thousands=None, comment=None,
               skipfooter=0, convert_float=None, mangle_dupe_cols=True, **kwds)
```

Parse specified sheet(s) into a DataFrame.

Equivalent to read_excel(ExcelFile, ...) See the read_excel docstring for more info on accepted parameters.

Returns

DataFrame or dict of DataFrames DataFrame from the passed in Excel file.

<code>Styler.to_excel(excel_writer[, sheet_name, ...])</code>	Write Styler to an Excel sheet.
---	---------------------------------

pandas.io.formats.style.Styler.to_excel

```
Styler.to_excel(excel_writer, sheet_name='Sheet1', na_rep='', float_format=None, columns=None,
               header=True, index=True, index_label=None, startrow=0, startcol=0, engine=None,
               merge_cells=True, encoding=None, inf_rep='inf', verbose=True, freeze_panes=None)
```

Write Styler to an Excel sheet.

To write a single Styler to an Excel .xlsx file it is only necessary to specify a target file name. To write to multiple sheets it is necessary to create an *ExcelWriter* object with a target file name, and specify a sheet in the file to write to.

Multiple sheets may be written to by specifying unique *sheet_name*. With all data written to the file it is necessary to save the changes. Note that creating an *ExcelWriter* object with a file name that already exists will result in the contents of the existing file being erased.

Parameters

excel_writer [path-like, file-like, or ExcelWriter object] File path or existing ExcelWriter.

sheet_name [str, default ‘Sheet1’] Name of sheet which will contain DataFrame.

na_rep [str, default ‘’] Missing data representation.

float_format [str, optional] Format string for floating point numbers. For example `float_format=".2f"` will format 0.1234 to 0.12.

columns [sequence or list of str, optional] Columns to write.

header [bool or list of str, default True] Write out the column names. If a list of string is given it is assumed to be aliases for the column names.

index [bool, default True] Write row names (index).

index_label [str or sequence, optional] Column label for index column(s) if desired. If not specified, and *header* and *index* are True, then the index names are used. A sequence should be given if the DataFrame uses MultiIndex.

startrow [int, default 0] Upper left cell row to dump data frame.

startcol [int, default 0] Upper left cell column to dump data frame.

engine [str, optional] Write engine to use, ‘openpyxl’ or ‘xlsxwriter’. You can also set this via the options `io.excel.xlsx.writer`, `io.excel.xls.writer`, and `io.excel.xls.writer`.

Deprecated since version 1.2.0: As the `xlwt` package is no longer maintained, the `xlwt` engine will be removed in a future version of pandas.

merge_cells [bool, default True] Write MultiIndex and Hierarchical Rows as merged cells.

encoding [str, optional] Encoding of the resulting excel file. Only necessary for xlwt, other writers support unicode natively.

inf_rep [str, default ‘inf’] Representation for infinity (there is no native representation for infinity in Excel).

verbose [bool, default True] Display more information in the error logs.

freeze_panes [tuple of int (length 2), optional] Specifies the one-based bottommost row and rightmost column that is to be frozen.

storage_options [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to `urllib` as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to `fsspec`. Please see `fsspec` and `urllib` for more details.

New in version 1.2.0.

See also:

to_csv Write DataFrame to a comma-separated values (csv) file.

ExcelWriter Class for writing DataFrame objects into excel sheets.

read_excel Read an Excel file into a pandas DataFrame.

read_csv Read a comma-separated values (csv) file into DataFrame.

Notes

For compatibility with `to_csv()`, `to_excel` serializes lists and dicts to strings before writing.

Once a workbook has been saved it is not possible to write further data without rewriting the whole workbook.

Examples

Create, write to and save a workbook:

```
>>> df1 = pd.DataFrame([[ 'a', 'b'], [ 'c', 'd']],
...                      index=[ 'row 1', 'row 2'],
...                      columns=[ 'col 1', 'col 2'])
>>> df1.to_excel("output.xlsx")
```

To specify the sheet name:

```
>>> df1.to_excel("output.xlsx",
...                 sheet_name='Sheet_name_1')
```

If you wish to write to more than one sheet in the workbook, it is necessary to specify an `ExcelWriter` object:

```
>>> df2 = df1.copy()
>>> with pd.ExcelWriter('output.xlsx') as writer:
...     df1.to_excel(writer, sheet_name='Sheet_name_1')
...     df2.to_excel(writer, sheet_name='Sheet_name_2')
```

ExcelWriter can also be used to append to an existing Excel file:

```
>>> with pd.ExcelWriter('output.xlsx',
...                      mode='a') as writer:
...     df.to_excel(writer, sheet_name='Sheet_name_3')
```

To set the library that is used to write the Excel file, you can pass the *engine* keyword (the default engine is automatically chosen depending on the file extension):

```
>>> df1.to_excel('output1.xlsx', engine='xlsxwriter')
```

`ExcelWriter(path[, engine, date_format, ...])`

Class for writing DataFrame objects into excel sheets.

pandas.ExcelWriter

```
class pandas.ExcelWriter(path, engine=None, date_format=None, datetime_format=None, mode='w',
                         storage_options=None, if_sheet_exists=None, engine_kwargs=None, **kwargs)
```

Class for writing DataFrame objects into excel sheets.

Default is to use : * xlwt for xls * xlsxwriter for xlsx if xlsxwriter is installed otherwise openpyxl * odf for ods. See DataFrame.to_excel for typical usage.

The writer should be used as a context manager. Otherwise, call *close()* to save and close any opened file handles.

Parameters

path [str or typing.BinaryIO] Path to xls or xlsx or ods file.

engine [str(optional)] Engine to use for writing. If None, defaults to `io.excel.<extension>.writer`. NOTE: can only be passed as a keyword argument.

Deprecated since version 1.2.0: As the `xlwt` package is no longer maintained, the `xlwt` engine will be removed in a future version of pandas.

date_format [str, default None] Format string for dates written into Excel files (e.g. ‘YYYY-MM-DD’).

datetime_format [str, default None] Format string for datetime objects written into Excel files. (e.g. ‘YYYY-MM-DD HH:MM:SS’).

mode [{‘w’, ‘a’}, default ‘w’] File mode to use (write or append). Append does not work with fsspec URLs.

storage_options [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc., if using a URL that will be parsed by fsspec, e.g., starting “s3://”, “gcs://”.

New in version 1.2.0.

if_sheet_exists [{‘error’, ‘new’, ‘replace’, ‘overlay’}, default ‘error’] How to behave when trying to write to a sheet that already exists (append mode only).

- error: raise a ValueError.

- new: Create a new sheet, with a name determined by the engine.
- replace: Delete the contents of the sheet before writing to it.
- overlay: Write contents to the existing sheet without removing the old contents.

New in version 1.3.0.

Changed in version 1.4.0: Added `overlay` option

engine_kwds [dict, optional] Keyword arguments to be passed into the engine. These will be passed to the following functions of the respective engines:

- `xlsxwriter`: `xlsxwriter.Workbook(file, **engine_kwds)`
- `openpyxl` (write mode): `openpyxl.Workbook(**engine_kwds)`
- `openpyxl` (append mode): `openpyxl.load_workbook(file, **engine_kwds)`
- `odswriter`: `odf.opendocument.OpenDocumentSpreadsheet(**engine_kwds)`

New in version 1.3.0.

****kwargs** [dict, optional] Keyword arguments to be passed into the engine.

Deprecated since version 1.3.0: Use `engine_kwds` instead.

Notes

None of the methods and properties are considered public.

For compatibility with CSV writers, ExcelWriter serializes lists and dicts to strings before writing.

Examples

Default usage:

```
>>> df = pd.DataFrame([[ "ABC", "XYZ"]], columns=[ "Foo", "Bar"])
>>> with pd.ExcelWriter("path_to_file.xlsx") as writer:
...     df.to_excel(writer)
```

To write to separate sheets in a single file:

```
>>> df1 = pd.DataFrame([[ "AAA", "BBB"]], columns=[ "Spam", "Egg"])
>>> df2 = pd.DataFrame([[ "ABC", "XYZ"]], columns=[ "Foo", "Bar"])
>>> with pd.ExcelWriter("path_to_file.xlsx") as writer:
...     df1.to_excel(writer, sheet_name="Sheet1")
...     df2.to_excel(writer, sheet_name="Sheet2")
```

You can set the date format or datetime format:

```
>>> from datetime import date, datetime
>>> df = pd.DataFrame(
...     [
...         [date(2014, 1, 31), date(1999, 9, 24)],
...         [datetime(1998, 5, 26, 23, 33, 4), datetime(2014, 2, 28, 13, 5, 13)],
...     ],
...     index=[ "Date", "Datetime" ],
...     columns=[ "X", "Y" ],
```

(continues on next page)

(continued from previous page)

```

... )
>>> with pd.ExcelWriter(
...     "path_to_file.xlsx",
...     date_format="YYYY-MM-DD",
...     datetime_format="YYYY-MM-DD HH:MM:SS"
... ) as writer:
...     df.to_excel(writer)

```

You can also append to an existing Excel file:

```

>>> with pd.ExcelWriter("path_to_file.xlsx", mode="a", engine="openpyxl") as writer:
...     df.to_excel(writer, sheet_name="Sheet3")

```

Here, the `if_sheet_exists` parameter can be set to replace a sheet if it already exists:

```

>>> with ExcelWriter(
...     "path_to_file.xlsx",
...     mode="a",
...     engine="openpyxl",
...     if_sheet_exists="replace",
... ) as writer:
...     df.to_excel(writer, sheet_name="Sheet1")

```

You can also write multiple DataFrames to a single sheet. Note that the `if_sheet_exists` parameter needs to be set to `overlay`:

```

>>> with ExcelWriter("path_to_file.xlsx",
...     mode="a",
...     engine="openpyxl",
...     if_sheet_exists="overlay",
... ) as writer:
...     df1.to_excel(writer, sheet_name="Sheet1")
...     df2.to_excel(writer, sheet_name="Sheet1", startcol=3)

```

You can store Excel file in RAM:

```

>>> import io
>>> df = pd.DataFrame([["ABC", "XYZ"]], columns=["Foo", "Bar"])
>>> buffer = io.BytesIO()
>>> with pd.ExcelWriter(buffer) as writer:
...     df.to_excel(writer)

```

You can pack Excel file into zip archive:

```

>>> import zipfile
>>> df = pd.DataFrame([["ABC", "XYZ"]], columns=["Foo", "Bar"])
>>> with zipfile.ZipFile("path_to_file.zip", "w") as zf:
...     with zf.open("filename.xlsx", "w") as buffer:
...         with pd.ExcelWriter(buffer) as writer:
...             df.to_excel(writer)

```

You can specify additional arguments to the underlying engine:

```
>>> with pd.ExcelWriter(
...     "path_to_file.xlsx",
...     engine="xlsxwriter",
...     engine_kwargs={"options": {"nan_inf_to_errors": True}}
... ) as writer:
...     df.to_excel(writer)
```

In append mode, engine_kwargs are passed through to openpyxl's load_workbook:

```
>>> with pd.ExcelWriter(
...     "path_to_file.xlsx",
...     engine="openpyxl",
...     mode="a",
...     engine_kwargs={"keep_vba": True}
... ) as writer:
...     df.to_excel(writer, sheet_name="Sheet2")
```

Attributes

None	<input type="button" value=""/>
------	---------------------------------

Methods

None	<input type="button" value=""/>
------	---------------------------------

3.1.5 JSON

<code>read_json([path_or_buf, orient, typ, dtype, ...])</code>	Convert a JSON string to pandas object.
<code>json_normalize(data[, record_path, meta, ...])</code>	Normalize semi-structured JSON data into a flat table.
<code>DataFrame.to_json([path_or_buf, orient, ...])</code>	Convert the object to a JSON string.

pandas.read_json

```
pandas.read_json(path_or_buf=None, orient=None, typ='frame', dtype=None, convert_axes=None,
                  convert_dates=True, keep_default_dates=True, numpy=False, precise_float=False,
                  date_unit=None, encoding=None, encoding_errors='strict', lines=False, chunksize=None,
                  compression='infer', nrows=None, storage_options=None)
```

Convert a JSON string to pandas object.

Parameters

path_or_buf [a valid JSON str, path object or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. A local file could be: `file://localhost/path/to/table.json`.

If you want to pass in a path object, pandas accepts any `os.PathLike`.

By file-like object, we refer to objects with a `read()` method, such as a file handle (e.g. via `builtin open` function) or `StringIO`.

orient [str] Indication of expected JSON string format. Compatible JSON strings can be produced by `to_json()` with a corresponding orient value. The set of possible orient values is:

- 'split' : dict like {index -> [index], columns -> [columns], data -> [values]}
- 'records' : list like [{column -> value}, ... , {column -> value}]
- 'index' : dict like {index -> {column -> value}}
- 'columns' : dict like {column -> {index -> value}}
- 'values' : just the values array

The allowed and default values depend on the value of the `typ` parameter.

- when `typ == 'series'`,
 - allowed orient values are {'split', 'records', 'index'}
 - default is 'index'
 - The Series index must be unique for orient 'index'.
- when `typ == 'frame'`,
 - allowed orient values are {'split', 'records', 'index', 'columns', 'values', 'table'}
 - default is 'columns'
 - The DataFrame index must be unique for orient 'index' and 'columns'.
 - The DataFrame columns must be unique for orient 'index', 'columns', and 'records'.

typ [{‘frame’, ‘series’}, default ‘frame’] The type of object to recover.

dtype [bool or dict, default None] If True, infer dtypes; if a dict of column to dtype, then use those; if False, then don’t infer dtypes at all, applies only to the data.

For all `orient` values except 'table', default is True.

Changed in version 0.25.0: Not applicable for `orient='table'`.

convert_axes [bool, default None] Try to convert the axes to the proper dtypes.

For all `orient` values except 'table', default is True.

Changed in version 0.25.0: Not applicable for `orient='table'`.

convert_dates [bool or list of str, default True] If True then default datelike columns may be converted (depending on `keep_default_dates`). If False, no dates will be converted. If a list of column names, then those columns will be converted and default datelike columns may also be converted (depending on `keep_default_dates`).

keep_default_dates [bool, default True] If parsing dates (`convert_dates` is not False), then try to parse the default datelike columns. A column label is datelike if

- it ends with '_at',
- it ends with '_time',
- it begins with 'timestamp',

- it is 'modified', or
- it is 'date'.

numpy [bool, default False] Direct decoding to numpy arrays. Supports numeric data only, but non-numeric column and index labels are supported. Note also that the JSON ordering MUST be the same for each term if numpy=True.

Deprecated since version 1.0.0.

precise_float [bool, default False] Set to enable usage of higher precision (strtod) function when decoding string to double values. Default (False) is to use fast but less precise builtin functionality.

date_unit [str, default None] The timestamp unit to detect if converting dates. The default behaviour is to try and detect the correct precision, but if this is not desired then pass one of ‘s’, ‘ms’, ‘us’ or ‘ns’ to force parsing only seconds, milliseconds, microseconds or nanoseconds respectively.

encoding [str, default is ‘utf-8’] The encoding to use to decode py3 bytes.

encoding_errors [str, optional, default “strict”] How encoding errors are treated. List of possible values .

New in version 1.3.0.

lines [bool, default False] Read the file as a json object per line.

chunksize [int, optional] Return JsonReader object for iteration. See the [line-delimited json docs](#) for more information on chunksize. This can only be passed if *lines=True*. If this is None, the file will be read into memory all at once.

Changed in version 1.2: JsonReader is a context manager.

compression [str or dict, default ‘infer’] For on-the-fly decompression of on-disk data. If ‘infer’ and ‘path_or_buf’ is path-like, then detect compression from the following extensions: ‘.gz’, ‘.bz2’, ‘.zip’, ‘.xz’, or ‘.zst’ (otherwise no compression). If using ‘zip’, the ZIP file must contain only one data file to be read in. Set to None for no decompression. Can also be a dict with key ‘method’ set to one of {'zip', 'gzip', 'bz2', 'zstd'} and other key-value pairs are forwarded to zipfile.ZipFile, gzip.GzipFile, bz2.BZ2File, or zstandard.ZstdDecompressor, respectively. As an example, the following could be passed for Zstandard decompression using a custom compression dictionary: `compression={'method': 'zstd', 'dict_data': my_compression_dict}`.

Changed in version 1.4.0: Zstandard support.

nrows [int, optional] The number of lines from the line-delimited jsonfile that has to be read. This can only be passed if *lines=True*. If this is None, all the rows will be returned.

New in version 1.1.

storage_options [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to `urllib` as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to `fsspec`. Please see `fsspec` and `urllib` for more details.

New in version 1.2.0.

Returns

Series or DataFrame The type returned depends on the value of *typ*.

See also:

`DataFrame.to_json` Convert a DataFrame to a JSON string.

`Series.to_json` Convert a Series to a JSON string.

`json_normalize` Normalize semi-structured JSON data into a flat table.

Notes

Specific to `orient='table'`, if a `DataFrame` with a literal `Index` name of `index` gets written with `to_json()`, the subsequent read operation will incorrectly set the `Index` name to None. This is because `index` is also used by `DataFrame.to_json()` to denote a missing `Index` name, and the subsequent `read_json()` operation cannot distinguish between the two. The same limitation is encountered with a `MultiIndex` and any names beginning with 'level_'.

Examples

```
>>> df = pd.DataFrame([['a', 'b'], ['c', 'd']],
...                     index=['row 1', 'row 2'],
...                     columns=['col 1', 'col 2'])
```

Encoding/decoding a Dataframe using 'split' formatted JSON:

```
>>> df.to_json(orient='split')
'{"columns": ["col 1", "col 2"], "index": ["row 1", "row 2"], "data": [[{"a": "a", "b": "b"}, {"c": "c", "d": "d"}]]}'
>>> pd.read_json(_, orient='split')
   col 1  col 2
row 1      a      b
row 2      c      d
```

Encoding/decoding a Dataframe using 'index' formatted JSON:

```
>>> df.to_json(orient='index')
'{"row 1": {"col 1": "a", "col 2": "b"}, "row 2": {"col 1": "c", "col 2": "d"}}'
```

```
>>> pd.read_json(_, orient='index')
   col 1  col 2
row 1      a      b
row 2      c      d
```

Encoding/decoding a Dataframe using 'records' formatted JSON. Note that index labels are not preserved with this encoding.

```
>>> df.to_json(orient='records')
'[{"col 1": "a", "col 2": "b"}, {"col 1": "c", "col 2": "d"}]'
>>> pd.read_json(_, orient='records')
   col 1  col 2
0      a      b
1      c      d
```

Encoding with Table Schema

```
>>> df.to_json(orient='table')
  [{"schema": {"fields": [{"name": "index", "type": "string"}, {"name": "col 1", "type": "string"}, {"name": "col 2", "type": "string"}], "primaryKey": ["index"], "pandas_version": "1.4.0"}, {"data": [{"index": "row 1", "col 1": "a", "col 2": "b"}, {"index": "row 2", "col 1": "c", "col 2": "d"}]}]
```

pandas.json_normalize

`pandas.json_normalize(data, record_path=None, meta=None, meta_prefix=None, record_prefix=None, errors='raise', sep='.', max_level=None)`

Normalize semi-structured JSON data into a flat table.

Parameters

data [dict or list of dicts] Unserialized JSON objects.

record_path [str or list of str, default None] Path in each object to list of records. If not passed, data will be assumed to be an array of records.

meta [list of paths (str or list of str), default None] Fields to use as metadata for each record in resulting table.

meta_prefix [str, default None] If True, prefix records with dotted (?) path, e.g. foo.bar.field if meta is ['foo', 'bar'].

record_prefix [str, default None] If True, prefix records with dotted (?) path, e.g. foo.bar.field if path to records is ['foo', 'bar'].

errors [{‘raise’, ‘ignore’}, default ‘raise’] Configures error handling.

- ‘ignore’ : will ignore KeyError if keys listed in meta are not always present.
- ‘raise’ : will raise KeyError if keys listed in meta are not always present.

sep [str, default ‘.’] Nested records will generate names separated by sep. e.g., for sep=‘.’, {‘foo’: {‘bar’: 0}} -> foo.bar.

max_level [int, default None] Max number of levels(depth of dict) to normalize. if None, normalizes all levels.

New in version 0.25.0.

Returns

frame [DataFrame]

Normalize semi-structured JSON data into a flat table.

Examples

```
>>> data = [
...     {"id": 1, "name": {"first": "Coleen", "last": "Volk"}},
...     {"name": {"given": "Mark", "family": "Regner"}},
...     {"id": 2, "name": "Faye Raker"},
... ]
>>> pd.json_normalize(data)
   id name.first name.last name.given name.family      name
0   1.0       Coleen      Volk        NaN        NaN      NaN
```

(continues on next page)

(continued from previous page)

1	NaN	NaN	NaN	Mark	Regner	NaN
2	2.0	NaN	NaN	NaN	NaN	Faye Raker

```
>>> data = [
...     {
...         "id": 1,
...         "name": "Cole Volk",
...         "fitness": {"height": 130, "weight": 60},
...     },
...     {"name": "Mark Reg", "fitness": {"height": 130, "weight": 60}},
...     {
...         "id": 2,
...         "name": "Faye Raker",
...         "fitness": {"height": 130, "weight": 60},
...     },
... ]
>>> pd.json_normalize(data, max_level=0)
   id      name      fitness
0  1.0  Cole Volk  {'height': 130, 'weight': 60}
1  NaN    Mark Reg  {'height': 130, 'weight': 60}
2  2.0   Faye Raker  {'height': 130, 'weight': 60}
```

Normalizes nested data up to level 1.

```
>>> data = [
...     {
...         "id": 1,
...         "name": "Cole Volk",
...         "fitness": {"height": 130, "weight": 60},
...     },
...     {"name": "Mark Reg", "fitness": {"height": 130, "weight": 60}},
...     {
...         "id": 2,
...         "name": "Faye Raker",
...         "fitness": {"height": 130, "weight": 60},
...     },
... ]
>>> pd.json_normalize(data, max_level=1)
   id      name  fitness.height  fitness.weight
0  1.0  Cole Volk          130            60
1  NaN    Mark Reg          130            60
2  2.0   Faye Raker          130            60
```

```
>>> data = [
...     {
...         "state": "Florida",
...         "shortname": "FL",
...         "info": {"governor": "Rick Scott"},
...         "counties": [
...             {"name": "Dade", "population": 12345},
...             {"name": "Broward", "population": 400000},
...             {"name": "Palm Beach", "population": 600000},
```

(continues on next page)

(continued from previous page)

```

...     ],
... },
...
...     "state": "Ohio",
...     "shortname": "OH",
...     "info": {"governor": "John Kasich"},
...     "counties": [
...         {"name": "Summit", "population": 1234},
...         {"name": "Cuyahoga", "population": 1337},
...     ],
... },
...
]
>>> result = pd.json_normalize(
...     data, "counties", ["state", "shortname", ["info", "governor"]])
...
>>> result
      name  population    state shortname info.governor
0    Dade        12345  Florida       FL   Rick Scott
1  Broward        40000  Florida       FL   Rick Scott
2  Palm Beach        60000  Florida       FL   Rick Scott
3    Summit        1234    Ohio        OH John Kasich
4   Cuyahoga        1337    Ohio        OH John Kasich

```

```

>>> data = {"A": [1, 2]}
>>> pd.json_normalize(data, "A", record_prefix="Prefix.")
Prefix.0
0    1
1    2

```

Returns normalized data with columns prefixed with the given string.

pandas.DataFrame.to_json

```
DataFrame.to_json(path_or_buf=None, orient=None, date_format=None, double_precision=10,
                   force_ascii=True, date_unit='ms', default_handler=None, lines=False, compression='infer',
                   index=True, indent=None, storage_options=None)
```

Convert the object to a JSON string.

Note NaN's and None will be converted to null and datetime objects will be converted to UNIX timestamps.

Parameters

path_or_buf [str, path object, file-like object, or None, default None] String, path object (implementing os.PathLike[str]), or file-like object implementing a write() function. If None, the result is returned as a string.

orient [str] Indication of expected JSON string format.

- Series:
 - default is ‘index’
 - allowed values are: {‘split’, ‘records’, ‘index’, ‘table’}.
- DataFrame:

- default is ‘columns’
- allowed values are: {‘split’, ‘records’, ‘index’, ‘columns’, ‘values’, ‘table’}.
- The format of the JSON string:
 - ‘split’ : dict like {‘index’ -> [index], ‘columns’ -> [columns], ‘data’ -> [values]}
 - ‘records’ : list like [{column -> value}, … , {column -> value}]
 - ‘index’ : dict like {index -> {column -> value}}
 - ‘columns’ : dict like {column -> {index -> value}}
 - ‘values’ : just the values array
 - ‘table’ : dict like {‘schema’: {schema}, ‘data’: {data}}

Describing the data, where data component is like `orient='records'`.

date_format [{None, ‘epoch’, ‘iso’}] Type of date conversion. ‘epoch’ = epoch milliseconds, ‘iso’ = ISO8601. The default depends on the `orient`. For `orient='table'`, the default is ‘iso’. For all other orients, the default is ‘epoch’.

double_precision [int, default 10] The number of decimal places to use when encoding floating point values.

force_ascii [bool, default True] Force encoded string to be ASCII.

date_unit [str, default ‘ms’ (milliseconds)] The time unit to encode to, governs timestamp and ISO8601 precision. One of ‘s’, ‘ms’, ‘us’, ‘ns’ for second, millisecond, microsecond, and nanosecond respectively.

default_handler [callable, default None] Handler to call if object cannot otherwise be converted to a suitable format for JSON. Should receive a single argument which is the object to convert and return a serialisable object.

lines [bool, default False] If ‘orient’ is ‘records’ write out line-delimited json format. Will throw ValueError if incorrect ‘orient’ since others are not list-like.

compression [str or dict, default ‘infer’] For on-the-fly compression of the output data. If ‘infer’ and ‘path_or_buf’ path-like, then detect compression from the following extensions: ‘.gz’, ‘.bz2’, ‘.zip’, ‘.xz’, or ‘.zst’ (otherwise no compression). Set to None for no compression. Can also be a dict with key ‘method’ set to one of {‘zip’, ‘gzip’, ‘bz2’, ‘zstd’} and other key-value pairs are forwarded to `zipfile.ZipFile`, `gzip.GzipFile`, `bz2.BZ2File`, or `zstandard.ZstdDecompressor`, respectively. As an example, the following could be passed for faster compression and to create a reproducible gzip archive: `compression={‘method’: ‘gzip’, ‘compresslevel’: 1, ‘mtime’: 1}`.

Changed in version 1.4.0: Zstandard support.

index [bool, default True] Whether to include the index values in the JSON string. Not including the index (`index=False`) is only supported when orient is ‘split’ or ‘table’.

indent [int, optional] Length of whitespace used to indent each record.

New in version 1.0.0.

storage_options [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to `urllib` as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to `fsspec`. Please see `fsspec` and `urllib` for more details.

New in version 1.2.0.

Returns

None or str If path_or_buf is None, returns the resulting json format as a string. Otherwise returns None.

See also:

[read_json](#) Convert a JSON string to pandas object.

Notes

The behavior of `indent=0` varies from the stdlib, which does not indent the output but does insert newlines. Currently, `indent=0` and the default `indent=None` are equivalent in pandas, though this may change in a future release.

`orient='table'` contains a ‘`pandas_version`’ field under ‘`schema`’. This stores the version of *pandas* used in the latest revision of the schema.

Examples

```
>>> import json
>>> df = pd.DataFrame(
...     [[ "a", "b"], [ "c", "d"]],
...     index=[ "row 1", "row 2"],
...     columns=[ "col 1", "col 2"],
... )
```

```
>>> result = df.to_json(orient="split")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
{
    "columns": [
        "col 1",
        "col 2"
    ],
    "index": [
        "row 1",
        "row 2"
    ],
    "data": [
        [
            [
                "a",
                "b"
            ],
            [
                [
                    "c",
                    "d"
                ]
            ]
        ]
    ]
}
```

Encoding/decoding a Dataframe using ‘records’ formatted JSON. Note that index labels are not preserved with this encoding.

```
>>> result = df.to_json(orient="records")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
[  
    {  
        "col 1": "a",  
        "col 2": "b"  
    },  
    {  
        "col 1": "c",  
        "col 2": "d"  
    }  
]
```

Encoding/decoding a Dataframe using 'index' formatted JSON:

```
>>> result = df.to_json(orient="index")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
{  
    "row 1": {  
        "col 1": "a",  
        "col 2": "b"  
    },  
    "row 2": {  
        "col 1": "c",  
        "col 2": "d"  
    }  
}
```

Encoding/decoding a Dataframe using 'columns' formatted JSON:

```
>>> result = df.to_json(orient="columns")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
{  
    "col 1": {  
        "row 1": "a",  
        "row 2": "c"  
    },  
    "col 2": {  
        "row 1": "b",  
        "row 2": "d"  
    }  
}
```

Encoding/decoding a Dataframe using 'values' formatted JSON:

```
>>> result = df.to_json(orient="values")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
[  
    [  
        [
```

(continues on next page)

(continued from previous page)

```
"a",
"b"
],
[
    "c",
    "d"
]
]
```

Encoding with Table Schema:

```
>>> result = df.to_json(orient="table")
>>> parsed = json.loads(result)
>>> json.dumps(parsed, indent=4)
{
    "schema": {
        "fields": [
            {
                "name": "index",
                "type": "string"
            },
            {
                "name": "col 1",
                "type": "string"
            },
            {
                "name": "col 2",
                "type": "string"
            }
        ],
        "primaryKey": [
            "index"
        ],
        "pandas_version": "1.4.0"
    },
    "data": [
        {
            "index": "row 1",
            "col 1": "a",
            "col 2": "b"
        },
        {
            "index": "row 2",
            "col 1": "c",
            "col 2": "d"
        }
    ]
}
```

build_table_schema(data[, index, ...])

Create a Table schema from data.

pandas.io.json.build_table_schema

`pandas.io.json.build_table_schema(data, index=True, primary_key=None, version=True)`

Create a Table schema from data.

Parameters

data [Series, DataFrame]

index [bool, default True] Whether to include `data.index` in the schema.

primary_key [bool or None, default True] Column names to designate as the primary key.
The default `None` will set '`primaryKey`' to the index level or levels if the index is unique.

version [bool, default True] Whether to include a field `pandas_version` with the version of pandas that last revised the table schema. This version can be different from the installed pandas version.

Returns

schema [dict]

Notes

See Table Schema for conversion types. Timedeltas as converted to ISO8601 duration format with 9 decimal places after the seconds field for nanosecond precision.

Categoricals are converted to the `any` dtype, and use the `enum` field constraint to list the allowed values. The `ordered` attribute is included in an `ordered` field.

Examples

```
>>> df = pd.DataFrame(
...     {'A': [1, 2, 3],
...      'B': ['a', 'b', 'c'],
...      'C': pd.date_range('2016-01-01', freq='d', periods=3),
...      }, index=pd.Index(range(3), name='idx'))
>>> build_table_schema(df)
{'fields': [{'name': 'idx', 'type': 'integer'}, {'name': 'A', 'type': 'integer'}, {'name': 'B', 'type': 'string'}, {'name': 'C', 'type': 'datetime'}], 'primaryKey': ['idx'], 'pandas_version': '1.4.0'}
```

3.1.6 HTML

<code>read_html(io[, match, flavor, header, ...])</code>	Read HTML tables into a list of DataFrame objects.
<code>DataFrame.to_html([buf, columns, col_space, ...])</code>	Render a DataFrame as an HTML table.

`pandas.read_html`

```
pandas.read_html(io, match='.', flavor=None, header=None, index_col=None, skiprows=None, attrs=None,
                 parse_dates=False, thousands=',', encoding=None, decimal=',', converters=None,
                 na_values=None, keep_default_na=True, displayed_only=True)
```

Read HTML tables into a list of DataFrame objects.

Parameters

io [str, path object, or file-like object] String, path object (implementing `os.PathLike[str]`), or file-like object implementing a string `read()` function. The string can represent a URL or the HTML itself. Note that lxml only accepts the http, ftp and file url protocols. If you have a URL that starts with 'https' you might try removing the 's'.

match [str or compiled regular expression, optional] The set of tables containing text matching this regex or string will be returned. Unless the HTML is extremely simple you will probably need to pass a non-empty string here. Defaults to '.' (match any non-empty string). The default value will return all tables contained on a page. This value is converted to a regular expression so that there is consistent behavior between BeautifulSoup and lxml.

flavor [str, optional] The parsing engine to use. 'bs4' and 'html5lib' are synonymous with each other, they are both there for backwards compatibility. The default of `None` tries to use `lxml` to parse and if that fails it falls back on `bs4 + html5lib`.

header [int or list-like, optional] The row (or list of rows for a `MultiIndex`) to use to make the columns headers.

index_col [int or list-like, optional] The column (or list of columns) to use to create the index.

skiprows [int, list-like or slice, optional] Number of rows to skip after parsing the column integer. 0-based. If a sequence of integers or a slice is given, will skip the rows indexed by that sequence. Note that a single element sequence means 'skip the nth row' whereas an integer means 'skip n rows'.

attrs [dict, optional] This is a dictionary of attributes that you can pass to use to identify the table in the HTML. These are not checked for validity before being passed to lxml or BeautifulSoup. However, these attributes must be valid HTML table attributes to work correctly. For example,

```
attrs = {'id': 'table'}
```

is a valid attribute dictionary because the 'id' HTML tag attribute is a valid HTML attribute for *any* HTML tag as per [this document](#).

```
attrs = {'asdf': 'table'}
```

is *not* a valid attribute dictionary because 'asdf' is not a valid HTML attribute even if it is a valid XML attribute. Valid HTML 4.01 table attributes can be found [here](#). A working draft of the HTML 5 spec can be found [here](#). It contains the latest information on table attributes for the modern web.

parse_dates [bool, optional] See `read_csv()` for more details.

thousands [str, optional] Separator to use to parse thousands. Defaults to ',', '.

encoding [str, optional] The encoding used to decode the web page. Defaults to `None`. ```None``` preserves the previous encoding behavior, which depends on the underlying parser library (e.g., the parser library will try to use the encoding provided by the document).

decimal [str, default '.'] Character to recognize as decimal point (e.g. use ‘,’ for European data).

converters [dict, default None] Dict of functions for converting values in certain columns. Keys can either be integers or column labels, values are functions that take one input argument, the cell (not column) content, and return the transformed content.

na_values [iterable, default None] Custom NA values.

keep_default_na [bool, default True] If na_values are specified and keep_default_na is False the default NaN values are overridden, otherwise they’re appended to.

displayed_only [bool, default True] Whether elements with “display: none” should be parsed.

Returns

dfs A list of DataFrames.

See also:

[read_csv](#) Read a comma-separated values (csv) file into DataFrame.

Notes

Before using this function you should read the [gotchas about the HTML parsing libraries](#).

Expect to do some cleanup after you call this function. For example, you might need to manually assign column names if the column names are converted to NaN when you pass the `header=0` argument. We try to assume as little as possible about the structure of the table and push the idiosyncrasies of the HTML contained in the table to the user.

This function searches for `<table>` elements and only for `<tr>` and `<th>` rows and `<td>` elements within each `<tr>` or `<th>` element in the table. `<td>` stands for “table data”. This function attempts to properly handle `colspan` and `rowspan` attributes. If the function has a `<thead>` argument, it is used to construct the header, otherwise the function attempts to find the header within the body (by putting rows with only `<th>` elements into the header).

Similar to `read_csv()` the `header` argument is applied **after** `skiprows` is applied.

This function will *always* return a list of `DataFrame` or it will fail, e.g., it will *not* return an empty list.

Examples

See the `read_html` documentation in the IO section of the docs for some examples of reading in HTML tables.

pandas.DataFrame.to_html

```
DataFrame.to_html(buf=None, columns=None, col_space=None, header=True, index=True, na_rep='NaN',
                  formatters=None, float_format=None, sparsify=None, index_names=True, justify=None,
                  max_rows=None, max_cols=None, show_dimensions=False, decimal=',', bold_rows=True,
                  classes=None, escape=True, notebook=False, border=None, table_id=None,
                  render_links=False, encoding=None)
```

Render a DataFrame as an HTML table.

Parameters

buf [str, Path or StringIO-like, optional, default None] Buffer to write to. If None, the output is returned as a string.

columns [sequence, optional, default None] The subset of columns to write. Writes all columns by default.

col_space [str or int, list or dict of int or str, optional] The minimum width of each column in CSS length units. An int is assumed to be px units.

New in version 0.25.0: Ability to use str.

header [bool, optional] Whether to print column labels, default True.

index [bool, optional, default True] Whether to print index (row) labels.

na_rep [str, optional, default ‘NaN’] String representation of NaN to use.

formatters [list, tuple or dict of one-param. functions, optional] Formatter functions to apply to columns’ elements by position or name. The result of each function must be a unicode string. List/tuple must be of length equal to the number of columns.

float_format [one-parameter function, optional, default None] Formatter function to apply to columns’ elements if they are floats. This function must return a unicode string and will be applied only to the non-NaN elements, with NaN being handled by na_rep.

Changed in version 1.2.0.

sparsify [bool, optional, default True] Set to False for a DataFrame with a hierarchical index to print every multiindex key at each row.

index_names [bool, optional, default True] Prints the names of the indexes.

justify [str, default None] How to justify the column labels. If None uses the option from the print configuration (controlled by set_option), ‘right’ out of the box. Valid values are

- left
- right
- center
- justify
- justify-all
- start
- end
- inherit
- match-parent
- initial
- unset.

max_rows [int, optional] Maximum number of rows to display in the console.

max_cols [int, optional] Maximum number of columns to display in the console.

show_dimensions [bool, default False] Display DataFrame dimensions (number of rows by number of columns).

decimal [str, default ‘.’] Character recognized as decimal separator, e.g. ‘,’ in Europe.

bold_rows [bool, default True] Make the row labels bold in the output.

classes [str or list or tuple, default None] CSS class(es) to apply to the resulting html table.

escape [bool, default True] Convert the characters <, >, and & to HTML-safe sequences.

notebook [{True, False}, default False] Whether the generated HTML is for IPython Notebook.

border [int] A border=border attribute is included in the opening `<table>` tag. Default `pd.options.display.html.border`.

table_id [str, optional] A css id is included in the opening `<table>` tag if specified.

render_links [bool, default False] Convert URLs to HTML links.

encoding [str, default “utf-8”] Set character encoding.

New in version 1.0.

Returns

str or None If buf is None, returns the result as a string. Otherwise returns None.

See also:

[to_string](#) Convert DataFrame to a string.

`Styler.to_html([buf, table_uuid, ...])`

Write Styler to a file, buffer or string in HTML-CSS format.

pandas.io.formats.style.Styler.to_html

`Styler.to_html(buf=None, *, table_uuid=None, table_attributes=None, sparse_index=None, sparse_columns=None, bold_headers=False, caption=None, max_rows=None, max_columns=None, encoding=None, doctype_html=False, exclude_styles=False, **kwargs)`

Write Styler to a file, buffer or string in HTML-CSS format.

New in version 1.3.0.

Parameters

buf [str, path object, file-like object, or None, default None] String, path object (implementing `os.PathLike[str]`), or file-like object implementing a string `write()` function. If None, the result is returned as a string.

table_uuid [str, optional] Id attribute assigned to the `<table>` HTML element in the format:

`<table id="T_<table_uuid>" ...>`

If not given uses Styler’s initially assigned value.

table_attributes [str, optional] Attributes to assign within the `<table>` HTML element in the format:

`<table ... <table_attributes> >`

If not given defaults to Styler’s preexisting value.

sparse_index [bool, optional] Whether to sparsify the display of a hierarchical index. Setting to False will display each explicit level element in a hierarchical key for each row. Defaults to `pandas.options.styler.sparse.index` value.

New in version 1.4.0.

sparse_columns [bool, optional] Whether to sparsify the display of a hierarchical index. Setting to False will display each explicit level element in a hierarchical key for each column. Defaults to `pandas.options.styler.sparse.columns` value.

New in version 1.4.0.

bold_headers [bool, optional] Adds “font-weight: bold;” as a CSS property to table style header cells.

New in version 1.4.0.

caption [str, optional] Set, or overwrite, the caption on Styler before rendering.

New in version 1.4.0.

max_rows [int, optional] The maximum number of rows that will be rendered. Defaults to `pandas.options.styler.render.max_rows/max_columns`.

New in version 1.4.0.

max_columns [int, optional] The maximum number of columns that will be rendered. Defaults to `pandas.options.styler.render.max_columns`, which is None.

Rows and columns may be reduced if the number of total elements is large. This value is set to `pandas.options.styler.render.max_elements`, which is 262144 (18 bit browser rendering).

New in version 1.4.0.

encoding [str, optional] Character encoding setting for file output, and HTML meta tags. Defaults to `pandas.options.styler.render.encoding` value of “utf-8”.

doctype_html [bool, default False] Whether to output a fully structured HTML file including all HTML elements, or just the core `<style>` and `<table>` elements.

exclude_styles [bool, default False] Whether to include the `<style>` element and all associated element `class` and `id` identifiers, or solely the `<table>` element without styling identifiers.

****kwargs** Any additional keyword arguments are passed through to the jinja2 `self.template.render` process. This is useful when you need to provide additional variables for a custom template.

Returns

str or None If `buf` is None, returns the result as a string. Otherwise returns `None`.

See also:

`DataFrame.to_html` Write a DataFrame to a file, buffer or string in HTML format.

3.1.7 XML

<code>read_xml(path_or_buffer[, xpath, ...])</code>	Read XML document into a DataFrame object.
<code>DataFrame.to_xml([path_or_buffer, index, ...])</code>	Render a DataFrame to an XML document.

pandas.read_xml

```
pandas.read_xml(path_or_buffer, xpath='/*', namespaces=None, elems_only=False, attrs_only=False,
                 names=None, encoding='utf-8', parser='lxml', stylesheet=None, compression='infer',
                 storage_options=None)
```

Read XML document into a DataFrame object.

New in version 1.3.0.

Parameters

path_or_buffer [str, path object, or file-like object] String, path object (implementing `os.PathLike[str]`), or file-like object implementing a `read()` function. The string can be any valid XML string or a path. The string can further be a URL. Valid URL schemes include http, ftp, s3, and file.

xpath [str, optional, default ‘./’] The XPath to parse required set of nodes for migration to DataFrame. XPath should return a collection of elements and not a single element. Note: The etree parser supports limited XPath expressions. For more complex XPath, use `lxml` which requires installation.

namespaces [dict, optional] The namespaces defined in XML document as dicts with key being namespace prefix and value the URI. There is no need to include all namespaces in XML, only the ones used in `xpath` expression. Note: if XML document uses default namespace denoted as `xmlns='<URI>'` without a prefix, you must assign any temporary namespace prefix such as ‘doc’ to the URI in order to parse underlying nodes and/or attributes. For example,

```
namespaces = {"doc": "https://example.com"}
```

elems_only [bool, optional, default False] Parse only the child elements at the specified `xpath`. By default, all child elements and non-empty text nodes are returned.

attrs_only [bool, optional, default False] Parse only the attributes at the specified `xpath`. By default, all attributes are returned.

names [list-like, optional] Column names for DataFrame of parsed XML data. Use this parameter to rename original element names and distinguish same named elements.

encoding [str, optional, default ‘utf-8’] Encoding of XML document.

parser [{‘lxml’, ‘etree’}], default ‘lxml’ Parser module to use for retrieval of data. Only ‘lxml’ and ‘etree’ are supported. With ‘lxml’ more complex XPath searches and ability to use XSLT stylesheet are supported.

stylesheet [str, path object or file-like object] A URL, file-like object, or a raw string containing an XSLT script. This stylesheet should flatten complex, deeply nested XML documents for easier parsing. To use this feature you must have `lxml` module installed and specify ‘lxml’ as `parser`. The `xpath` must reference nodes of transformed XML document generated after XSLT transformation and not the original XML document. Only XSLT 1.0 scripts and not later versions is currently supported.

compression [str or dict, default ‘infer’] For on-the-fly decompression of on-disk data. If ‘infer’ and ‘path_or_buffer’ is path-like, then detect compression from the following extensions: ‘.gz’, ‘.bz2’, ‘.zip’, ‘.xz’, or ‘.zst’ (otherwise no compression). If using ‘zip’, the ZIP file must contain only one data file to be read in. Set to `None` for no decompression. Can also be a dict with key ‘method’ set to one of {‘zip’, ‘gzip’, ‘bz2’, ‘zstd’} and other key-value pairs are forwarded to `zipfile.ZipFile`, `gzip.GzipFile`, `bz2.BZ2File`, or `zstandard.ZstdDecompressor`, respectively. As an example, the follow-

ing could be passed for Zstandard decompression using a custom compression dictionary:
`compression={'method': 'zstd', 'dict_data': my_compression_dict}`.

Changed in version 1.4.0: Zstandard support.

storage_options [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to `urllib` as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to `fsspec`. Please see `fsspec` and `urllib` for more details.

Returns

`df` A DataFrame.

See also:

[`read_json`](#) Convert a JSON string to pandas object.

[`read_html`](#) Read HTML tables into a list of DataFrame objects.

Notes

This method is best designed to import shallow XML documents in following format which is the ideal fit for the two-dimensions of a DataFrame (row by column).

```
<root>
  <row>
    <column1>data</column1>
    <column2>data</column2>
    <column3>data</column3>
    ...
  </row>
  <row>
    ...
  </row>
  ...
</root>
```

As a file format, XML documents can be designed any way including layout of elements and attributes as long as it conforms to W3C specifications. Therefore, this method is a convenience handler for a specific flatter design and not all possible XML structures.

However, for more complex XML documents, `stylesheet` allows you to temporarily redesign original document with XSLT (a special purpose language) for a flatter version for migration to a DataFrame.

This function will *always* return a single `DataFrame` or raise exceptions due to issues with XML document, `xpath`, or other parameters.

Examples

```
>>> xml = '''<?xml version='1.0' encoding='utf-8'?>
... <data xmlns="http://example.com">
...   <row>
...     <shape>square</shape>
...     <degrees>360</degrees>
...     <sides>4.0</sides>
...   </row>
...   <row>
...     <shape>circle</shape>
...     <degrees>360</degrees>
...     <sides/>
...   </row>
...   <row>
...     <shape>triangle</shape>
...     <degrees>180</degrees>
...     <sides>3.0</sides>
...   </row>
... </data>'''
```

```
>>> df = pd.read_xml(xml)
>>> df
      shape  degrees  sides
0    square      360    4.0
1    circle      360     NaN
2  triangle      180    3.0
```

```
>>> xml = '''<?xml version='1.0' encoding='utf-8'?>
... <data>
...   <row shape="square" degrees="360" sides="4.0"/>
...   <row shape="circle" degrees="360"/>
...   <row shape="triangle" degrees="180" sides="3.0"/>
... </data>'''
```

```
>>> df = pd.read_xml(xml, xpath=".//row")
>>> df
      shape  degrees  sides
0    square      360    4.0
1    circle      360     NaN
2  triangle      180    3.0
```

```
>>> xml = '''<?xml version='1.0' encoding='utf-8'?>
... <doc: data xmlns: doc="https://example.com">
...   <doc:row>
...     <doc:shape>square</doc:shape>
...     <doc:degrees>360</doc:degrees>
...     <doc:sides>4.0</doc:sides>
...   </doc:row>
...   <doc:row>
...     <doc:shape>circle</doc:shape>
...     <doc:degrees>360</doc:degrees>
```

(continues on next page)

(continued from previous page)

```

...
<doc:sides/>
...
</doc:row>
...
<doc:row>
...
<doc:shape>triangle</doc:shape>
...
<doc:degrees>180</doc:degrees>
...
<doc:sides>3.0</doc:sides>
...
</doc:row>
...
</doc:data>'''
```

```

>>> df = pd.read_xml(xml,
...                     xpath="//doc:row",
...                     namespaces={"doc": "https://example.com"})
>>> df
   shape  degrees  sides
0  square      360    4.0
1  circle      360     NaN
2 triangle     180    3.0
```

pandas.DataFrame.to_xml

`DataFrame.to_xml(path_or_buffer=None, index=True, root_name='data', row_name='row', na_rep=None, attr_cols=None, elem_cols=None, namespaces=None, prefix=None, encoding='utf-8', xml_declaration=True, pretty_print=True, parser='xml', stylesheet=None, compression='infer', storage_options=None)`

Render a DataFrame to an XML document.

New in version 1.3.0.

Parameters

path_or_buffer [str, path object, file-like object, or None, default None] String, path object (implementing `os.PathLike[str]`), or file-like object implementing a `write()` function. If None, the result is returned as a string.

index [bool, default True] Whether to include index in XML document.

root_name [str, default ‘data’] The name of root element in XML document.

row_name [str, default ‘row’] The name of row element in XML document.

na_rep [str, optional] Missing data representation.

attr_cols [list-like, optional] List of columns to write as attributes in row element. Hierarchical columns will be flattened with underscore delimiting the different levels.

elem_cols [list-like, optional] List of columns to write as children in row element. By default, all columns output as children of row element. Hierarchical columns will be flattened with underscore delimiting the different levels.

namespaces [dict, optional] All namespaces to be defined in root element. Keys of dict should be prefix names and values of dict corresponding URIs. Default namespaces should be given empty string key. For example,

```
namespaces = {"": "https://example.com"}
```

prefix [str, optional] Namespace prefix to be used for every element and/or attribute in document. This should be one of the keys in `namespaces` dict.

encoding [str, default ‘utf-8’] Encoding of the resulting document.

xml_declaration [bool, default True] Whether to include the XML declaration at start of document.

pretty_print [bool, default True] Whether output should be pretty printed with indentation and line breaks.

parser [{‘lxml’, ‘etree’}], default ‘lxml’] Parser module to use for building of tree. Only ‘lxml’ and ‘etree’ are supported. With ‘lxml’, the ability to use XSLT stylesheet is supported.

stylesheet [str, path object or file-like object, optional] A URL, file-like object, or a raw string containing an XSLT script used to transform the raw XML output. Script should use layout of elements and attributes from original output. This argument requires `lxml` to be installed. Only XSLT 1.0 scripts and not later versions is currently supported.

compression [str or dict, default ‘infer’] For on-the-fly compression of the output data. If ‘infer’ and ‘path_or_buffer’ path-like, then detect compression from the following extensions: ‘.gz’, ‘.bz2’, ‘.zip’, ‘.xz’, or ‘.zst’ (otherwise no compression). Set to None for no compression. Can also be a dict with key ‘method’ set to one of {‘zip’, ‘gzip’, ‘bz2’, ‘zstd’} and other key-value pairs are forwarded to `zipfile.ZipFile`, `gzip.GzipFile`, `bz2.BZ2File`, or `zstandard.ZstdDecompressor`, respectively. As an example, the following could be passed for faster compression and to create a reproducible gzip archive: `compression={‘method’: ‘gzip’, ‘compresslevel’: 1, ‘mtime’: 1}`.

Changed in version 1.4.0: Zstandard support.

storage_options [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to `urllib` as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to `fsspec`. Please see `fsspec` and `urllib` for more details.

Returns

None or str If `io` is None, returns the resulting XML format as a string. Otherwise returns None.

See also:

[to_json](#) Convert the pandas object to a JSON string.

[to_html](#) Convert DataFrame to a html.

Examples

```
>>> df = pd.DataFrame({'shape': ['square', 'circle', 'triangle'],
...                      'degrees': [360, 360, 180],
...                      'sides': [4, np.nan, 3]})
```

```
>>> df.to_xml()
<?xml version='1.0' encoding='utf-8'?>
<data>
  <row>
```

(continues on next page)

(continued from previous page)

```
<index>0</index>
<shape>square</shape>
<degrees>360</degrees>
<sides>4.0</sides>

3.1.8 Latex

<code>DataFrame.to_latex([buf, columns, ...])</code>	Render object to a LaTeX tabular, longtable, or nested table.
--	---

pandas.DataFrame.to_latex

```
DataFrame.to_latex(buf=None, columns=None, col_space=None, header=True, index=True, na_rep='NaN',
                   formatters=None, float_format=None, sparsify=None, index_names=True,
                   bold_rows=False, column_format=None, longtable=None, escape=None, encoding=None,
                   decimal=',', multicolumn=None, multicolumn_format=None, multirow=None,
                   caption=None, label=None, position=None)
```

Render object to a LaTeX tabular, longtable, or nested table.

Requires `\usepackage{booktabs}`. The output can be copy/pasted into a main LaTeX document or read from an external file with `\input{table.tex}`.

Changed in version 1.0.0: Added caption and label arguments.

Changed in version 1.2.0: Added position argument, changed meaning of caption argument.

Parameters

buf [str, Path or StringIO-like, optional, default None] Buffer to write to. If None, the output is returned as a string.

columns [list of label, optional] The subset of columns to write. Writes all columns by default.

col_space [int, optional] The minimum width of each column.

header [bool or list of str, default True] Write out the column names. If a list of strings is given, it is assumed to be aliases for the column names.

index [bool, default True] Write row names (index).

na_rep [str, default ‘NaN’] Missing data representation.

formatters [list of functions or dict of {str: function}, optional] Formatter functions to apply to columns’ elements by position or name. The result of each function must be a unicode string. List must be of length equal to the number of columns.

float_format [one-parameter function or str, optional, default None] Formatter for floating point numbers. For example `float_format=".2f"` and `float_format="{:0.2f}"`. `format` will both result in 0.1234 being formatted as 0.12.

sparsify [bool, optional] Set to False for a DataFrame with a hierarchical index to print every multiindex key at each row. By default, the value will be read from the config module.

index_names [bool, default True] Prints the names of the indexes.

bold_rows [bool, default False] Make the row labels bold in the output.

column_format [str, optional] The columns format as specified in [LaTeX table format](#) e.g. ‘rcl’ for 3 columns. By default, ‘l’ will be used for all columns except columns of numbers, which default to ‘r’.

longtable [bool, optional] By default, the value will be read from the pandas config module. Use a longtable environment instead of tabular. Requires adding a `\usepackage{longtable}` to your LaTeX preamble.

escape [bool, optional] By default, the value will be read from the pandas config module.
When set to False prevents from escaping latex special characters in column names.

encoding [str, optional] A string representing the encoding to use in the output file, defaults to ‘utf-8’.

decimal [str, default ‘.’] Character recognized as decimal separator, e.g. ‘,’ in Europe.

multicolumn [bool, default True] Use multicolumn to enhance MultiIndex columns. The default will be read from the config module.

multicolumn_format [str, default ‘l’] The alignment for multicolumns, similar to *column_format*. The default will be read from the config module.

multirow [bool, default False] Use multirow to enhance MultiIndex rows. Requires adding a usepackage{multirow} to your LaTeX preamble. Will print centered labels (instead of top-aligned) across the contained rows, separating groups via clines. The default will be read from the pandas config module.

caption [str or tuple, optional] Tuple (full_caption, short_caption), which results in \caption[short_caption]{full_caption}; if a single string is passed, no short caption will be set.

New in version 1.0.0.

Changed in version 1.2.0: Optionally allow caption to be a tuple (full_caption, short_caption).

label [str, optional] The LaTeX label to be placed inside \label{} in the output. This is used with \ref{} in the main .tex file.

New in version 1.0.0.

position [str, optional] The LaTeX positional argument for tables, to be placed after \begin{} in the output.

New in version 1.2.0.

Returns

str or None If buf is None, returns the result as a string. Otherwise returns None.

See also:

[Styler.to_latex](#) Render a DataFrame to LaTeX with conditional formatting.

[DataFrame.to_string](#) Render a DataFrame to a console-friendly tabular output.

[DataFrame.to_html](#) Render a DataFrame as an HTML table.

Examples

```
>>> df = pd.DataFrame(dict(name=['Raphael', 'Donatello'],
...                         mask=['red', 'purple'],
...                         weapon=['sai', 'bo staff']))
>>> print(df.to_latex(index=False))
\begin{tabular}{lll}
\toprule
name & mask & weapon \\
\midrule
Raphael & red & sai \\

```

(continues on next page)

(continued from previous page)

```
Donatello & purple & bo staff \\
\bottomrule
\end{tabular}
```

<code>Styler.to_latex([buf, column_format, ...])</code>	Write Styler to a file, buffer or string in LaTeX format.
---	---

`pandas.io.formats.style.Styler.to_latex`

`Styler.to_latex(buf=None, *, column_format=None, position=None, position_float=None, clines=None, label=None, caption=None, sparse_index=None, sparse_columns=None, multirow_align=None, multicol_align=None, siunitx=False, environment=None, encoding=None, convert_css=False)`

Write Styler to a file, buffer or string in LaTeX format.

New in version 1.3.0.

Parameters

buf [str, path object, file-like object, or None, default None] String, path object (implementing `os.PathLike[str]`), or file-like object implementing a string `write()` function. If None, the result is returned as a string.

column_format [str, optional] The LaTeX column specification placed in location:

```
\begin{tabular}{<column_format>}
```

Defaults to ‘l’ for index and non-numeric data columns, and, for numeric data columns, to ‘r’ by default, or ‘S’ if `siunitx` is True.

position [str, optional] The LaTeX positional argument (e.g. ‘h!’) for tables, placed in location:

```
\begin{table}[<position>].
```

position_float [{"centering", "raggedleft", "raggedright"}, optional] The LaTeX float command placed in location:

```
\begin{table}[<position>]
```

```
<position_float>
```

Cannot be used if `environment` is “longtable”.

hrules [bool] Set to `True` to add `\toprule`, `\midrule` and `\bottomrule` from the `{booktabs}` LaTeX package. Defaults to `pandas.options.styler.latex.hrules`, which is `False`.

Changed in version 1.4.0.

clines [str, optional] Use to control adding `\cline` commands for the index labels separation. Possible values are:

- `None`: no cline commands are added (default).
- “`all;data`”: a cline is added for every index value extending the width of the table, including data entries.
- “`all;index`”: as above with lines extending only the width of the index entries.
- “`skip-last;data`”: a cline is added for each index value except the last level (which is never sparsified), extending the width of the table.

- “skip-last;index”: as above with lines extending only the width of the index entries.

New in version 1.4.0.

label [str, optional] The LaTeX label included as: `\label{<label>}`. This is used with `\ref{<label>}` in the main .tex file.

caption [str, tuple, optional] If string, the LaTeX table caption included as: `\caption{<caption>}`. If tuple, i.e (“full caption”, “short caption”), the caption included as: `\caption[<caption[1]>]{<caption[0]>}`.

sparse_index [bool, optional] Whether to sparsify the display of a hierarchical index. Setting to False will display each explicit level element in a hierarchical key for each row. Defaults to `pandas.options.styler.sparse.index`, which is *True*.

sparse_columns [bool, optional] Whether to sparsify the display of a hierarchical index. Setting to False will display each explicit level element in a hierarchical key for each column. Defaults to `pandas.options.styler.sparse.columns`, which is *True*.

multirow_align [{“c”, “t”, “b”, “naive”}, optional] If sparsifying hierarchical MultiIndexes whether to align text centrally, at the top or bottom using the multirow package. If not given defaults to `pandas.options.styler.latex.multirow_align`, which is “c”. If “naive” is given renders without multirow.

Changed in version 1.4.0.

multicolumn_align [{“r”, “c”, “l”, “naive-l”, “naive-r”}, optional] If sparsifying hierarchical MultiIndex columns whether to align text at the left, centrally, or at the right. If not given defaults to `pandas.options.styler.latex.multicolumn_align`, which is “r”. If a naive option is given renders without multicolumn. Pipe decorators can also be added to non-naive values to draw vertical rules, e.g. “|r” will draw a rule on the left side of right aligned merged cells.

Changed in version 1.4.0.

siunitx [bool, default False] Set to True to structure LaTeX compatible with the {siunitx} package.

environment [str, optional] If given, the environment that will replace ‘table’ in `\begin{table}`. If ‘longtable’ is specified then a more suitable template is rendered. If not given defaults to `pandas.options.styler.latex.environment`, which is *None*.

New in version 1.4.0.

encoding [str, optional] Character encoding setting. Defaults to `pandas.options.styler.render.encoding`, which is “utf-8”.

convert_css [bool, default False] Convert simple cell-styles from CSS to LaTeX format. Any CSS not found in conversion table is dropped. A style can be forced by adding option `-latex`. See notes.

Returns

str or None If `buf` is None, returns the result as a string. Otherwise returns *None*.

See also:

Styler.format Format the text display value of cells.

Notes

Latex Packages

For the following features we recommend the following LaTeX inclusions:

Feature	Inclusion
sparse columns	none: included within default {tabular} environment
sparse rows	\usepackage{multirow}
hrules	\usepackage{booktabs}
colors	\usepackage[table]{xcolor}
siunitx	\usepackage{siunitx}
bold (with siunitx)	\usepackage{etoolbox} \robustify\bfseries \sisetup{detect-all = true} (<i>within {document}</i>)
italic (with siunitx)	\usepackage{etoolbox} \robustify\itshape \sisetup{detect-all = true} (<i>within {document}</i>)
environment	\usepackage{longtable} if arg is “longtable” or any other relevant environment package
hyperlinks	\usepackage{hyperref}

Cell Styles

LaTeX styling can only be rendered if the accompanying styling functions have been constructed with appropriate LaTeX commands. All styling functionality is built around the concept of a CSS (<attribute>, <value>) pair (see *Table Visualization*), and this should be replaced by a LaTeX (<command>, <options>) approach. Each cell will be styled individually using nested LaTeX commands with their accompanied options.

For example the following code will highlight and bold a cell in HTML-CSS:

```
>>> df = pd.DataFrame([[1,2], [3,4]])
>>> s = df.style.highlight_max(axis=None,
...                               props='background-color:red; font-weight:bold;')
>>> s.to_html()
```

The equivalent using LaTeX only commands is the following:

```
>>> s = df.style.highlight_max(axis=None,
...                               props='cellcolor:{red}; bfseries: ;')
>>> s.to_latex()
```

Internally these structured LaTeX (<command>, <options>) pairs are translated to the `display_value` with the default structure: \<command>\<options> <display_value>. Where there are multiple commands the latter is nested recursively, so that the above example highlighted cell is rendered as \cellcolor{red} \bfseries 4.

Occasionally this format does not suit the applied command, or combination of LaTeX packages that is in use, so additional flags can be added to the <options>, within the tuple, to result in different positions of required braces (the `default` being the same as `--nowrap`):

Tuple Format	Output Structure
(<command>, <options>)	\<command><options> <display_value>
(<command>, <options> --nowrap)	\<command><options> <display_value>
(<command>, <options> --rwrap)	\<command><options>{ <display_value> }
(<command>, <options> --wrap)	{\<command><options> <display_value>}
(<command>, <options> --lwrap)	{\<command><options>} <display_value>
(<command>, <options> --dwrap)	{\<command><options>} { <display_value> }

For example the `textbf` command for font-weight should always be used with `--rwrap` so `('textbf', '--rwrap')` will render a working cell, wrapped with braces, as `\textbf{<display_value>}`.

A more comprehensive example is as follows:

```
>>> df = pd.DataFrame([[1, 2.2, "dogs"], [3, 4.4, "cats"], [2, 6.6, "cows"]],
...                   index=["ix1", "ix2", "ix3"],
...                   columns=["Integers", "Floats", "Strings"])
>>> s = df.style.highlight_max(
...     props='cellcolor:[HTML]{FFFF00}; color:{red};'
...           'textit:--rwrap; textbf:--rwrap;'
... )
>>> s.to_latex()
```

	Integers	Floats	Strings
ix1	1	2.200000	dogs
ix2	3	4.400000	cats
ix3	2	6.600000	cows

Table Styles

Internally Styler uses its `table_styles` object to parse the `column_format`, `position`, `position_float`, and `label` input arguments. These arguments are added to table styles in the format:

```
set_table_styles([
    {"selector": "column_format", "props": f":{column_format};"},
    {"selector": "position", "props": f":{position};"},
    {"selector": "position_float", "props": f":{position_float};"},
    {"selector": "label", "props": f":{{label.replace(':', '$')}};"}
], overwrite=False)
```

Exception is made for the `hrules` argument which, in fact, controls all three commands: `toprule`, `bottomrule` and `midrule` simultaneously. Instead of setting `hrules` to `True`, it is also possible to set each individual rule definition, by manually setting the `table_styles`, for example below we set a regular `toprule`, set an `hline` for `bottomrule` and exclude the `midrule`:

```
set_table_styles([
    {'selector': 'toprule', 'props': ':toprule;'},
    {'selector': 'bottomrule', 'props': ':hline;'},
], overwrite=False)
```

If other commands are added to table styles they will be detected, and positioned immediately above the `\begin{tabular}` command. For example to add odd and even row coloring, from the `{colortbl}` package, in format `\rowcolors{1}{pink}{red}`, use:

```
set_table_styles([
    {'selector': 'rowcolors', 'props': ':{1}{pink}{red};'}
], overwrite=False)
```

A more comprehensive example using these arguments is as follows:

```
>>> df.columns = pd.MultiIndex.from_tuples([
...     ("Numeric", "Integers"),
...     ("Numeric", "Floats"),
...     ("Non-Numeric", "Strings")
... ])
>>> df.index = pd.MultiIndex.from_tuples([
...     ("L0", "ix1"), ("L0", "ix2"), ("L1", "ix3")
... ])
>>> s = df.style.highlight_max(
...     props='cellcolor:[HTML]{FFFF00}; color:{red}; itshape:; bfseries:;'
... )
>>> s.to_latex(
...     column_format="rrrr", position="h", position_float="centering",
...     hrules=True, label="table:5", caption="Styled LaTeX Table",
...     multirow_align="t", multicol_align="r"
... )
```

Table 1: Styled LaTeX Table

		Numeric	Non-Numeric
	Integers	Floats	Strings
L0	ix1	1	2.200000
	ix2	3	4.400000
L1	ix3	2	6.600000

Formatting

To format values `Styler.format()` should be used prior to calling `Styler.to_latex`, as well as other methods such as `Styler.hide()` for example:

```
>>> s.clear()
>>> s.table_styles = []
>>> s.caption = None
>>> s.format({
...     ("Numeric", "Integers"): '\$\{\}',
...     ("Numeric", "Floats"): '{:.3f}',
...     ("Non-Numeric", "Strings"): str.upper
... })
      Numeric      Non-Numeric
      Integers   Floats   Strings
L0    ix1       $1    2.200    DOGS
      ix2       $3    4.400    CATS
L1    ix3       $2    6.600    COWS
```

```
>>> s.to_latex()
\begin{tabular}{llrrrl}
```

(continues on next page)

(continued from previous page)

```
{} & {} & \multicolumn{2}{r}{Numeric} & {Non-Numeric} \\
{} & {} & {Integers} & {Floats} & {Strings} \\
\multirow[c]{2}{*}{L0} & ix1 & \$1 & 2.200 & DOGS \\
& ix2 & \$3 & 4.400 & CATS \\
L1 & ix3 & \$2 & 6.600 & COWS \\
\end{tabular}
```

CSS Conversion

This method can convert a Styler constructed with HTML-CSS to LaTeX using the following limited conversions.

CSS Attribute	CSS value	LaTeX Command	LaTeX Options
font-weight	bold bolder	bfseries bfseries	
font-style	italic oblique	itshape slshape	
background-color	red #fe01ea #f0e rgb(128,255,0) rgba(128,0,0,0.5) rgb(25%,255,50%)	cellcolor	{red}-lwrap [HTML]{FE01EA}-lwrap [HTML]{FF00EE}-lwrap [rgb]{0.5,1,0}-lwrap [rgb]{0.5,0,0}-lwrap [rgb]{0.25,1,0.5}-lwrap
color	red #fe01ea #f0e rgb(128,255,0) rgba(128,0,0,0.5) rgb(25%,255,50%)	color	{red} [HTML]{FE01EA} [HTML]{FF00EE} [rgb]{0.5,1,0} [rgb]{0.5,0,0} [rgb]{0.25,1,0.5}

It is also possible to add user-defined LaTeX only styles to a HTML-CSS Styler using the `--latex` flag, and to add LaTeX parsing options that the converter will detect within a CSS-comment.

```
>>> df = pd.DataFrame([[1]])
>>> df.style.set_properties(
...     **{"font-weight": "bold /* --dwrap */", "Huge": "--latex--rwrap"}
... ).to_latex(convert_css=True)
\begin{tabular}{lr}
```

(continues on next page)

(continued from previous page)

```
{} & {0} \\
0 & {\bfseries}{\Huge{1}} \\
\end{tabular}
```

Examples

Below we give a complete step by step example adding some advanced features and noting some common gotchas.

First we create the DataFrame and Styler as usual, including MultiIndex rows and columns, which allow for more advanced formatting options:

```
>>> cidx = pd.MultiIndex.from_arrays([
...     ["Equity", "Equity", "Equity", "Equity",
...      "Stats", "Stats", "Stats", "Rating"],
...     ["Energy", "Energy", "Consumer", "Consumer", "", "", "", ""],
...     ["BP", "Shell", "H&M", "Unilever",
...      "Std Dev", "Variance", "52w High", "52w Low", ""]
... ])
>>> iidx = pd.MultiIndex.from_arrays([
...     ["Equity", "Equity", "Equity", "Equity"],
...     ["Energy", "Energy", "Consumer", "Consumer"],
...     ["BP", "Shell", "H&M", "Unilever"]
... ])
>>> styler = pd.DataFrame([
...     [1, 0.8, 0.66, 0.72, 32.1678, 32.1678**2, 335.12, 240.89, "Buy"],
...     [0.8, 1.0, 0.69, 0.79, 1.876, 1.876**2, 14.12, 19.78, "Hold"],
...     [0.66, 0.69, 1.0, 0.86, 7, 7**2, 210.9, 140.6, "Buy"],
...     [0.72, 0.79, 0.86, 1.0, 213.76, 213.76**2, 2807, 3678, "Sell"],
... ], columns=cidx, index=iidx).style
```

Second we will format the display and, since our table is quite wide, will hide the repeated level-0 of the index:

```
>>> styler.format(subset="Equity", precision=2)
...     .format(subset="Stats", precision=1, thousands=",")
...     .format(subset="Rating", formatter=str.upper)
...     .format_index(escape="latex", axis=1)
...     .format_index(escape="latex", axis=0)
...     .hide(level=0, axis=0)
```

Note that one of the string entries of the index and column headers is “H&M”. Without applying the *escape*=“*latex*” option to the *format_index* method the resultant LaTeX will fail to render, and the error returned is quite difficult to debug. Using the appropriate escape the “&” is converted to “\&”.

Thirdly we will apply some (CSS-HTML) styles to our object. We will use a builtin method and also define our own method to highlight the stock recommendation:

```
>>> def rating_color(v):
...     if v == "Buy": color = "#33ff85"
...     elif v == "Sell": color = "#ff5933"
...     else: color = "#ffdd33"
...     return f"color: {color}; font-weight: bold;"
>>> styler.background_gradient(cmap="inferno", subset="Equity", vmin=0, vmax=1)
...     .applymap(rating_color, subset="Rating")
```

All the above styles will work with HTML (see below) and LaTeX upon conversion:

	Equity								Stats	Rating
	Energy		Consumer							
	BP	Shell	H&M	Unilever	Std Dev	Variance	52w High	52w Low		
Energy	BP	1.00	0.80	0.66	0.72	32.2	1,034.8	335.1	240.9	BUY
	Shell	0.80	1.00	0.69	0.79	1.9	3.5	14.1	19.8	HOLD
Consumer	H&M	0.66	0.69	1.00	0.86	7.0	49.0	210.9	140.6	BUY
	Unilever	0.72	0.79	0.86	1.00	213.8	45,693.3	2,807.0	3,678.0	SELL

However, we finally want to add one LaTeX only style (from the `{graphicx}` package), that is not easy to convert from CSS and pandas does not support it. Notice the `-latex` flag used here, as well as `-rwrap` to ensure this is formatted correctly and not ignored upon conversion.

```
>>> styler.applymap_index(  
...     lambda v: "rotatebox:{45}--rwrap--latex;", level=2, axis=1  
... )
```

Finally we render our LaTeX adding in other options as required:

```
>>> styler.to_latex()
...     caption="Selected stock correlation and simple statistics.",
...     clines="skip-last;data",
...     convert_css=True,
...     position_float="centering",
...     multicol_align="|c|",
...     hrules=True,
... )
\begin{table}
\centering
\caption{Selected stock correlation and simple statistics.}
\begin{tabular}{llrrrrrrrrl}
\toprule
& & \multicolumn{4}{|c|}{Equity} & \multicolumn{4}{|c|}{Stats} & Rating \\
& & \multicolumn{2}{|c|}{Energy} & \multicolumn{2}{|c|}{Consumer} &
\multicolumn{4}{|c|}{} & \\
& & \rotatebox{45}{BP} & \rotatebox{45}{Shell} & \rotatebox{45}{H\&M} &
\rotatebox{45}{Unilever} & \rotatebox{45}{Std Dev} & \rotatebox{45}{Variance} &
\rotatebox{45}{52w High} & \rotatebox{45}{52w Low} & \rotatebox{45}{} \\
\midrule
\multirow[c]{2}{*}{Energy} & BP & {\cellcolor[HTML]{FCFFA4}}
\color[HTML]{000000} 1.00 & {\cellcolor[HTML]{FCA50A}} \color[HTML]{000000}
0.80 & {\cellcolor[HTML]{EB6628}} \color[HTML]{F1F1F1} 0.66 &
{\cellcolor[HTML]{F68013}} \color[HTML]{F1F1F1} 0.72 & 32.2 & 1,034.8 & 335.1
& 240.9 & \color[HTML]{33FF85} \bfseries BUY \\
& Shell & {\cellcolor[HTML]{FCA50A}} \color[HTML]{000000} 0.80 &
{\cellcolor[HTML]{FCFFA4}} \color[HTML]{000000} 1.00 &
{\cellcolor[HTML]{F1731D}} \color[HTML]{F1F1F1} 0.69 &
```

(continues on next page)

(continued from previous page)

```

3.1.9 HDFStore: PyTables (HDF5)

<code>read_hdf(path_or_buf[, key, mode, errors, ...])</code>	Read from the store, close it if we opened it.
<code>HDFStore.put(key, value[, format, index, ...])</code>	Store object in HDFStore.
<code>HDFStore.append(key, value[, format, axes, ...])</code>	Append to Table in file.
<code>HDFStore.get(key)</code>	Retrieve pandas object stored in file.
<code>HDFStore.select(key[, where, start, stop, ...])</code>	Retrieve pandas object stored in file, optionally based on where criteria.
<code>HDFStore.info()</code>	Print detailed information on the store.
<code>HDFStore.keys([include])</code>	Return a list of keys corresponding to objects stored in HDFStore.
<code>HDFStore.groups()</code>	Return a list of all the top-level nodes.
<code>HDFStore.walk([where])</code>	Walk the pytables group hierarchy for pandas objects.

`pandas.read_hdf`

```
pandas.read_hdf(path_or_buf, key=None, mode='r', errors='strict', where=None, start=None, stop=None,  
                 columns=None, iterator=False, chunksize=None, **kwargs)
```

Read from the store, close it if we opened it.

Retrieve pandas object stored in file, optionally based on where criteria.

Warning: Pandas uses PyTables for reading and writing HDF5 files, which allows serializing object-dtype data with pickle when using the “fixed” format. Loading pickled data received from untrusted sources can be unsafe.

See: <https://docs.python.org/3/library/pickle.html> for more.

Parameters

path_or_buf [str, path object, pandas.HDFStore] Any valid string path is acceptable. Only supports the local file system, remote URLs and file-like objects are not supported.

If you want to pass in a path object, pandas accepts any `os.PathLike`.

Alternatively, pandas accepts an open `pandas.HDFStore` object.

key [object, optional] The group identifier in the store. Can be omitted if the HDF file contains a single pandas object.

mode [{‘r’, ‘r+’, ‘a’}, default ‘r’] Mode to use when opening the file. Ignored if `path_or_buf` is a `pandas.HDFStore`. Default is ‘r’.

errors [str, default ‘strict’] Specifies how encoding and decoding errors are to be handled. See the `errors` argument for `open()` for a full list of options.

where [list, optional] A list of Term (or convertible) objects.

start [int, optional] Row number to start selection.

stop [int, optional] Row number to stop selection.

columns [list, optional] A list of columns names to return.

iterator [bool, optional] Return an iterator object.

chunksize [int, optional] Number of rows to include in an iteration when using an iterator.

****kwargs** Additional keyword arguments passed to `HDFStore`.

Returns

item [object] The selected object. Return type depends on the object stored.

See also:

`DataFrame.to_hdf` Write a HDF file from a DataFrame.

`HDFStore` Low-level access to HDF files.

Examples

```
>>> df = pd.DataFrame([[1, 1.0, 'a']], columns=['x', 'y', 'z'])
>>> df.to_hdf('./store.h5', 'data')
>>> reread = pd.read_hdf('./store.h5')
```

pandas.HDFStore.put

`HDFStore.put(key, value, format=None, index=True, append=False, complib=None, complevel=None, min_itemsize=None, nan_rep=None, data_columns=None, encoding=None, errors='strict', track_times=True, dropna=False)`

Store object in HDFStore.

Parameters

key [str]

value [{Series, DataFrame}]

format ['fixed(f)|table(t)', default is 'fixed'] Format to use when storing object in HDFStore.

Value can be one of:

'**fixed**' Fixed format. Fast writing/reading. Not-appendable, nor searchable.

'**table**' Table format. Write as a PyTables Table structure which may perform worse but allow more flexible operations like searching / selecting subsets of the data.

append [bool, default False] This will force Table format, append the input data to the existing.

data_columns [list of columns or True, default None] List of columns to create as data columns, or True to use all columns. See [here](#).

encoding [str, default None] Provide an encoding for strings.

track_times [bool, default True] Parameter is propagated to 'create_table' method of 'PyTables'. If set to False it enables to have the same h5 files (same hashes) independent on creation time.

New in version 1.1.0.

pandas.HDFStore.append

`HDFStore.append(key, value, format=None, axes=None, index=True, append=True, complib=None, complevel=None, columns=None, min_itemsize=None, nan_rep=None, chunkszie=None, expectedrows=None, dropna=None, data_columns=None, encoding=None, errors='strict')`

Append to Table in file. Node must already exist and be Table format.

Parameters

key [str]

value [{Series, DataFrame}]

format ['table' is the default] Format to use when storing object in HDFStore. Value can be one of:

'**table**' Table format. Write as a PyTables Table structure which may perform worse but allow more flexible operations like searching / selecting subsets of the data.

append [bool, default True] Append the input data to the existing.

data_columns [list of columns, or True, default None] List of columns to create as indexed data columns for on-disk queries, or True to use all columns. By default only the axes of the object are indexed. See [here](#).

min_itemsize [dict of columns that specify minimum str sizes]

nan_rep [str to use as str nan representation]

chunksize [size to chunk the writing]

expectedrows [expected TOTAL row size of this table]

encoding [default None, provide an encoding for str]

dropna [bool, default False] Do not write an ALL nan row to the store settable by the option ‘io.hdf.dropna_table’.

Notes

Does *not* check if data being appended overlaps with existing data in the table, so be careful

pandas.HDFStore.get

`HDFStore.get(key)`

Retrieve pandas object stored in file.

Parameters

key [str]

Returns

object Same type as object stored in file.

pandas.HDFStore.select

`HDFStore.select(key, where=None, start=None, stop=None, columns=None, iterator=False, chunksize=None, auto_close=False)`

Retrieve pandas object stored in file, optionally based on where criteria.

Warning: Pandas uses PyTables for reading and writing HDF5 files, which allows serializing object-dtype data with pickle when using the “fixed” format. Loading pickled data received from untrusted sources can be unsafe.

See: <https://docs.python.org/3/library/pickle.html> for more.

Parameters

key [str] Object being retrieved from file.

where [list or None] List of Term (or convertible) objects, optional.

start [int or None] Row number to start selection.

stop [int, default None] Row number to stop selection.

columns [list or None] A list of columns that if not None, will limit the return columns.

iterator [bool or False] Returns an iterator.

chunksize [int or None] Number of rows to include in iteration, return an iterator.

auto_close [bool or False] Should automatically close the store when finished.

Returns

object Retrieved object from file.

pandas.HDFStore.info

HDFStore.info()

Print detailed information on the store.

Returns

str

pandas.HDFStore.keys

HDFStore.keys(include='pandas')

Return a list of keys corresponding to objects stored in HDFStore.

Parameters

include [str, default ‘pandas’] When kind equals ‘pandas’ return pandas objects. When kind equals ‘native’ return native HDF5 Table objects.

New in version 1.1.0.

Returns

list List of ABSOLUTE path-names (e.g. have the leading ‘/’).

Raises

raises ValueError if kind has an illegal value

pandas.HDFStore.groups

HDFStore.groups()

Return a list of all the top-level nodes.

Each node returned is not a pandas storage object.

Returns

list List of objects.

pandas.HDFStore.walk

HDFStore.walk(where='/')

Walk the pytables group hierarchy for pandas objects.

This generator will yield the group path, subgroups and pandas object names for each group.

Any non-pandas PyTables objects that are not a group will be ignored.

The *where* group itself is listed first (preorder), then each of its child groups (following an alphanumerical order) is also traversed, following the same procedure.

Parameters

where [str, default “/”] Group where to start walking.

Yields

path [str] Full path to a group (without trailing ‘/’).

groups [list] Names (strings) of the groups contained in *path*.

leaves [list] Names (strings) of the pandas objects contained in *path*.

Warning: One can store a subclass of *DataFrame* or *Series* to HDF5, but the type of the subclass is lost upon storing.

3.1.10 Feather

<code>read_feather(path[, columns, use_threads, ...])</code>	Load a feather-format object from the file path.
<code>DataFrame.to_feather(path, **kwargs)</code>	Write a DataFrame to the binary Feather format.

pandas.read_feather

`pandas.read_feather(path, columns=None, use_threads=True, storage_options=None)`

Load a feather-format object from the file path.

Parameters

path [str, path object, or file-like object] String, path object (implementing `os.PathLike[str]`), or file-like object implementing a binary `read()` function. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. A local file could be: `file:///localhost/path/to/table.feather`.

columns [sequence, default None] If not provided, all columns are read.

use_threads [bool, default True] Whether to parallelize reading using multiple threads.

storage_options [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to `urllib` as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to `fsspec`. Please see `fsspec` and `urllib` for more details.

New in version 1.2.0.

Returns

type of object stored in file

pandas.DataFrame.to_feather

`DataFrame.to_feather(path, **kwargs)`

Write a DataFrame to the binary Feather format.

Parameters

path [str, path object, file-like object] String, path object (implementing `os.PathLike[str]`), or file-like object implementing a binary `write()` function. If a string or a path, it will be used as Root Directory path when writing a partitioned dataset.

****kwargs** : Additional keywords passed to `pyarrow.feather.write_feather()`. Starting with pyarrow 0.17, this includes the `compression`, `compression_level`, `chunksize` and `version` keywords.

New in version 1.1.0.

Notes

This function writes the dataframe as a [feather file](#). Requires a default index. For saving the DataFrame with your custom index use a method that supports custom indices e.g. `to_parquet`.

3.1.11 Parquet

<code>read_parquet(path[, engine, columns, ...])</code>	Load a parquet object from the file path, returning a DataFrame.
<code>DataFrame.to_parquet([path, engine, ...])</code>	Write a DataFrame to the binary parquet format.

pandas.read_parquet

`pandas.read_parquet(path, engine='auto', columns=None, storage_options=None, use_nullable_dtypes=False, **kwargs)`

Load a parquet object from the file path, returning a DataFrame.

Parameters

path [str, path object or file-like object] String, path object (implementing `os.PathLike[str]`), or file-like object implementing a binary `read()` function. The string could be a URL. Valid URL schemes include http, ftp, s3, gs, and file. For file URLs, a host is expected. A local file could be: `file://localhost/path/to/table.parquet`. A file URL can also be a path to a directory that contains multiple partitioned parquet files. Both pyarrow and fastparquet support paths to directories as well as file URLs. A directory path could be: `file://localhost/path/to/tables` or `s3://bucket/partition_dir`.

engine [{‘auto’, ‘pyarrow’, ‘fastparquet’}], default ‘auto’] Parquet library to use. If ‘auto’, then the option `io.parquet.engine` is used. The default `io.parquet.engine` behavior is to try ‘pyarrow’, falling back to ‘fastparquet’ if ‘pyarrow’ is unavailable.

columns [list, default=None] If not None, only these columns will be read from the file.

storage_options [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to `urllib` as header options. For other URLs (e.g. starting with “s3://”, and

“gcs://”) the key-value pairs are forwarded to `fsspec`. Please see `fsspec` and `urllib` for more details.

New in version 1.3.0.

use_nullable_dtypes [bool, default False] If True, use dtypes that use `pd.NA` as missing value indicator for the resulting DataFrame. (only applicable for the pyarrow engine) As new dtypes are added that support `pd.NA` in the future, the output with this option will change to use those dtypes. Note: this is an experimental option, and behaviour (e.g. additional support dtypes) may change without notice.

New in version 1.2.0.

****kwargs** Any additional kwargs are passed to the engine.

Returns

`DataFrame`

`pandas.DataFrame.to_parquet`

`DataFrame.to_parquet(path=None, engine='auto', compression='snappy', index=None, partition_cols=None, storage_options=None, **kwargs)`

Write a DataFrame to the binary parquet format.

This function writes the dataframe as a [parquet file](#). You can choose different parquet backends, and have the option of compression. See [the user guide](#) for more details.

Parameters

path [str, path object, file-like object, or None, default None] String, path object (implementing `os.PathLike[str]`), or file-like object implementing a binary `write()` function. If None, the result is returned as bytes. If a string or path, it will be used as Root Directory path when writing a partitioned dataset.

Changed in version 1.2.0.

Previously this was “fname”

engine [{‘auto’, ‘pyarrow’, ‘fastparquet’}, default ‘auto’] Parquet library to use. If ‘auto’, then the option `io.parquet.engine` is used. The default `io.parquet.engine` behavior is to try ‘pyarrow’, falling back to ‘fastparquet’ if ‘pyarrow’ is unavailable.

compression [{‘snappy’, ‘gzip’, ‘brotli’, None}, default ‘snappy’] Name of the compression to use. Use None for no compression.

index [bool, default None] If True, include the dataframe’s index(es) in the file output. If False, they will not be written to the file. If None, similar to True the dataframe’s index(es) will be saved. However, instead of being saved as values, the RangeIndex will be stored as a range in the metadata so it doesn’t require much space and is faster. Other indexes will be included as columns in the file output.

partition_cols [list, optional, default None] Column names by which to partition the dataset. Columns are partitioned in the order they are given. Must be None if path is not a string.

storage_options [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to `urllib` as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to `fsspec`. Please see `fsspec` and `urllib` for more details.

New in version 1.2.0.

****kwargs** Additional arguments passed to the parquet library. See [pandas io](#) for more details.

Returns

bytes if no path argument is provided else None

See also:

[read_parquet](#) Read a parquet file.

[DataFrame.to_csv](#) Write a csv file.

[DataFrame.to_sql](#) Write to a sql table.

[DataFrame.to_hdf](#) Write to hdf.

Notes

This function requires either the `fastparquet` or `pyarrow` library.

Examples

```
>>> df = pd.DataFrame(data={'col1': [1, 2], 'col2': [3, 4]})  
>>> df.to_parquet('df.parquet.gzip',  
...                 compression='gzip')  
>>> pd.read_parquet('df.parquet.gzip')  
   col1  col2  
0      1      3  
1      2      4
```

If you want to get a buffer to the parquet content you can use a `io.BytesIO` object, as long as you don't use `partition_cols`, which creates multiple files.

```
>>> import io  
>>> f = io.BytesIO()  
>>> df.to_parquet(f)  
>>> f.seek(0)  
0  
>>> content = f.read()
```

3.1.12 ORC

`read_orc(path[, columns])`

Load an ORC object from the file path, returning a DataFrame.

`pandas.read_orc`

`pandas.read_orc(path, columns=None, **kwargs)`

Load an ORC object from the file path, returning a DataFrame.

New in version 1.0.0.

Parameters

path [str, path object, or file-like object] String, path object (implementing `os.PathLike[str]`), or file-like object implementing a binary `read()` function. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. A local file could be: `file:///localhost/path/to/table.orc`.

columns [list, default None] If not None, only these columns will be read from the file.

****kwargs** Any additional kwargs are passed to pyarrow.

Returns

`DataFrame`

Notes

Before using this function you should read the [user guide about ORC](#) and [install optional dependencies](#).

3.1.13 SAS

`read_sas(filepath_or_buffer[, format, ...])`

Read SAS files stored as either XPORT or SAS7BDAT format files.

`pandas.read_sas`

`pandas.read_sas(filepath_or_buffer, format=None, index=None, encoding=None, chunksize=None, iterator=False)`

Read SAS files stored as either XPORT or SAS7BDAT format files.

Parameters

filepath_or_buffer [str, path object, or file-like object] String, path object (implementing `os.PathLike[str]`), or file-like object implementing a binary `read()` function. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. A local file could be: `file:///localhost/path/to/table.sas`.

format [str {‘xport’, ‘sas7bdat’} or None] If None, file format is inferred from file extension. If ‘xport’ or ‘sas7bdat’, uses the corresponding format.

index [identifier of index column, defaults to None] Identifier of column that should be used as index of the DataFrame.

encoding [str, default is None] Encoding for text data. If None, text data are stored as raw bytes.

chunksize [int] Read file `chunksize` lines at a time, returns iterator.

Changed in version 1.2: `TextFileReader` is a context manager.

iterator [bool, defaults to False] If True, returns an iterator for reading the file incrementally.

Changed in version 1.2: TextFileReader is a context manager.

Returns

DataFrame if iterator=False and chunksize=None, else **SAS7BDATReader**
or **XportReader**

3.1.14 SPSS

<code>read_spss(path[, usecols, convert_categoricals])</code>	Load an SPSS file from the file path, returning a DataFrame.
---	--

pandas.read_spss

`pandas.read_spss(path, usecols=None, convert_categoricals=True)`

Load an SPSS file from the file path, returning a DataFrame.

New in version 0.25.0.

Parameters

path [str or Path] File path.

usecols [list-like, optional] Return a subset of the columns. If None, return all columns.

convert_categoricals [bool, default is True] Convert categorical columns into pd.Categorical.

Returns

DataFrame

3.1.15 SQL

<code>read_sql_table(table_name, con[, schema, ...])</code>	Read SQL database table into a DataFrame.
<code>read_sql_query(sql, con[, index_col, ...])</code>	Read SQL query into a DataFrame.
<code>read_sql(sql, con[, index_col, ...])</code>	Read SQL query or database table into a DataFrame.
<code>DataFrame.to_sql(name, con[, schema, ...])</code>	Write records stored in a DataFrame to a SQL database.

pandas.read_sql_table

`pandas.read_sql_table(table_name, con, schema=None, index_col=None, coerce_float=True, parse_dates=None, columns=None, chunksize=None)`

Read SQL database table into a DataFrame.

Given a table name and a SQLAlchemy connectable, returns a DataFrame. This function does not support DBAPI connections.

Parameters

table_name [str] Name of SQL table in database.

con [SQLAlchemy connectable or str] A database URI could be provided as str. SQLite DBAPI connection mode not supported.

schema [str, default None] Name of SQL schema in database to query (if database flavor supports this). Uses default schema if None (default).

index_col [str or list of str, optional, default: None] Column(s) to set as index(MultiIndex).

coerce_float [bool, default True] Attempts to convert values of non-string, non-numeric objects (like decimal.Decimal) to floating point. Can result in loss of Precision.

parse_dates [list or dict, default None]

- List of column names to parse as dates.
- Dict of {column_name: format string} where format string is strftime compatible in case of parsing string times or is one of (D, s, ns, ms, us) in case of parsing integer timestamps.
- Dict of {column_name: arg dict}, where the arg dict corresponds to the keyword arguments of `pandas.to_datetime()` Especially useful with databases without native Datetime support, such as SQLite.

columns [list, default None] List of column names to select from SQL table.

chunksize [int, default None] If specified, returns an iterator where `chunksize` is the number of rows to include in each chunk.

Returns

DataFrame or Iterator[DataFrame] A SQL table is returned as two-dimensional data structure with labeled axes.

See also:

`read_sql_query` Read SQL query into a DataFrame.

`read_sql` Read SQL query or database table into a DataFrame.

Notes

Any datetime values with time zone information will be converted to UTC.

Examples

```
>>> pd.read_sql_table('table_name', 'postgres:///db_name')
```

pandas.read_sql_query

`pandas.read_sql_query(sql, con, index_col=None, coerce_float=True, params=None, parse_dates=None, chunksize=None, dtype=None)`

Read SQL query into a DataFrame.

Returns a DataFrame corresponding to the result set of the query string. Optionally provide an `index_col` parameter to use one of the columns as the index, otherwise default integer index will be used.

Parameters

sql [str SQL query or SQLAlchemy Selectable (select or text object)] SQL query to be executed.

con [SQLAlchemy connectable, str, or sqlite3 connection] Using SQLAlchemy makes it possible to use any DB supported by that library. If a DBAPI2 object, only sqlite3 is supported.

index_col [str or list of str, optional, default: None] Column(s) to set as index(MultiIndex).

coerce_float [bool, default True] Attempts to convert values of non-string, non-numeric objects (like decimal.Decimal) to floating point. Useful for SQL result sets.

params [list, tuple or dict, optional, default: None] List of parameters to pass to execute method. The syntax used to pass parameters is database driver dependent. Check your database driver documentation for which of the five syntax styles, described in PEP 249's paramstyle, is supported. Eg. for psycopg2, uses %(name)s so use params={'name' : 'value'}.

parse_dates [list or dict, default: None]

- List of column names to parse as dates.
- Dict of {column_name: format string} where format string is strftime compatible in case of parsing string times, or is one of (D, s, ns, ms, us) in case of parsing integer timestamps.
- Dict of {column_name: arg dict}, where the arg dict corresponds to the keyword arguments of [pandas.to_datetime\(\)](#) Especially useful with databases without native Datetime support, such as SQLite.

chunksize [int, default None] If specified, return an iterator where *chunksize* is the number of rows to include in each chunk.

dtype [Type name or dict of columns] Data type for data or columns. E.g. np.float64 or {'a': np.float64, 'b': np.int32, 'c': 'Int64'}.

New in version 1.3.0.

Returns

DataFrame or Iterator[DataFrame]

See also:

[read_sql_table](#) Read SQL database table into a DataFrame.

[read_sql](#) Read SQL query or database table into a DataFrame.

Notes

Any datetime values with time zone information parsed via the *parse_dates* parameter will be converted to UTC.

[pandas.read_sql](#)

```
pandas.read_sql(sql, con, index_col=None, coerce_float=True, params=None, parse_dates=None,  
                columns=None, chunksize=None)
```

Read SQL query or database table into a DataFrame.

This function is a convenience wrapper around `read_sql_table` and `read_sql_query` (for backward compatibility). It will delegate to the specific function depending on the provided input. A SQL query will be routed to `read_sql_query`, while a database table name will be routed to `read_sql_table`. Note that the delegated function might have more specific notes about their functionality not listed here.

Parameters

sql [str or SQLAlchemy Selectable (select or text object)] SQL query to be executed or a table name.

con [SQLAlchemy connectable, str, or sqlite3 connection] Using SQLAlchemy makes it possible to use any DB supported by that library. If a DBAPI2 object, only sqlite3 is supported. The user is responsible for engine disposal and connection closure for the SQLAlchemy connectable; str connections are closed automatically. See [here](#).

index_col [str or list of str, optional, default: None] Column(s) to set as index(MultiIndex).

coerce_float [bool, default True] Attempts to convert values of non-string, non-numeric objects (like decimal.Decimal) to floating point, useful for SQL result sets.

params [list, tuple or dict, optional, default: None] List of parameters to pass to execute method. The syntax used to pass parameters is database driver dependent. Check your database driver documentation for which of the five syntax styles, described in PEP 249's paramstyle, is supported. Eg. for psycopg2, uses %(name)s so use params={'name' : 'value'}.

parse_dates [list or dict, default: None]

- List of column names to parse as dates.
- Dict of {column_name: format string} where format string is strftime compatible in case of parsing string times, or is one of (D, s, ns, ms, us) in case of parsing integer timestamps.
- Dict of {column_name: arg dict}, where the arg dict corresponds to the keyword arguments of [pandas.to_datetime\(\)](#) Especially useful with databases without native Datetime support, such as SQLite.

columns [list, default: None] List of column names to select from SQL table (only used when reading a table).

chunksize [int, default None] If specified, return an iterator where *chunksize* is the number of rows to include in each chunk.

Returns

DataFrame or Iterator[DataFrame]

See also:

[**read_sql_table**](#) Read SQL database table into a DataFrame.

[**read_sql_query**](#) Read SQL query into a DataFrame.

Examples

Read data from SQL via either a SQL query or a SQL tablename. When using a SQLite database only SQL queries are accepted, providing only the SQL tablename will result in an error.

```
>>> from sqlite3 import connect
>>> conn = connect(':memory:')
>>> df = pd.DataFrame(data=[[0, '10/11/12'], [1, '12/11/10']],
...                     columns=['int_column', 'date_column'])
>>> df.to_sql('test_data', conn)
2
```

```
>>> pd.read_sql('SELECT int_column, date_column FROM test_data', conn)
      int_column  date_column
0            0    10/11/12
1            1   12/11/10
```

```
>>> pd.read_sql('test_data', 'postgres:///db_name')
```

Apply date parsing to columns through the `parse_dates` argument

```
>>> pd.read_sql('SELECT int_column, date_column FROM test_data',
...               conn,
...               parse_dates=["date_column"])
      int_column  date_column
0            0  2012-10-11
1            1  2010-12-11
```

The `parse_dates` argument calls `pd.to_datetime` on the provided columns. Custom argument values for applying `pd.to_datetime` on a column are specified via a dictionary format:

1. Ignore errors while parsing the values of “`date_column`”

```
>>> pd.read_sql('SELECT int_column, date_column FROM test_data',
...               conn,
...               parse_dates={"date_column": {"errors": "ignore"}})
      int_column  date_column
0            0  2012-10-11
1            1  2010-12-11
```

2. Apply a dayfirst date parsing order on the values of “`date_column`”

```
>>> pd.read_sql('SELECT int_column, date_column FROM test_data',
...               conn,
...               parse_dates={"date_column": {"dayfirst": True}})
      int_column  date_column
0            0  2012-11-10
1            1  2010-11-12
```

3. Apply custom formatting when date parsing the values of “`date_column`”

```
>>> pd.read_sql('SELECT int_column, date_column FROM test_data',
...               conn,
...               parse_dates={"date_column": {"format": "%d/%m/%y"}})
      int_column  date_column
0            0  2012-11-10
1            1  2010-11-12
```

`pandas.DataFrame.to_sql`

```
DataFrame.to_sql(name, con, schema=None, if_exists='fail', index=True, index_label=None, chunksize=None, dtype=None, method=None)
```

Write records stored in a DataFrame to a SQL database.

Databases supported by SQLAlchemy [1] are supported. Tables can be newly created, appended to, or overwritten.

Parameters

name [str] Name of SQL table.

con [sqlalchemy.engine.Engine or Connection] or sqlite3.Connection] Using SQLAlchemy makes it possible to use any DB supported by that library. Legacy support is provided for sqlite3.Connection objects. The user is responsible for engine disposal and connection closure for the SQLAlchemy connectable See [here](#).

schema [str, optional] Specify the schema (if database flavor supports this). If None, use default schema.

if_exists [{‘fail’, ‘replace’, ‘append’}, default ‘fail’] How to behave if the table already exists.

- fail: Raise a ValueError.
- replace: Drop the table before inserting new values.
- append: Insert new values to the existing table.

index [bool, default True] Write DataFrame index as a column. Uses *index_label* as the column name in the table.

index_label [str or sequence, default None] Column label for index column(s). If None is given (default) and *index* is True, then the index names are used. A sequence should be given if the DataFrame uses MultiIndex.

chunksize [int, optional] Specify the number of rows in each batch to be written at a time. By default, all rows will be written at once.

dtype [dict or scalar, optional] Specifying the datatype for columns. If a dictionary is used, the keys should be the column names and the values should be the SQLAlchemy types or strings for the sqlite3 legacy mode. If a scalar is provided, it will be applied to all columns.

method [{None, ‘multi’, callable}, optional] Controls the SQL insertion clause used:

- None : Uses standard SQL INSERT clause (one per row).
- ‘multi’: Pass multiple values in a single INSERT clause.
- callable with signature (pd_table, conn, keys, data_iter).

Details and a sample callable implementation can be found in the section [insert method](#).

Returns

None or int Number of rows affected by to_sql. None is returned if the callable passed into method does not return the number of rows.

The number of returned rows affected is the sum of the `rowcount` attribute of `sqlite3.Cursor` or SQLAlchemy connectable which may not reflect the exact number of written rows as stipulated in the `sqlite3` or `SQLAlchemy`.

New in version 1.4.0.

Raises

ValueError When the table already exists and *if_exists* is ‘fail’ (the default).

See also:

[read_sql](#) Read a DataFrame from a table.

Notes

Timezone aware datetime columns will be written as `Timestamp` with `timezone` type with SQLAlchemy if supported by the database. Otherwise, the datetimes will be stored as timezone unaware timestamps local to the original timezone.

References

[1], [2]

Examples

Create an in-memory SQLite database.

```
>>> from sqlalchemy import create_engine
>>> engine = create_engine('sqlite://', echo=False)
```

Create a table from scratch with 3 rows.

```
>>> df = pd.DataFrame({'name' : ['User 1', 'User 2', 'User 3']})
>>> df
   name
0 User 1
1 User 2
2 User 3
```

```
>>> df.to_sql('users', con=engine)
3
>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 1'), (1, 'User 2'), (2, 'User 3')]
```

An `sqlalchemy.engine.Connection` can also be passed to `con`:

```
>>> with engine.begin() as connection:
...     df1 = pd.DataFrame({'name' : ['User 4', 'User 5']})
...     df1.to_sql('users', con=connection, if_exists='append')
2
```

This is allowed to support operations that require that the same DBAPI connection is used for the entire operation.

```
>>> df2 = pd.DataFrame({'name' : ['User 6', 'User 7']})
>>> df2.to_sql('users', con=engine, if_exists='append')
2
>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 1'), (1, 'User 2'), (2, 'User 3'),
 (0, 'User 4'), (1, 'User 5'), (0, 'User 6'),
 (1, 'User 7')]
```

Overwrite the table with just df2.

```
>>> df2.to_sql('users', con=engine, if_exists='replace',
...             index_label='id')
2
>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 6'), (1, 'User 7')]
```

Specify the dtype (especially useful for integers with missing values). Notice that while pandas is forced to store the data as floating point, the database supports nullable integers. When fetching the data with Python, we get back integer scalars.

```
>>> df = pd.DataFrame({'A': [1, None, 2]})
>>> df
   A
0  1.0
1  NaN
2  2.0
```

```
>>> from sqlalchemy.types import Integer
>>> df.to_sql('integers', con=engine, index=False,
...            dtype={'A': Integer()})
3
```

```
>>> engine.execute("SELECT * FROM integers").fetchall()
[(1,), (None,), (2,)]
```

3.1.16 Google BigQuery

`read_gbq(query[, project_id, index_col, ...])`

Load data from Google BigQuery.

`pandas.read_gbq`

`pandas.read_gbq(query, project_id=None, index_col=None, col_order=None, reauth=False,`
`auth_local_webserver=False, dialect=None, location=None, configuration=None,`
`credentials=None, use_bqstorage_api=None, max_results=None, progress_bar_type=None)`

Load data from Google BigQuery.

This function requires the `pandas-gbq` package.

See the [How to authenticate with Google BigQuery](#) guide for authentication instructions.

Parameters

`query` [str] SQL-Like Query to return data values.

`project_id` [str, optional] Google BigQuery Account project ID. Optional when available from the environment.

`index_col` [str, optional] Name of result column to use for index in results DataFrame.

`col_order` [list(str), optional] List of BigQuery column names in the desired order for results DataFrame.

reauth [bool, default False] Force Google BigQuery to re-authenticate the user. This is useful if multiple accounts are used.

auth_local_webserver [bool, default False] Use the `local webserver flow` instead of the `console flow` when getting user credentials.

New in version 0.2.0 of pandas-gbq.

dialect [str, default ‘legacy’] Note: The default value is changing to ‘standard’ in a future version.

SQL syntax dialect to use. Value can be one of:

‘legacy’ Use BigQuery’s legacy SQL dialect. For more information see [BigQuery Legacy SQL Reference](#).

‘standard’ Use BigQuery’s standard SQL, which is compliant with the SQL 2011 standard. For more information see [BigQuery Standard SQL Reference](#).

location [str, optional] Location where the query job should run. See the [BigQuery locations documentation](#) for a list of available locations. The location must match that of any datasets used in the query.

New in version 0.5.0 of pandas-gbq.

configuration [dict, optional] Query config parameters for job processing. For example:

```
configuration = {‘query’: {‘useQueryCache’: False}}
```

For more information see [BigQuery REST API Reference](#).

credentials [google.auth.credentials.Credentials, optional] Credentials for accessing Google APIs. Use this parameter to override default credentials, such as to use Compute Engine `google.auth.compute_engine.Credentials` or Service Account `google.oauth2.service_account.Credentials` directly.

New in version 0.8.0 of pandas-gbq.

use_bqstorage_api [bool, default False] Use the [BigQuery Storage API](#) to download query results quickly, but at an increased cost. To use this API, first enable it in the [Cloud Console](#). You must also have the `bigrquery.readsessions.create` permission on the project you are billing queries to.

This feature requires version 0.10.0 or later of the `pandas-gbq` package. It also requires the `google-cloud-bigquery-storage` and `fastavro` packages.

New in version 0.25.0.

max_results [int, optional] If set, limit the maximum number of rows to fetch from the query results.

New in version 0.12.0 of pandas-gbq.

New in version 1.1.0.

progress_bar_type [Optional, str] If set, use the `tqdm` library to display a progress bar while the data downloads. Install the `tqdm` package to use this feature.

Possible values of `progress_bar_type` include:

None No progress bar.

‘tqdm’ Use the `tqdm.tqdm()` function to print a progress bar to `sys.stderr`.

‘tqdm_notebook’ Use the `tqdm.tqdm_notebook()` function to display a progress bar as a Jupyter notebook widget.

'`tqdm_gui`' Use the `tqdm.tqdm_gui()` function to display a progress bar as a graphical dialog box.

Note that this feature requires version 0.12.0 or later of the `pandas-gbq` package. And it requires the `tqdm` package. Slightly different than `pandas-gbq`, here the default is `None`.

New in version 1.0.0.

Returns

`df: DataFrame` DataFrame representing results of query.

See also:

`pandas_gbq.read_gbq` This function in the `pandas-gbq` library.

`DataFrame.to_gbq` Write a DataFrame to Google BigQuery.

3.1.17 STATA

<code>read_stata(filepath_or_buffer[, ...])</code>	Read Stata file into DataFrame.
<code>DataFrame.to_stata(path[, convert_dates, ...])</code>	Export DataFrame object to Stata dta format.

`pandas.read_stata`

`pandas.read_stata(filepath_or_buffer, convert_dates=True, convert_categoricals=True, index_col=None, convert_missing=False, preserve_dtypes=True, columns=None, order_categoricals=True, chunksize=None, iterator=False, compression='infer', storage_options=None)`

Read Stata file into DataFrame.

Parameters

filepath_or_buffer [str, path object or file-like object] Any valid string path is acceptable. The string could be a URL. Valid URL schemes include http, ftp, s3, and file. For file URLs, a host is expected. A local file could be: `file:///localhost/path/to/table.dta`.

If you want to pass in a path object, pandas accepts any `os.PathLike`.

By file-like object, we refer to objects with a `read()` method, such as a file handle (e.g. via builtin `open` function) or `StringIO`.

convert_dates [bool, default True] Convert date variables to DataFrame time values.

convert_categoricals [bool, default True] Read value labels and convert columns to Categorical/Factor variables.

index_col [str, optional] Column to set as index.

convert_missing [bool, default False] Flag indicating whether to convert missing values to their Stata representations. If False, missing values are replaced with `nan`. If True, columns containing missing values are returned with object data types and missing values are represented by `StataMissingValue` objects.

preserve_dtypes [bool, default True] Preserve Stata datatypes. If False, numeric data are upcast to pandas default types for foreign data (`float64` or `int64`).

columns [list or None] Columns to retain. Columns will be returned in the given order. None returns all columns.

order_categoricals [bool, default True] Flag indicating whether converted categorical data are ordered.

chunksize [int, default None] Return StataReader object for iterations, returns chunks with given number of lines.

iterator [bool, default False] Return StataReader object.

compression [str or dict, default ‘infer’] For on-the-fly decompression of on-disk data. If ‘infer’ and ‘%s’ is path-like, then detect compression from the following extensions: ‘.gz’, ‘.bz2’, ‘.zip’, ‘.xz’, or ‘.zst’ (otherwise no compression). If using ‘zip’, the ZIP file must contain only one data file to be read in. Set to None for no decompression. Can also be a dict with key ‘method’ set to one of {‘zip’, ‘gzip’, ‘bz2’, ‘zstd’} and other key-value pairs are forwarded to zipfile.ZipFile, gzip.GzipFile, bz2.BZ2File, or zstandard.ZstdDecompressor, respectively. As an example, the following could be passed for Zstandard decompression using a custom compression dictionary: `compression={‘method’: ‘zstd’, ‘dict_data’: my_compression_dict}`.

storage_options [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to urllib as header options. For other URLs (e.g. starting with “s3://”, and “gcs://”) the key-value pairs are forwarded to fsspec. Please see fsspec and urllib for more details.

Returns

DataFrame or StataReader

See also:

io.stata.StataReader Low-level reader for Stata data files.

DataFrame.to_stata Export Stata data files.

Notes

Categorical variables read through an iterator may not have the same categories and dtype. This occurs when a variable stored in a DTA file is associated to an incomplete set of value labels that only label a strict subset of the values.

Examples

Creating a dummy stata for this example >>> df = pd.DataFrame({‘animal’: [‘falcon’, ‘parrot’, ‘falcon’, … ‘parrot’], … ‘speed’: [350, 18, 361, 15]}) # doctest: +SKIP >>> df.to_stata(‘animals.dta’) # doctest: +SKIP

Read a Stata dta file:

```
>>> df = pd.read_stata('animals.dta')
```

Read a Stata dta file in 10,000 line chunks: >>> values = np.random.randint(0, 10, size=(20_000, 1), dtype=“uint8”) # doctest: +SKIP >>> df = pd.DataFrame(values, columns=[“i”]) # doctest: +SKIP >>> df.to_stata(‘filename.dta’) # doctest: +SKIP

```
>>> itr = pd.read_stata('filename.dta', chunksize=10000)
>>> for chunk in itr:
...     # Operate on a single chunk, e.g., chunk.mean()
...     pass
```

`pandas.DataFrame.to_stata`

```
DataFrame.to_stata(path, convert_dates=None, write_index=True, byteorder=None, time_stamp=None,  
                    data_label=None, variable_labels=None, version=114, convert_strl=None,  
                    compression='infer', storage_options=None, *, value_labels=None)
```

Export DataFrame object to Stata dta format.

Writes the DataFrame to a Stata dataset file. “dta” files contain a Stata dataset.

Parameters

path [str, path object, or buffer] String, path object (implementing `os.PathLike[str]`), or file-like object implementing a binary `write()` function.

Changed in version 1.0.0.

Previously this was “fname”

convert_dates [dict] Dictionary mapping columns containing datetime types to stata internal format to use when writing the dates. Options are ‘tc’, ‘td’, ‘tm’, ‘tw’, ‘th’, ‘tq’, ‘ty’. Column can be either an integer or a name. Datetime columns that do not have a conversion type specified will be converted to ‘tc’. Raises `NotImplementedError` if a datetime column has timezone information.

write_index [bool] Write the index to Stata dataset.

byteorder [str] Can be “>”, “<”, “little”, or “big”. default is `sys.byteorder`.

time_stamp [datetime] A datetime to use as file creation date. Default is the current time.

data_label [str, optional] A label for the data set. Must be 80 characters or smaller.

variable_labels [dict] Dictionary containing columns as keys and variable labels as values. Each label must be 80 characters or smaller.

version [{114, 117, 118, 119, None}, default 114] Version to use in the output dta file. Set to None to let pandas decide between 118 or 119 formats depending on the number of columns in the frame. Version 114 can be read by Stata 10 and later. Version 117 can be read by Stata 13 or later. Version 118 is supported in Stata 14 and later. Version 119 is supported in Stata 15 and later. Version 114 limits string variables to 244 characters or fewer while versions 117 and later allow strings with lengths up to 2,000,000 characters. Versions 118 and 119 support Unicode characters, and version 119 supports more than 32,767 variables.

Version 119 should usually only be used when the number of variables exceeds the capacity of dta format 118. Exporting smaller datasets in format 119 may have unintended consequences, and, as of November 2020, Stata SE cannot read version 119 files.

Changed in version 1.0.0: Added support for formats 118 and 119.

convert_strl [list, optional] List of column names to convert to string columns to Stata StrL format. Only available if version is 117. Storing strings in the StrL format can produce smaller dta files if strings have more than 8 characters and values are repeated.

compression [str or dict, default ‘infer’] For on-the-fly compression of the output data. If ‘infer’ and ‘path’ path-like, then detect compression from the following extensions: ‘.gz’, ‘.bz2’, ‘.zip’, ‘.xz’, or ‘.zst’ (otherwise no compression). Set to None for no compression. Can also be a dict with key ‘method’ set to one of {‘zip’, ‘gzip’, ‘bz2’, ‘zstd’} and other key-value pairs are forwarded to `zipfile.ZipFile`, `gzip.GzipFile`, `bz2.BZ2File`, or `zstandard.ZstdDecompressor`, respectively. As an example, the following could be passed for faster compression and to create a reproducible gzip archive: `compression={‘method’: ‘gzip’, ‘compresslevel’: 1, ‘mtime’: 1}`.

New in version 1.1.0.

Changed in version 1.4.0: Zstandard support.

storage_options [dict, optional] Extra options that make sense for a particular storage connection, e.g. host, port, username, password, etc. For HTTP(S) URLs the key-value pairs are forwarded to `urllib` as header options. For other URLs (e.g. starting with “`s3://`”, and “`gcs://`”) the key-value pairs are forwarded to `fsspec`. Please see `fsspec` and `urllib` for more details.

New in version 1.2.0.

value_labels [dict of dicts] Dictionary containing columns as keys and dictionaries of column value to labels as values. Labels for a single variable must be 32,000 characters or smaller.

New in version 1.4.0.

Raises

NotImplementedError

- If datetimes contain timezone information
- Column dtype is not representable in Stata

ValueError

- Columns listed in `convert_dates` are neither `datetime64[ns]` or `datetime.datetime`
- Column listed in `convert_dates` is not in DataFrame
- Categorical label contains more than 32,000 characters

See also:

[read_stata](#) Import Stata data files.

[io.StataWriter](#) Low-level writer for Stata data files.

[io.StataWriter117](#) Low-level writer for version 117 files.

Examples

```
>>> df = pd.DataFrame({'animal': ['falcon', 'parrot', 'falcon',
...                                'parrot'],
...                     'speed': [350, 18, 361, 15]})  
>>> df.to_stata('animals.dta')
```

StataReader.data_label	Return data label of Stata file.
StataReader.value_labels()	Return a dict, associating each variable name a dict, associating each value its corresponding label.
StataReader.variable_labels()	Return variable labels as a dict, associating each variable name with corresponding label.
StataWriter.write_file()	Export DataFrame object to Stata dta format.

`pandas.io.stata.StataReader.data_label`

`property StataReader.data_label`

Return data label of Stata file.

`pandas.io.stata.StataReader.value_labels`

`StataReader.value_labels()`

Return a dict, associating each variable name a dict, associating each value its corresponding label.

Returns

`dict`

`pandas.io.stata.StataReader.variable_labels`

`StataReader.variable_labels()`

Return variable labels as a dict, associating each variable name with corresponding label.

Returns

`dict`

`pandas.io.stata.StataWriter.write_file`

`StataWriter.write_file()`

Export DataFrame object to Stata dta format.

3.2 General functions

3.2.1 Data manipulations

<code>melt(frame[, id_vars, value_vars, var_name, ...])</code>	Unpivot a DataFrame from wide to long format, optionally leaving identifiers set.
<code>pivot(data[, index, columns, values])</code>	Return reshaped DataFrame organized by given index / column values.
<code>pivot_table(data[, values, index, columns, ...])</code>	Create a spreadsheet-style pivot table as a DataFrame.
<code>crosstab(index, columns[, values, rownames, ...])</code>	Compute a simple cross tabulation of two (or more) factors.
<code>cut(x, bins[, right, labels, retbins, ...])</code>	Bin values into discrete intervals.
<code>qcut(x, q[, labels, retbins, precision, ...])</code>	Quantile-based discretization function.
<code>merge(left, right[, how, on, left_on, ...])</code>	Merge DataFrame or named Series objects with a database-style join.
<code>merge_ordered(left, right[, on, left_on, ...])</code>	Perform a merge for ordered data with optional filling/interpolation.
<code>merge_asof(left, right[, on, left_on, ...])</code>	Perform a merge by key distance.
<code>concat(objs[, axis, join, ignore_index, ...])</code>	Concatenate pandas objects along a particular axis with optional set logic along the other axes.
<code>get_dummies(data[, prefix, prefix_sep, ...])</code>	Convert categorical variable into dummy/indicator variables.

continues on next page

Table 24 – continued from previous page

<code>factorize(values[, sort, na_sentinel, size_hint])</code>	Encode the object as an enumerated type or categorical variable.
<code>unique(values)</code>	Return unique values based on a hash table.
<code>wide_to_long(df, stubnames, i, j[, sep, suffix])</code>	Unpivot a DataFrame from wide to long format.

pandas.melt

`pandas.melt(frame, id_vars=None, value_vars=None, var_name=None, value_name='value', col_level=None, ignore_index=True)`

Unpivot a DataFrame from wide to long format, optionally leaving identifiers set.

This function is useful to massage a DataFrame into a format where one or more columns are identifier variables (*id_vars*), while all other columns, considered measured variables (*value_vars*), are “unpivoted” to the row axis, leaving just two non-identifier columns, ‘variable’ and ‘value’.

Parameters

id_vars [tuple, list, or ndarray, optional] Column(s) to use as identifier variables.

value_vars [tuple, list, or ndarray, optional] Column(s) to unpivot. If not specified, uses all columns that are not set as *id_vars*.

var_name [scalar] Name to use for the ‘variable’ column. If None it uses `frame.columns.name` or ‘variable’.

value_name [scalar, default ‘value’] Name to use for the ‘value’ column.

col_level [int or str, optional] If columns are a MultiIndex then use this level to melt.

ignore_index [bool, default True] If True, original index is ignored. If False, the original index is retained. Index labels will be repeated as necessary.

New in version 1.1.0.

Returns

DataFrame Unpivoted DataFrame.

See also:

`DataFrame.melt` Identical method.

`pivot_table` Create a spreadsheet-style pivot table as a DataFrame.

`DataFrame.pivot` Return reshaped DataFrame organized by given index / column values.

`DataFrame.explode` Explode a DataFrame from list-like columns to long format.

Notes

Reference [the user guide](#) for more examples.

Examples

```
>>> df = pd.DataFrame({'A': {0: 'a', 1: 'b', 2: 'c'},
...                      'B': {0: 1, 1: 3, 2: 5},
...                      'C': {0: 2, 1: 4, 2: 6}})

>>> df
   A  B  C
0  a  1  2
1  b  3  4
2  c  5  6
```

```
>>> pd.melt(df, id_vars=['A'], value_vars=['B'])
      A variable  value
0   a          B      1
1   b          B      3
2   c          B      5
```

```
>>> pd.melt(df, id_vars=['A'], value_vars=['B', 'C'])
      A variable  value
0   a          B      1
1   b          B      3
2   c          B      5
3   a          C      2
4   b          C      4
5   c          C      6
```

The names of ‘variable’ and ‘value’ columns can be customized:

```
>>> pd.melt(df, id_vars=['A'], value_vars=['B'],
...            var_name='myVarname', value_name='myValname')
      A myVarname  myValname
0   a          B      1
1   b          B      3
2   c          B      5
```

Original index values can be kept around:

```
>>> pd.melt(df, id_vars=['A'], value_vars=['B', 'C'], ignore_index=False)
      A variable  value
0   a          B      1
1   b          B      3
2   c          B      5
0   a          C      2
1   b          C      4
2   c          C      6
```

If you have multi-index columns:

```
>>> df.columns = [list('ABC'), list('DEF')]
>>> df
   A  B  C
   D  E  F
0   a  1  2
```

(continues on next page)

(continued from previous page)

1	b	3	4
2	c	5	6

```
>>> pd.melt(df, col_level=0, id_vars=['A'], value_vars=['B'])
   A variable  value
0  a          B      1
1  b          B      3
2  c          B      5
```

```
>>> pd.melt(df, id_vars=[('A', 'D')], value_vars=[('B', 'E')])
(A, D) variable_0 variable_1  value
0      a          B          E      1
1      b          B          E      3
2      c          B          E      5
```

pandas.pivot

`pandas.pivot(data, index=None, columns=None, values=None)`

Return reshaped DataFrame organized by given index / column values.

Reshape data (produce a “pivot” table) based on column values. Uses unique values from specified `index / columns` to form axes of the resulting DataFrame. This function does not support data aggregation, multiple values will result in a MultiIndex in the columns. See the [User Guide](#) for more on reshaping.

Parameters

`data` [DataFrame]

`index` [str or object or a list of str, optional] Column to use to make new frame’s index. If None, uses existing index.

Changed in version 1.1.0: Also accept list of index names.

`columns` [str or object or a list of str] Column to use to make new frame’s columns.

Changed in version 1.1.0: Also accept list of columns names.

`values` [str, object or a list of the previous, optional] Column(s) to use for populating new frame’s values. If not specified, all remaining columns will be used and the result will have hierarchically indexed columns.

Returns

`DataFrame` Returns reshaped DataFrame.

Raises

`ValueError`: When there are any `index, columns` combinations with multiple values.
`DataFrame.pivot_table` when you need to aggregate.

See also:

`DataFrame.pivot_table` Generalization of pivot that can handle duplicate values for one index/column pair.

`DataFrame.unstack` Pivot based on the index values instead of a column.

`wide_to_long` Wide panel to long format. Less flexible but more user-friendly than melt.

Notes

For finer-tuned control, see hierarchical indexing documentation along with the related stack/unstack methods. Reference [the user guide](#) for more examples.

Examples

```
>>> df = pd.DataFrame({'foo': ['one', 'one', 'one', 'two', 'two',
...                           'two'],
...                     'bar': ['A', 'B', 'C', 'A', 'B', 'C'],
...                     'baz': [1, 2, 3, 4, 5, 6],
...                     'zoo': ['x', 'y', 'z', 'q', 'w', 't']})
>>> df
   foo  bar  baz  zoo
0  one    A    1    x
1  one    B    2    y
2  one    C    3    z
3  two    A    4    q
4  two    B    5    w
5  two    C    6    t
```

```
>>> df.pivot(index='foo', columns='bar', values='baz')
bar  A  B  C
foo
one  1  2  3
two  4  5  6
```

```
>>> df.pivot(index='foo', columns='bar')['baz']
bar  A  B  C
foo
one  1  2  3
two  4  5  6
```

```
>>> df.pivot(index='foo', columns='bar', values=['baz', 'zoo'])
      baz      zoo
bar  A  B  C  A  B  C
foo
one  1  2  3  x  y  z
two  4  5  6  q  w  t
```

You could also assign a list of column names or a list of index names.

```
>>> df = pd.DataFrame({
...     "lev1": [1, 1, 1, 2, 2, 2],
...     "lev2": [1, 1, 2, 1, 1, 2],
...     "lev3": [1, 2, 1, 2, 1, 2],
...     "lev4": [1, 2, 3, 4, 5, 6],
...     "values": [0, 1, 2, 3, 4, 5]})
>>> df
   lev1  lev2  lev3  lev4  values
0     1     1     1     1      0
```

(continues on next page)

(continued from previous page)

1	1	1	2	2	1
2	1	2	1	3	2
3	2	1	2	4	3
4	2	1	1	5	4
5	2	2	2	6	5

```
>>> df.pivot(index="lev1", columns=["lev2", "lev3"], values="values")
lev2      1      2
lev3      1      2
lev1
1      0.0  1.0  2.0  NaN
2      4.0  3.0  NaN  5.0
```

```
>>> df.pivot(index=["lev1", "lev2"], columns=["lev3"], values="values")
          lev3      1      2
lev1  lev2
1      1  0.0  1.0
      2  2.0  NaN
2      1  4.0  3.0
      2  NaN  5.0
```

A ValueError is raised if there are any duplicates.

```
>>> df = pd.DataFrame({"foo": ['one', 'one', 'two', 'two'],
...                     "bar": ['A', 'A', 'B', 'C'],
...                     "baz": [1, 2, 3, 4]})

>>> df
   foo bar  baz
0  one    A    1
1  one    A    2
2  two    B    3
3  two    C    4
```

Notice that the first two rows are the same for our *index* and *columns* arguments.

```
>>> df.pivot(index='foo', columns='bar', values='baz')
Traceback (most recent call last):
...
ValueError: Index contains duplicate entries, cannot reshape
```

pandas.pivot_table

`pandas.pivot_table(data, values=None, index=None, columns=None, aggfunc='mean', fill_value=None, margins=False, dropna=True, margins_name='All', observed=False, sort=True)`

Create a spreadsheet-style pivot table as a DataFrame.

The levels in the pivot table will be stored in MultiIndex objects (hierarchical indexes) on the index and columns of the result DataFrame.

Parameters

`data` [DataFrame]

values [column to aggregate, optional]

index [column, Grouper, array, or list of the previous] If an array is passed, it must be the same length as the data. The list can contain any of the other types (except list). Keys to group by on the pivot table index. If an array is passed, it is being used as the same manner as column values.

columns [column, Grouper, array, or list of the previous] If an array is passed, it must be the same length as the data. The list can contain any of the other types (except list). Keys to group by on the pivot table column. If an array is passed, it is being used as the same manner as column values.

aggfunc [function, list of functions, dict, default numpy.mean] If list of functions passed, the resulting pivot table will have hierarchical columns whose top level are the function names (inferred from the function objects themselves) If dict is passed, the key is column to aggregate and value is function or list of functions.

fill_value [scalar, default None] Value to replace missing values with (in the resulting pivot table, after aggregation).

margins [bool, default False] Add all row / columns (e.g. for subtotal / grand totals).

dropna [bool, default True] Do not include columns whose entries are all NaN.

margins_name [str, default ‘All’] Name of the row / column that will contain the totals when margins is True.

observed [bool, default False] This only applies if any of the groupers are Categoricals. If True: only show observed values for categorical groupers. If False: show all values for categorical groupers.

Changed in version 0.25.0.

sort [bool, default True] Specifies if the result should be sorted.

New in version 1.3.0.

Returns

DataFrame An Excel style pivot table.

See also:

DataFrame.pivot Pivot without aggregation that can handle non-numeric data.

DataFrame.melt Unpivot a DataFrame from wide to long format, optionally leaving identifiers set.

wide_to_long Wide panel to long format. Less flexible but more user-friendly than melt.

Notes

Reference [the user guide](#) for more examples.

Examples

```
>>> df = pd.DataFrame({'A': ["foo", "foo", "foo", "foo", "foo",
...                           "bar", "bar", "bar", "bar"],
...                      'B': ["one", "one", "one", "two", "two",
...                           "one", "one", "two", "two"],
...                      'C': ["small", "large", "large", "small",
...                           "small", "large", "small", "small",
...                           "large"],
...                      'D': [1, 2, 2, 3, 3, 4, 5, 6, 7],
...                      'E': [2, 4, 5, 5, 6, 6, 8, 9, 9]})

>>> df
   A      B      C  D  E
0  foo    one  small  1  2
1  foo    one  large  2  4
2  foo    one  large  2  5
3  foo    two  small  3  5
4  foo    two  small  3  6
5  bar    one  large  4  6
6  bar    one  small  5  8
7  bar    two  small  6  9
8  bar    two  large  7  9
```

This first example aggregates values by taking the sum.

```
>>> table = pd.pivot_table(df, values='D', index=['A', 'B'],
...                           columns=['C'], aggfunc=np.sum)

>>> table
C      large  small
A   B
bar one     4.0    5.0
    two     7.0    6.0
foo one     4.0    1.0
    two     NaN    6.0
```

We can also fill missing values using the *fill_value* parameter.

```
>>> table = pd.pivot_table(df, values='D', index=['A', 'B'],
...                           columns=['C'], aggfunc=np.sum, fill_value=0)

>>> table
C      large  small
A   B
bar one     4     5
    two     7     6
foo one     4     1
    two     0     6
```

The next example aggregates by taking the mean across multiple columns.

```
>>> table = pd.pivot_table(df, values=['D', 'E'], index=['A', 'C'],
...                           aggfunc={'D': np.mean,
...                                     'E': np.mean})

>>> table
```

(continues on next page)

(continued from previous page)

		D	E
A	C		
bar	large	5.500000	7.500000
	small	5.500000	8.500000
foo	large	2.000000	4.500000
	small	2.333333	4.333333

We can also calculate multiple types of aggregations for any given value column.

```
>>> table = pd.pivot_table(df, values=['D', 'E'], index=['A', 'C'],
...                         aggfunc={'D': np.mean,
...                                   'E': [min, max, np.mean]})

>>> table
      D   E
      mean max    mean  min
A   C
bar large  5.500000  9  7.500000  6
     small  5.500000  9  8.500000  8
foo large  2.000000  5  4.500000  4
     small  2.333333  6  4.333333  2
```

pandas.crosstab

`pandas.crosstab(index, columns, values=None, rownames=None, colnames=None, aggfunc=None, margins=False, margins_name='All', dropna=True, normalize=False)`

Compute a simple cross tabulation of two (or more) factors. By default computes a frequency table of the factors unless an array of values and an aggregation function are passed.

Parameters

index [array-like, Series, or list of arrays/Series] Values to group by in the rows.

columns [array-like, Series, or list of arrays/Series] Values to group by in the columns.

values [array-like, optional] Array of values to aggregate according to the factors. Requires `aggfunc` be specified.

rownames [sequence, default None] If passed, must match number of row arrays passed.

colnames [sequence, default None] If passed, must match number of column arrays passed.

aggfunc [function, optional] If specified, requires `values` be specified as well.

margins [bool, default False] Add row/column margins (subtotals).

margins_name [str, default ‘All’] Name of the row/column that will contain the totals when `margins` is True.

dropna [bool, default True] Do not include columns whose entries are all NaN.

normalize [bool, {‘all’, ‘index’, ‘columns’}, or {0,1}, default False] Normalize by dividing all values by the sum of values.

- If passed ‘all’ or `True`, will normalize over all values.
- If passed ‘index’ will normalize over each row.
- If passed ‘columns’ will normalize over each column.

- If margins is *True*, will also normalize margin values.

Returns

DataFrame Cross tabulation of the data.

See also:

DataFrame.pivot Reshape data based on column values.

pivot_table Create a pivot table as a DataFrame.

Notes

Any Series passed will have their name attributes used unless row or column names for the cross-tabulation are specified.

Any input passed containing Categorical data will have **all** of its categories included in the cross-tabulation, even if the actual data does not contain any instances of a particular category.

In the event that there aren't overlapping indexes an empty DataFrame will be returned.

Reference *the user guide* for more examples.

Examples

```
>>> a = np.array(["foo", "foo", "foo", "foo", "bar", "bar",
...                 "bar", "bar", "foo", "foo", "foo"], dtype=object)
>>> b = np.array(["one", "one", "one", "two", "one", "one",
...                 "one", "two", "two", "two", "one"], dtype=object)
>>> c = np.array(["dull", "dull", "shiny", "dull", "dull", "shiny",
...                 "shiny", "dull", "shiny", "shiny", "shiny"],
...                 dtype=object)
>>> pd.crosstab(a, [b, c], rownames=['a'], colnames=['b', 'c'])
b   one      two
c  dull shiny dull shiny
a
bar    1    2    1    0
foo    2    2    1    2
```

Here ‘c’ and ‘f’ are not represented in the data and will not be shown in the output because dropna is True by default. Set dropna=False to preserve categories with no data.

```
>>> foo = pd.Categorical(['a', 'b'], categories=['a', 'b', 'c'])
>>> bar = pd.Categorical(['d', 'e'], categories=['d', 'e', 'f'])
>>> pd.crosstab(foo, bar)
col_0  d  e
row_0
a      1  0
b      0  1
>>> pd.crosstab(foo, bar, dropna=False)
col_0  d  e  f
row_0
a      1  0  0
b      0  1  0
c      0  0  0
```

pandas.cut

当需要将数据值分割和排序到存储箱中时，请使用“剪切”。此函数对于从连续变量到分类变量。例如，`cut`可以将年龄转换为年龄范围的组。支持装箱到相同数量的箱子或预先指定的箱子阵列中。
有点类似给成绩设定优良中差

`pandas.cut(x, bins, right=True, labels=None, retbins=False, precision=3, include_lowest=False, duplicates='raise', ordered=True)`

Bin values into discrete intervals.

Use `cut` when you need to segment and sort data values into bins. This function is also useful for going from a continuous variable to a categorical variable. For example, `cut` could convert ages to groups of age ranges. Supports binning into an equal number of bins, or a pre-specified array of bins.

Parameters

x [array-like] The input array to be binned. Must be 1-dimensional.

bins [int, sequence of scalars, or IntervalIndex] The criteria to bin by.

- int : Defines the number of equal-width bins in the range of *x*. The range of *x* is extended by .1% on each side to include the minimum and maximum values of *x*.
- sequence of scalars : Defines the bin edges allowing for non-uniform width. No extension of the range of *x* is done.
- IntervalIndex : Defines the exact bins to be used. Note that IntervalIndex for *bins* must be non-overlapping.

right [bool, default True] Indicates whether *bins* includes the rightmost edge or not. If `right == True` (the default), then the *bins* [1, 2, 3, 4] indicate (1,2], (2,3], (3,4]. This argument is ignored when *bins* is an IntervalIndex.

labels [array or False, default None] Specifies the labels for the returned bins. Must be the same length as the resulting bins. If False, returns only integer indicators of the bins. This affects the type of the output container (see below). This argument is ignored when *bins* is an IntervalIndex. If True, raises an error. When `ordered=False`, labels must be provided.

retbins [bool, default False] Whether to return the bins or not. Useful when *bins* is provided as a scalar.

precision [int, default 3] The precision at which to store and display the bins labels.

include_lowest [bool, default False] Whether the first interval should be left-inclusive or not.

duplicates [{default ‘raise’, ‘drop’}, optional] If bin edges are not unique, raise ValueError or drop non-uniques.

ordered [bool, default True] Whether the labels are ordered or not. Applies to returned types Categorical and Series (with Categorical dtype). If True, the resulting categorical will be ordered. If False, the resulting categorical will be unordered (labels must be provided).

New in version 1.1.0.

Returns

out [Categorical, Series, or ndarray] An array-like object representing the respective bin for each value of *x*. The type depends on the value of *labels*.

- None (default) : returns a Series for Series *x* or a Categorical for all other inputs. The values stored within are Interval dtype.
- sequence of scalars : returns a Series for Series *x* or a Categorical for all other inputs. The values stored within are whatever the type in the sequence is.
- False : returns an ndarray of integers.

bins [numpy.ndarray or IntervalIndex.] The computed or specified bins. Only returned when *retbins=True*. For scalar or sequence *bins*, this is an ndarray with the computed bins. If set *duplicates=drop*, *bins* will drop non-unique bin. For an IntervalIndex *bins*, this is equal to *bins*.

See also:

[qcut](#) Discretize variable into equal-sized buckets based on rank or based on sample quantiles.

[Categorical](#) Array type for storing data that come from a fixed set of values.

[Series](#) One-dimensional array with axis labels (including time series).

[IntervalIndex](#) Immutable Index implementing an ordered, sliceable set.

Notes

Any NA values will be NA in the result. Out of bounds values will be NA in the resulting Series or Categorical object.

Reference [the user guide](#) for more examples.

Examples

Discretize into three equal-sized bins.

```
>>> pd.cut(np.array([1, 7, 5, 4, 6, 3]), 3)
...
[(-0.994, 3.0], (5.0, 7.0], (3.0, 5.0], (3.0, 5.0], (5.0, 7.0], ...
Categories (3, interval[float64, right]): [(-0.994, 3.0] < (3.0, 5.0] ...
```

```
>>> pd.cut(np.array([1, 7, 5, 4, 6, 3]), 3, retbins=True)
...
[(-0.994, 3.0], (5.0, 7.0], (3.0, 5.0], (3.0, 5.0], (5.0, 7.0], ...
Categories (3, interval[float64, right]): [(-0.994, 3.0] < (3.0, 5.0] ...
array([-0.994, 3.0, 5.0, 7.0])]
```

Discovers the same bins, but assign them specific labels. Notice that the returned Categorical's categories are *labels* and is ordered.

```
>>> pd.cut(np.array([1, 7, 5, 4, 6, 3]),
...         3, labels=["bad", "medium", "good"])
['bad', 'good', 'medium', 'medium', 'good', 'bad']
Categories (3, object): ['bad' < 'medium' < 'good']
```

ordered=False will result in unordered categories when labels are passed. This parameter can be used to allow non-unique labels:

```
>>> pd.cut(np.array([1, 7, 5, 4, 6, 3]), 3,
...         labels=["B", "A", "B"], ordered=False)
['B', 'B', 'A', 'A', 'B', 'B']
Categories (2, object): ['A', 'B']
```

labels=False implies you just want the bins back.

```
>>> pd.cut([0, 1, 1, 2], bins=4, labels=False)
array([0, 1, 1, 3])
```

Passing a Series as an input returns a Series with categorical dtype:

```
>>> s = pd.Series(np.array([2, 4, 6, 8, 10]),
...                 index=['a', 'b', 'c', 'd', 'e'])
>>> pd.cut(s, 3)
...
a    (1.992, 4.667]
b    (1.992, 4.667]
c    (4.667, 7.333]
d    (7.333, 10.0]
e    (7.333, 10.0]
dtype: category
Categories (3, interval[float64, right]): [(1.992, 4.667] < (4.667, ...]
```

Passing a Series as an input returns a Series with mapping value. It is used to map numerically to intervals based on bins.

```
>>> s = pd.Series(np.array([2, 4, 6, 8, 10]),
...                 index=['a', 'b', 'c', 'd', 'e'])
>>> pd.cut(s, [0, 2, 4, 6, 8, 10], labels=False, retbins=True, right=False)
...
(a    1.0
 b    2.0
 c    3.0
 d    4.0
 e    NaN
dtype: float64,
array([ 0,  2,  4,  6,  8, 10]))
```

Use *drop* optional when bins is not unique

```
>>> pd.cut(s, [0, 2, 4, 6, 10, 10], labels=False, retbins=True,
...           right=False, duplicates='drop')
...
(a    1.0
 b    2.0
 c    3.0
 d    3.0
 e    NaN
dtype: float64,
array([ 0,  2,  4,  6, 10]))
```

Passing an IntervalIndex for *bins* results in those categories exactly. Notice that values not covered by the IntervalIndex are set to NaN. 0 is to the left of the first bin (which is closed on the right), and 1.5 falls between two bins.

```
>>> bins = pd.IntervalIndex.from_tuples([(0, 1), (2, 3), (4, 5)])
>>> pd.cut([0, 0.5, 1.5, 2.5, 4.5], bins)
[NaN, (0.0, 1.0], NaN, (2.0, 3.0], (4.0, 5.0]]
Categories (3, interval[int64, right]): [(0, 1] < (2, 3] < (4, 5]]
```

pandas.qcut

`pandas.qcut(x, q, labels=None, retbins=False, precision=3, duplicates='raise')`

Quantile-based discretization function.

Discretize variable into equal-sized buckets based on rank or based on sample quantiles. For example 1000 values for 10 quantiles would produce a Categorical object indicating quantile membership for each data point.

Parameters

x [1d ndarray or Series]

q [int or list-like of float] Number of quantiles. 10 for deciles, 4 for quartiles, etc. Alternately array of quantiles, e.g. [0, .25, .5, .75, 1.] for quartiles.

labels [array or False, default None] Used as labels for the resulting bins. Must be of the same length as the resulting bins. If False, return only integer indicators of the bins. If True, raises an error.

retbins [bool, optional] Whether to return the (bins, labels) or not. Can be useful if bins is given as a scalar.

precision [int, optional] The precision at which to store and display the bins labels.

duplicates [{default ‘raise’, ‘drop’}, optional] If bin edges are not unique, raise ValueError or drop non-uniques.

Returns

out [Categorical or Series or array of integers if labels is False] The return type (Categorical or Series) depends on the input: a Series of type category if input is a Series else Categorical. Bins are represented as categories when categorical data is returned.

bins [ndarray of floats] Returned only if *retbins* is True.

Notes

Out of bounds values will be NA in the resulting Categorical object

Examples

```
>>> pd.qcut(range(5), 4)
...
[(-0.001, 1.0], (-0.001, 1.0], (1.0, 2.0], (2.0, 3.0], (3.0, 4.0]]
Categories (4, interval[float64, right]): [(-0.001, 1.0] < (1.0, 2.0] ...
```

```
>>> pd.qcut(range(5), 3, labels=["good", "medium", "bad"])
...
[good, good, medium, bad, bad]
Categories (3, object): [good < medium < bad]
```

```
>>> pd.qcut(range(5), 4, labels=False)
array([0, 0, 1, 2, 3])
```

pandas.merge

```
pandas.merge(left, right, how='inner', on=None, left_on=None, right_on=None, left_index=False,  
            right_index=False, sort=False, suffixes=('_x', '_y'), copy=True, indicator=False, validate=None)
```

Merge DataFrame or named Series objects with a database-style join.

A named Series object is treated as a DataFrame with a single named column.

The join is done on columns or indexes. If joining columns on columns, the DataFrame indexes *will be ignored*. Otherwise if joining indexes on indexes or indexes on a column or columns, the index will be passed on. When performing a cross merge, no column specifications to merge on are allowed.

Warning: If both key columns contain rows where the key is a null value, those rows will be matched against each other. This is different from usual SQL join behaviour and can lead to unexpected results.

Parameters

left [DataFrame]

right [DataFrame or named Series] Object to merge with.

how [{‘left’, ‘right’, ‘outer’, ‘inner’, ‘cross’}, default ‘inner’] Type of merge to be performed.

- left: use only keys from left frame, similar to a SQL left outer join; preserve key order.
- right: use only keys from right frame, similar to a SQL right outer join; preserve key order.
- outer: use union of keys from both frames, similar to a SQL full outer join; sort keys lexicographically.
- inner: use intersection of keys from both frames, similar to a SQL inner join; preserve the order of the left keys.
- cross: creates the cartesian product from both frames, preserves the order of the left keys.

New in version 1.2.0.

on [label or list] Column or index level names to join on. These must be found in both DataFrames. If *on* is None and not merging on indexes then this defaults to the intersection of the columns in both DataFrames.

left_on [label or list, or array-like] Column or index level names to join on in the left DataFrame. Can also be an array or list of arrays of the length of the left DataFrame. These arrays are treated as if they are columns.

right_on [label or list, or array-like] Column or index level names to join on in the right DataFrame. Can also be an array or list of arrays of the length of the right DataFrame. These arrays are treated as if they are columns.

left_index [bool, default False] Use the index from the left DataFrame as the join key(s). If it is a MultiIndex, the number of keys in the other DataFrame (either the index or a number of columns) must match the number of levels.

right_index [bool, default False] Use the index from the right DataFrame as the join key. Same caveats as *left_index*.

sort [bool, default False] Sort the join keys lexicographically in the result DataFrame. If False, the order of the join keys depends on the join type (how keyword).

suffixes [list-like, default is (“_x”, “_y”)] A length-2 sequence where each element is optionally a string indicating the suffix to add to overlapping column names in *left* and *right* respectively. Pass a value of *None* instead of a string to indicate that the column name from *left* or *right* should be left as-is, with no suffix. At least one of the values must not be *None*.

copy [bool, default True] If False, avoid copy if possible.

indicator [bool or str, default False] If True, adds a column to the output DataFrame called “_merge” with information on the source of each row. The column can be given a different name by providing a string argument. The column will have a Categorical type with the value of “left_only” for observations whose merge key only appears in the left DataFrame, “right_only” for observations whose merge key only appears in the right DataFrame, and “both” if the observation’s merge key is found in both DataFrames.

validate [str, optional] If specified, checks if merge is of specified type.

- “one_to_one” or “1:1”: check if merge keys are unique in both left and right datasets.
- “one_to_many” or “1:m”: check if merge keys are unique in left dataset.
- “many_to_one” or “m:1”: check if merge keys are unique in right dataset.
- “many_to_many” or “m:m”: allowed, but does not result in checks.

Returns

DataFrame A DataFrame of the two merged objects.

See also:

[merge_ordered](#) Merge with optional filling/interpolation.

[merge_asof](#) Merge on nearest keys.

[DataFrame.join](#) Similar method using indices.

Notes

Support for specifying index levels as the *on*, *left_on*, and *right_on* parameters was added in version 0.23.0
Support for merging named Series objects was added in version 0.24.0

Examples

```
>>> df1 = pd.DataFrame({'lkey': ['foo', 'bar', 'baz', 'foo'],
...                      'value': [1, 2, 3, 5]})
>>> df2 = pd.DataFrame({'rkey': ['foo', 'bar', 'baz', 'foo'],
...                      'value': [5, 6, 7, 8]})
>>> df1
   lkey  value
0    foo      1
1    bar      2
2    baz      3
3    foo      5
>>> df2
   rkey  value
0    foo      5
```

(continues on next page)

(continued from previous page)

1	bar	6
2	baz	7
3	foo	8

Merge df1 and df2 on the lkey and rkey columns. The value columns have the default suffixes, _x and _y, appended.

```
>>> df1.merge(df2, left_on='lkey', right_on='rkey')
   lkey  value_x  rkey  value_y
0  foo        1  foo        5
1  foo        1  foo        8
2  foo        5  foo        5
3  foo        5  foo        8
4  bar        2  bar        6
5  baz        3  baz        7
```

Merge DataFrames df1 and df2 with specified left and right suffixes appended to any overlapping columns.

```
>>> df1.merge(df2, left_on='lkey', right_on='rkey',
...             suffixes=('_left', '_right'))
   lkey  value_left  rkey  value_right
0  foo            1  foo            5
1  foo            1  foo            8
2  foo            5  foo            5
3  foo            5  foo            8
4  bar            2  bar            6
5  baz            3  baz            7
```

Merge DataFrames df1 and df2, but raise an exception if the DataFrames have any overlapping columns.

```
>>> df1.merge(df2, left_on='lkey', right_on='rkey', suffixes=(False, False))
Traceback (most recent call last):
...
ValueError: columns overlap but no suffix specified:
Index(['value'], dtype='object')
```

```
>>> df1 = pd.DataFrame({'a': ['foo', 'bar'], 'b': [1, 2]})
>>> df2 = pd.DataFrame({'a': ['foo', 'baz'], 'c': [3, 4]})
>>> df1
   a  b
0  foo  1
1  bar  2
>>> df2
   a  c
0  foo  3
1  baz  4
```

```
>>> df1.merge(df2, how='inner', on='a')
   a  b  c
0  foo  1  3
```

```
>>> df1.merge(df2, how='left', on='a')
      a   b   c
0   foo   1  3.0
1   bar   2   NaN
```

```
>>> df1 = pd.DataFrame({'left': ['foo', 'bar']})
>>> df2 = pd.DataFrame({'right': [7, 8]})
```

	left	right
0	foo	7
1	bar	8

```
>>> df1.merge(df2, how='cross')
      left   right
0     foo       7
1     foo       8
2     bar       7
3     bar       8
```

pandas.merge_ordered

`pandas.merge_ordered(left, right, on=None, left_on=None, right_on=None, left_by=None, right_by=None, fill_method=None, suffixes=('_x', '_y'), how='outer')`

Perform a merge for ordered data with optional filling/interpolation. 使用可选填充/插值对有序数据执行合并。

Designed for ordered data like time series data. Optionally perform group-wise merge (see examples).

Parameters

left [DataFrame]

right [DataFrame]

on [label or list] Field names to join on. Must be found in both DataFrames.

left_on [label or list, or array-like] Field names to join on in left DataFrame. Can be a vector or list of vectors of the length of the DataFrame to use a particular vector as the join key instead of columns.

right_on [label or list, or array-like] Field names to join on in right DataFrame or vector/list of vectors per left_on docs.

left_by [column name or list of column names] Group left DataFrame by group columns and merge piece by piece with right DataFrame.

right_by [column name or list of column names] Group right DataFrame by group columns and merge piece by piece with left DataFrame.

fill_method [{‘ffill’, None}, default None] Interpolation method for data.

suffixes [list-like, default is (“_x”, “_y”)] A length-2 sequence where each element is optionally a string indicating the suffix to add to overlapping column names in *left* and *right* respectively. Pass a value of *None* instead of a string to indicate that the column name

from *left* or *right* should be left as-is, with no suffix. At least one of the values must not be None.

Changed in version 0.25.0.

how [{‘left’, ‘right’, ‘outer’, ‘inner’}], default ‘outer’

- left: use only keys from left frame (SQL: left outer join)
- right: use only keys from right frame (SQL: right outer join)
- outer: use union of keys from both frames (SQL: full outer join)
- inner: use intersection of keys from both frames (SQL: inner join).

Returns

DataFrame The merged DataFrame output type will be same as ‘left’, if it is a subclass of DataFrame.

See also:

[merge](#) Merge with a database-style join.

[merge_asof](#) Merge on nearest keys.

Examples

```
>>> df1 = pd.DataFrame(  
...     {  
...         "key": ["a", "c", "e", "a", "c", "e"],  
...         "lvalue": [1, 2, 3, 1, 2, 3],  
...         "group": ["a", "a", "a", "b", "b", "b"]  
...     }  
... )  
>>> df1  
    key  lvalue group  
0   a      1     a  
1   c      2     a  
2   e      3     a  
3   a      1     b  
4   c      2     b  
5   e      3     b
```

```
>>> df2 = pd.DataFrame({"key": ["b", "c", "d"], "rvalue": [1, 2, 3]})  
>>> df2  
    key  rvalue  
0   b      1  
1   c      2  
2   d      3
```

```
>>> merge_ordered(df1, df2, fill_method="ffill", left_by="group")  
    key  lvalue group  rvalue  
0   a      1     a    NaN  
1   b      1     a    1.0  
2   c      2     a    2.0  
3   d      2     a    3.0
```

(continues on next page)

(continued from previous page)

4	e	3	a	3.0
5	a	1	b	NaN
6	b	1	b	1.0
7	c	2	b	2.0
8	d	2	b	3.0
9	e	3	b	3.0

pandas.merge_asof

```
pandas.merge_asof(left, right, on=None, left_on=None, right_on=None, left_index=False, right_index=False,
                  by=None, left_by=None, right_by=None, suffixes=('_x', '_y'), tolerance=None,
                  allow_exact_matches=True, direction='backward')
```

Perform a merge by key distance.

This is similar to a left-join except that we match on nearest key rather than equal keys. Both DataFrames must be sorted by the key.

这类似于左连接，只是我们在最近的关键点而不是相等的关键点上进行匹配。两个数据帧都必须按键排序。

For each row in the left DataFrame:

- A “backward” search selects the last row in the right DataFrame whose ‘on’ key is less than or equal to the left’s key.
- A “forward” search selects the first row in the right DataFrame whose ‘on’ key is greater than or equal to the left’s key.
- A “nearest” search selects the row in the right DataFrame whose ‘on’ key is closest in absolute distance to the left’s key.

The default is “backward” and is compatible in versions below 0.20.0. The direction parameter was added in version 0.20.0 and introduces “forward” and “nearest”.

Optionally match on equivalent keys with ‘by’ before searching with ‘on’.

Parameters

left [DataFrame or named Series]

right [DataFrame or named Series]

on [label] Field name to join on. Must be found in both DataFrames. The data MUST be ordered. Furthermore this must be a numeric column, such as datetimelike, integer, or float. On or left_on/right_on must be given.

left_on [label] Field name to join on in left DataFrame.

right_on [label] Field name to join on in right DataFrame.

left_index [bool] Use the index of the left DataFrame as the join key.

right_index [bool] Use the index of the right DataFrame as the join key.

by [column name or list of column names] Match on these columns before performing merge operation.

left_by [column name] Field names to match on in the left DataFrame.

right_by [column name] Field names to match on in the right DataFrame.

suffixes [2-length sequence (tuple, list, ...)] Suffix to apply to overlapping column names in the left and right side, respectively.

tolerance [int or Timedelta, optional, default None] Select asof tolerance within this range; must be compatible with the merge index.

allow_exact_matches [bool, default True]

- If True, allow matching with the same ‘on’ value (i.e. less-than-or-equal-to / greater-than-or-equal-to)
- If False, don’t match the same ‘on’ value (i.e., strictly less-than / strictly greater-than).

direction ['backward' (default), 'forward', or 'nearest'] Whether to search for prior, subsequent, or closest matches.

Returns

merged [DataFrame]

See also:

[merge](#) Merge with a database-style join.

[merge_ordered](#) Merge with optional filling/interpolation.

Examples

```
>>> left = pd.DataFrame({"a": [1, 5, 10], "left_val": ["a", "b", "c"]})  
>>> left  
   a    left_val  
0  1        a  
1  5        b  
2  10       c
```

```
>>> right = pd.DataFrame({"a": [1, 2, 3, 6, 7], "right_val": [1, 2, 3, 6, 7]})  
>>> right  
   a    right_val  
0  1        1  
1  2        2  
2  3        3  
3  6        6  
4  7        7
```

```
>>> pd.merge_asof(left, right, on="a")  
   a    left_val    right_val  
0  1        a        1  
1  5        b        3  
2  10       c        7
```

```
>>> pd.merge_asof(left, right, on="a", allow_exact_matches=False)  
   a    left_val    right_val  
0  1        a        NaN  
1  5        b        3.0  
2  10       c        7.0
```

```
>>> pd.merge_asof(left, right, on="a", direction="forward")  
   a    left_val    right_val
```

(continues on next page)

(continued from previous page)

0	1	a	1.0
1	5	b	6.0
2	10	c	NaN

```
>>> pd.merge_asof(left, right, on="a", direction="nearest")
   a left_val  right_val
0  1         a          1
1  5         b          6
2 10        c          7
```

We can use indexed DataFrames as well.

```
>>> left = pd.DataFrame({"left_val": ["a", "b", "c"]}, index=[1, 5, 10])
>>> left
   left_val
1         a
5         b
10        c
```

```
>>> right = pd.DataFrame({"right_val": [1, 2, 3, 6, 7]}, index=[1, 2, 3, 6, 7])
>>> right
   right_val
1            1
2            2
3            3
6            6
7            7
```

```
>>> pd.merge_asof(left, right, left_index=True, right_index=True)
   left_val  right_val
1         a          1
5         b          3
10        c          7
```

Here is a real-world times-series example

```
>>> quotes = pd.DataFrame(
...     {
...         "time": [
...             pd.Timestamp("2016-05-25 13:30:00.023"),
...             pd.Timestamp("2016-05-25 13:30:00.023"),
...             pd.Timestamp("2016-05-25 13:30:00.030"),

```

pandas.concat

`pandas.concat(objs, axis=0, join='outer', ignore_index=False, keys=None, levels=None, names=None, verify_integrity=False, sort=False, copy=True)`

Concatenate pandas objects along a particular axis with optional set logic along the other axes.

Can also add a layer of hierarchical indexing on the concatenation axis, which may be useful if the labels are the same (or overlapping) on the passed axis number.

Parameters

objs [a sequence or mapping of Series or DataFrame objects] If a mapping is passed, the sorted keys will be used as the *keys* argument, unless it is passed, in which case the values will be selected (see below). Any None objects will be dropped silently unless they are all None in which case a ValueError will be raised.

axis [{0/'index', 1/'columns'}, default 0] The axis to concatenate along.

join [{‘inner’, ‘outer’}, default ‘outer’] How to handle indexes on other axis (or axes).

ignore_index [bool, default False] If True, do not use the index values along the concatenation axis. The resulting axis will be labeled 0, ..., n - 1. This is useful if you are concatenating objects where the concatenation axis does not have meaningful indexing information. Note the index values on the other axes are still respected in the join.

keys [sequence, default None] If multiple levels passed, should contain tuples. Construct hierarchical index using the passed keys as the outermost level.

levels [list of sequences, default None] Specific levels (unique values) to use for constructing a MultiIndex. Otherwise they will be inferred from the keys.

names [list, default None] Names for the levels in the resulting hierarchical index.

verify_integrity [bool, default False] Check whether the new concatenated axis contains duplicates. This can be very expensive relative to the actual data concatenation.

sort [bool, default False] Sort non-concatenation axis if it is not already aligned when *join* is ‘outer’. This has no effect when *join*=‘inner’, which already preserves the order of the non-concatenation axis.

Changed in version 1.0.0: Changed to not sort by default.

copy [bool, default True] If False, do not copy data unnecessarily.

Returns

object, type of objs When concatenating all Series along the index (axis=0), a Series is returned. When objs contains at least one DataFrame, a DataFrame is returned. When concatenating along the columns (axis=1), a DataFrame is returned.

See also:

[**Series.append**](#) Concatenate Series.

[**DataFrame.append**](#) Concatenate DataFrames.

[**DataFrame.join**](#) Join DataFrames using indexes.

[**DataFrame.merge**](#) Merge DataFrames by indexes or columns.

Notes

The keys, levels, and names arguments are all optional.

A walkthrough of how this method fits in with other tools for combining pandas objects can be found [here](#).

Examples

Combine two Series.

```
>>> s1 = pd.Series(['a', 'b'])
>>> s2 = pd.Series(['c', 'd'])
>>> pd.concat([s1, s2])
0    a
1    b
0    c
1    d
dtype: object
```

Clear the existing index and reset it in the result by setting the `ignore_index` option to True.

```
>>> pd.concat([s1, s2], ignore_index=True)
0    a
1    b
2    c
3    d
dtype: object
```

Add a hierarchical index at the outermost level of the data with the `keys` option.

```
>>> pd.concat([s1, s2], keys=['s1', 's2'])
s1    0    a
      1    b
s2    0    c
      1    d
dtype: object
```

Label the index keys you create with the `names` option.

```
>>> pd.concat([s1, s2], keys=['s1', 's2'],
...             names=['Series name', 'Row ID'])
Series name  Row ID
s1            0      a
                1      b
s2            0      c
                1      d
dtype: object
```

Combine two DataFrame objects with identical columns.

```
>>> df1 = pd.DataFrame([[['a', 1], ['b', 2]],
...                      columns=['letter', 'number']])
>>> df1
   letter  number
0       a      1
1       b      2
>>> df2 = pd.DataFrame([[['c', 3], ['d', 4]],
...                      columns=['letter', 'number']])
>>> df2
   letter  number
0       c      3
1       d      4
>>> pd.concat([df1, df2])
   letter  number
0       a      1
1       b      2
0       c      3
1       d      4
```

Combine DataFrame objects with overlapping columns and return everything. Columns outside the intersection will be filled with NaN values.

```
>>> df3 = pd.DataFrame([[['c', 3, 'cat'], ['d', 4, 'dog']],
...                      columns=['letter', 'number', 'animal']])
>>> df3
   letter  number  animal
0       c      3    cat
1       d      4    dog
>>> pd.concat([df1, df3], sort=False)
   letter  number  animal
0       a      1    NaN
1       b      2    NaN
```

(continues on next page)

(continued from previous page)

0	c	3	cat
1	d	4	dog

Combine DataFrame objects with overlapping columns and return only those that are shared by passing `inner` to the `join` keyword argument.

```
>>> pd.concat([df1, df3], join="inner")
   letter  number
0      a        1
1      b        2
0      c        3
1      d        4
```

Combine DataFrame objects horizontally along the x axis by passing in `axis=1`.

```
>>> df4 = pd.DataFrame([[ 'bird', 'polly'], [ 'monkey', 'george']],
...                      columns=[ 'animal', 'name'])
>>> pd.concat([df1, df4], axis=1)
   letter  number  animal    name
0      a        1    bird   polly
1      b        2  monkey  george
```

Prevent the result from including duplicate index values with the `verify_integrity` option.

```
>>> df5 = pd.DataFrame([1], index=[ 'a'])
>>> df5
   0
a  1
>>> df6 = pd.DataFrame([2], index=[ 'a'])
>>> df6
   0
a  2
>>> pd.concat([df5, df6], verify_integrity=True)
Traceback (most recent call last):
...
ValueError: Indexes have overlapping values: ['a']
```

pandas.get_dummies

`pandas.get_dummies(data, prefix=None, prefix_sep='_', dummy_na=False, columns=None, sparse=False, drop_first=False, dtype=None)`

Convert categorical variable into dummy/indicator variables.

Parameters

`data` [array-like, Series, or DataFrame] Data of which to get dummy indicators.

`prefix` [str, list of str, or dict of str, default None] String to append DataFrame column names.

Pass a list with length equal to the number of columns when calling `get_dummies` on a DataFrame. Alternatively, `prefix` can be a dictionary mapping column names to prefixes.

`prefix_sep` [str, default '_'] If appending prefix, separator/delimiter to use. Or pass a list or dictionary as with `prefix`.

`dummy_na` [bool, default False] Add a column to indicate NaNs, if False NaNs are ignored.

columns [list-like, default None] Column names in the DataFrame to be encoded. If *columns* is None then all the columns with *object* or *category* dtype will be converted.

sparse [bool, default False] Whether the dummy-encoded columns should be backed by a *SparseArray* (True) or a regular NumPy array (False).

drop_first [bool, default False] Whether to get k-1 dummies out of k categorical levels by removing the first level.

dtype [dtype, default np.uint8] Data type for new columns. Only a single dtype is allowed.

Returns

DataFrame Dummy-coded data.

See also:

Series.str.get_dummies Convert Series to dummy codes.

Notes

Reference *the user guide* for more examples.

Examples

```
>>> s = pd.Series(list('abca'))
```

```
>>> pd.get_dummies(s)
   a   b   c
0  1   0   0
1  0   1   0
2  0   0   1
3  1   0   0
```

```
>>> s1 = ['a', 'b', np.nan]
```

```
>>> pd.get_dummies(s1)
   a   b
0  1   0
1  0   1
2  0   0
```

```
>>> pd.get_dummies(s1, dummy_na=True)
   a   b   NaN
0  1   0     0
1  0   1     0
2  0   0     1
```

```
>>> df = pd.DataFrame({'A': ['a', 'b', 'a'], 'B': ['b', 'a', 'c'],
...                      'C': [1, 2, 3]})
```

```
>>> pd.get_dummies(df, prefix=['col1', 'col2'])
   C  col1_a  col1_b  col2_a  col2_b  col2_c
0  1      1      0      0      1      0
1  2      0      1      1      0      0
2  3      1      0      0      0      1
```

```
>>> pd.get_dummies(pd.Series(list('abcaa')))
   a  b  c
0  1  0  0
1  0  1  0
2  0  0  1
3  1  0  0
4  1  0  0
```

```
>>> pd.get_dummies(pd.Series(list('abcaa')), drop_first=True)
   b  c
0  0  0
1  1  0
2  0  1
3  0  0
4  0  0
```

```
>>> pd.get_dummies(pd.Series(list('abc')), dtype=float)
   a    b    c
0  1.0  0.0  0.0
1  0.0  1.0  0.0
2  0.0  0.0  1.0
```

pandas.factorize

`pandas.factorize(values, sort=False, na_sentinel=-1, size_hint=None)`

Encode the object as an enumerated type or categorical variable.

This method is useful for obtaining a numeric representation of an array when all that matters is identifying distinct values. `factorize` is available as both a top-level function `pandas.factorize()`, and as a method `Series.factorize()` and `Index.factorize()`.

Parameters

values [sequence] A 1-D sequence. Sequences that aren't pandas objects are coerced to ndarrays before factorization.

sort [bool, default False] Sort *uniques* and shuffle *codes* to maintain the relationship.

na_sentinel [int or None, default -1] Value to mark “not found”. If None, will not drop the NaN from the uniques of the values.

Changed in version 1.1.2.

size_hint [int, optional] Hint to the hashtable sizer.

Returns

codes [ndarray] An integer ndarray that's an indexer into *uniques*. `uniques.take(codes)` will have the same values as *values*.

uniques [ndarray, Index, or Categorical] The unique valid values. When *values* is Categorical, *uniques* is a Categorical. When *values* is some other pandas object, an *Index* is returned. Otherwise, a 1-D ndarray is returned.

Note: Even if there's a missing value in *values*, *uniques* will *not* contain an entry for it.

See also:

[cut](#) Discretize continuous-valued array.

[unique](#) Find the unique value in an array.

Notes

Reference [the user guide](#) for more examples.

Examples

These examples all show factorize as a top-level method like `pd.factorize(values)`. The results are identical for methods like `Series.factorize()`.

```
>>> codes, uniques = pd.factorize(['b', 'b', 'a', 'c', 'b'])
>>> codes
array([0, 0, 1, 2, 0]...)
>>> uniques
array(['b', 'a', 'c'], dtype=object)
```

With `sort=True`, the *uniques* will be sorted, and *codes* will be shuffled so that the relationship is maintained.

```
>>> codes, uniques = pd.factorize(['b', 'b', 'a', 'c', 'b'], sort=True)
>>> codes
array([1, 1, 0, 2, 1]...)
>>> uniques
array(['a', 'b', 'c'], dtype=object)
```

Missing values are indicated in *codes* with *na_sentinel* (-1 by default). Note that missing values are never included in *uniques*.

```
>>> codes, uniques = pd.factorize(['b', None, 'a', 'c', 'b'])
>>> codes
array([ 0, -1,  1,  2,  0]...)
>>> uniques
array(['b', 'a', 'c'], dtype=object)
```

Thus far, we've only factorized lists (which are internally coerced to NumPy arrays). When factorizing pandas objects, the type of *uniques* will differ. For Categoricals, a *Categorical* is returned.

```
>>> cat = pd.Categorical(['a', 'a', 'c'], categories=['a', 'b', 'c'])
>>> codes, uniques = pd.factorize(cat)
>>> codes
array([0, 0, 1]...)
>>> uniques
Categorical(['a', 'a', 'c'], categories=['a', 'b', 'c'])
```

(continues on next page)

(continued from previous page)

```
['a', 'c']
Categories (3, object): ['a', 'b', 'c']
```

Notice that 'b' is in `uniques.categories`, despite not being present in `cat.values`.

For all other pandas objects, an Index of the appropriate type is returned.

```
>>> cat = pd.Series(['a', 'a', 'c'])
>>> codes, uniques = pd.factorize(cat)
>>> codes
array([0, 0, 1])
>>> uniques
Index(['a', 'c'], dtype='object')
```

If NaN is in the values, and we want to include NaN in the uniques of the values, it can be achieved by setting `na_sentinel=None`.

```
>>> values = np.array([1, 2, 1, np.nan])
>>> codes, uniques = pd.factorize(values) # default: na_sentinel=-1
>>> codes
array([ 0,  1,  0, -1])
>>> uniques
array([1., 2.])
```

```
>>> codes, uniques = pd.factorize(values, na_sentinel=None)
>>> codes
array([0, 1, 0, 2])
>>> uniques
array([ 1.,  2., nan])
```

pandas.unique

`pandas.unique(values)`

Return unique values based on a hash table.

Uniques are returned in order of appearance. This does NOT sort.

Significantly faster than numpy.unique for long enough sequences. Includes NA values.

Parameters

`values` [1d array-like]

Returns

`numpy.ndarray or ExtensionArray` The return can be:

- Index : when the input is an Index
- Categorical : when the input is a Categorical dtype
- ndarray : when the input is a Series/ndarray

Return numpy.ndarray or ExtensionArray.

See also:

`Index.unique` Return unique values from an Index.

`Series.unique` Return unique values of Series object.

Examples

```
>>> pd.unique(pd.Series([2, 1, 3]))
array([2, 1, 3])
```

```
>>> pd.unique(pd.Series([2] + [1] * 5))
array([2, 1])
```

```
>>> pd.unique(pd.Series([pd.Timestamp("20160101"), pd.Timestamp("20160101")]))
array(['2016-01-01T00:00:00.000000000'], dtype='datetime64[ns]')
```

```
>>> pd.unique(
...     pd.Series(
...         [
...             pd.Timestamp("20160101", tz="US/Eastern"),
...             pd.Timestamp("20160101", tz="US/Eastern"),
...         ]
...     )
... )
<DatetimeArray>
['2016-01-01 00:00:00-05:00']
Length: 1, dtype: datetime64[ns, US/Eastern]
```

```
>>> pd.unique(
...     pd.Index(
...         [
...             pd.Timestamp("20160101", tz="US/Eastern"),
...             pd.Timestamp("20160101", tz="US/Eastern"),
...         ]
...     )
... )
DatetimeIndex(['2016-01-01 00:00:00-05:00'],
               dtype='datetime64[ns, US/Eastern]',
               freq=None)
```

```
>>> pd.unique(list("baabc"))
array(['b', 'a', 'c'], dtype=object)
```

An unordered Categorical will return categories in the order of appearance.

```
>>> pd.unique(pd.Series(pd.Categorical(list("baabc"))))
['b', 'a', 'c']
Categories (3, object): ['a', 'b', 'c']
```

```
>>> pd.unique(pd.Series(pd.Categorical(list("baabc"), categories=list("abc"))))
['b', 'a', 'c']
Categories (3, object): ['a', 'b', 'c']
```

An ordered Categorical preserves the category ordering.

```
>>> pd.unique(  
...     pd.Series(  
...         pd.Categorical(list("baabc"), categories=list("abc"), ordered=True)  
...     )  
... )  
['b', 'a', 'c']  
Categories (3, object): ['a' < 'b' < 'c']
```

An array of tuples

```
>>> pd.unique([(“a”, “b”), (“b”, “a”), (“a”, “c”), (“b”, “a”)])  
array([(‘a’, ‘b’), (‘b’, ‘a’), (‘a’, ‘c’)], dtype=object)
```

pandas.wide_to_long

`pandas.wide_to_long(df, stubnames, i, j, sep=”, suffix=’\d+’)`

Unpivot a DataFrame from wide to long format.

Less flexible but more user-friendly than melt.

With stubnames [‘A’, ‘B’], this function expects to find one or more group of columns with format A-suffix1, A-suffix2,..., B-suffix1, B-suffix2,... You specify what you want to call this suffix in the resulting long format with *j* (for example *j*=‘year’)

Each row of these wide variables are assumed to be uniquely identified by *i* (can be a single column name or a list of column names)

All remaining variables in the data frame are left intact.

Parameters

df [DataFrame] The wide-format DataFrame.

stubnames [str or list-like] The stub name(s). The wide format variables are assumed to start with the stub names.

i [str or list-like] Column(s) to use as id variable(s).

j [str] The name of the sub-observation variable. What you wish to name your suffix in the long format.

sep [str, default “”] A character indicating the separation of the variable names in the wide format, to be stripped from the names in the long format. For example, if your column names are A-suffix1, A-suffix2, you can strip the hyphen by specifying *sep*=‘-’.

suffix [str, default ‘\d+’] A regular expression capturing the wanted suffixes. ‘\d+’ captures numeric suffixes. Suffixes with no numbers could be specified with the negated character class ‘D+’. You can also further disambiguate suffixes, for example, if your wide variables are of the form A-one, B-two,..., and you have an unrelated column A-rating, you can ignore the last one by specifying *suffix*=‘(?!one|two)’. When all suffixes are numeric, they are cast to int64/float64.

Returns

DataFrame A DataFrame that contains each stub name as a variable, with new index (i, j).

See also:

melt Unpivot a DataFrame from wide to long format, optionally leaving identifiers set.

pivot Create a spreadsheet-style pivot table as a DataFrame.

DataFrame.pivot Pivot without aggregation that can handle non-numeric data.

DataFrame.pivot_table Generalization of pivot that can handle duplicate values for one index/column pair.

DataFrame.unstack Pivot based on the index values instead of a column.

Notes

All extra variables are left untouched. This simply uses `pandas.melt` under the hood, but is hard-coded to “do the right thing” in a typical case.

Examples

```
>>> np.random.seed(123)
>>> df = pd.DataFrame({ "A1970" : {0 : "a", 1 : "b", 2 : "c"}, ...
...                               "A1980" : {0 : "d", 1 : "e", 2 : "f"}, ...
...                               "B1970" : {0 : 2.5, 1 : 1.2, 2 : .7}, ...
...                               "B1980" : {0 : 3.2, 1 : 1.3, 2 : .1}, ...
...                               "X"      : dict(zip(range(3), np.random.randn(3))) ...
... })
>>> df["id"] = df.index
>>> df
   A1970  A1980  B1970  B1980          X  id
0      a      d    2.5    3.2 -1.085631  0
1      b      e    1.2    1.3  0.997345  1
2      c      f    0.7    0.1  0.282978  2
>>> pd.wide_to_long(df, ["A", "B"], i="id", j="year")
...
      X  A     B
id year
0  1970 -1.085631  a  2.5
1  1970  0.997345  b  1.2
2  1970  0.282978  c  0.7
0  1980 -1.085631  d  3.2
1  1980  0.997345  e  1.3
2  1980  0.282978  f  0.1
```

With multiple id columns

```
>>> df = pd.DataFrame({
...     'famid': [1, 1, 1, 2, 2, 2, 3, 3, 3],
...     'birth': [1, 2, 3, 1, 2, 3, 1, 2, 3],
...     'ht1': [2.8, 2.9, 2.2, 2, 1.8, 1.9, 2.2, 2.3, 2.1],
...     'ht2': [3.4, 3.8, 2.9, 3.2, 2.8, 2.4, 3.3, 3.4, 2.9]
... })
>>> df
   famid  birth  ht1  ht2
0       1      1  2.8  3.4
1       1      2  2.9  3.8
2       1      3  2.2  2.9
3       2      1  2.0  3.2
```

(continues on next page)

(continued from previous page)

```

4      2      2  1.8  2.8
5      2      3  1.9  2.4
6      3      1  2.2  3.3
7      3      2  2.3  3.4
8      3      3  2.1  2.9
>>> l = pd.wide_to_long(df, stubnames='ht', i=['famid', 'birth'], j='age')
>>> l
...
          ht
famid birth age
1      1    1  2.8
        2  3.4
        2    1  2.9
        2  3.8
        3    1  2.2
        2  2.9
2      1    1  2.0
        2  3.2
        2    1  1.8
        2  2.8
        3    1  1.9
        2  2.4
3      1    1  2.2
        2  3.3
        2    1  2.3
        2  3.4
        3    1  2.1
        2  2.9

```

Going from long back to wide just takes some creative use of *unstack*

```

>>> w = l.unstack()
>>> w.columns = w.columns.map('{0[0]}{0[1]}'.format)
>>> w.reset_index()
   famid  birth  ht1  ht2
0      1      1  2.8  3.4
1      1      2  2.9  3.8
2      1      3  2.2  2.9
3      2      1  2.0  3.2
4      2      2  1.8  2.8
5      2      3  1.9  2.4
6      3      1  2.2  3.3
7      3      2  2.3  3.4
8      3      3  2.1  2.9

```

Less wieldy column names are also handled

```

>>> np.random.seed(0)
>>> df = pd.DataFrame({'A(weekly)-2010': np.random.rand(3),
...                      'A(weekly)-2011': np.random.rand(3),
...                      'B(weekly)-2010': np.random.rand(3),
...                      'B(weekly)-2011': np.random.rand(3),
...                      })

```

(continues on next page)

(continued from previous page)

```

...
'X' : np.random.randint(3, size=3)})  

>>> df['id'] = df.index  

>>> df
   A(weekly)-2010  A(weekly)-2011  B(weekly)-2010  B(weekly)-2011  X  id
0      0.548814      0.544883      0.437587      0.383442  0   0
1      0.715189      0.423655      0.891773      0.791725  1   1
2      0.602763      0.645894      0.963663      0.528895  1   2

```

```

>>> pd.wide_to_long(df, ['A(weekly)', 'B(weekly)'], i='id',
...                   j='year', sep='-')
...
   X  A(weekly)  B(weekly)
id year
0  2010  0    0.548814  0.437587
1  2010  1    0.715189  0.891773
2  2010  1    0.602763  0.963663
0  2011  0    0.544883  0.383442
1  2011  1    0.423655  0.791725
2  2011  1    0.645894  0.528895

```

If we have many columns, we could also use a regex to find our stubnames and pass that list on to wide_to_long

```

>>> stubnames = sorted(  

...     set([match[0] for match in df.columns.str.findall(  

...         r'[A-B]\(.*\)').values if match != []]))  

... )  

>>> list(stubnames)  

['A(weekly)', 'B(weekly)']

```

All of the above examples have integers as suffixes. It is possible to have non-integers as suffixes.

```

>>> df = pd.DataFrame({  

...     'famid': [1, 1, 1, 2, 2, 2, 3, 3, 3],  

...     'birth': [1, 2, 3, 1, 2, 3, 1, 2, 3],  

...     'ht_one': [2.8, 2.9, 2.2, 2, 1.8, 1.9, 2.2, 2.3, 2.1],  

...     'ht_two': [3.4, 3.8, 2.9, 3.2, 2.8, 2.4, 3.3, 3.4, 2.9]  

... })  

>>> df
   famid  birth  ht_one  ht_two  

0       1      1    2.8    3.4  

1       1      2    2.9    3.8  

2       1      3    2.2    2.9  

3       2      1    2.0    3.2  

4       2      2    1.8    2.8  

5       2      3    1.9    2.4  

6       3      1    2.2    3.3  

7       3      2    2.3    3.4  

8       3      3    2.1    2.9

```

```

>>> l = pd.wide_to_long(df, stubnames='ht', i=['famid', 'birth'], j='age',  

...                      sep='_', suffix=r'\w+')
>>> l

```

(continues on next page)

(continued from previous page)

```

...

3.2.2 Top-level missing data

<code>isna(obj)</code>	Detect missing values for an array-like object.
<code>isnull(obj)</code>	Detect missing values for an array-like object.
<code>notna(obj)</code>	Detect non-missing values for an array-like object.
<code>notnull(obj)</code>	Detect non-missing values for an array-like object.

pandas.isna

`pandas.isna(obj)`

Detect missing values for an array-like object.

This function takes a scalar or array-like object and indicates whether values are missing (NaN in numeric arrays, None or NaN in object arrays, NaT in datetimelike).

Parameters

obj [scalar or array-like] Object to check for null or missing values.

Returns

bool or array-like of bool For scalar input, returns a scalar boolean. For array input, returns an array of boolean indicating whether each corresponding element is missing.

See also:

`notna` Boolean inverse of pandas.isna.

`Series.isna` Detect missing values in a Series.

`DataFrame.isna` Detect missing values in a DataFrame.

`Index.isna` Detect missing values in an Index.

Examples

Scalar arguments (including strings) result in a scalar boolean.

```
>>> pd.isna('dog')
False
```

```
>>> pd.isna(pd.NA)
True
```

```
>>> pd.isna(np.nan)
True
```

ndarrays result in an ndarray of booleans.

```
>>> array = np.array([[1, np.nan, 3], [4, 5, np.nan]])
>>> array
array([[ 1., nan,  3.],
       [ 4.,  5., nan]])
>>> pd.isna(array)
array([[False,  True, False],
       [False, False,  True]])
```

For indexes, an ndarray of booleans is returned.

```
>>> index = pd.DatetimeIndex(["2017-07-05", "2017-07-06", None,
...                             "2017-07-08"])
>>> index
DatetimeIndex(['2017-07-05', '2017-07-06', 'NaT', '2017-07-08'],
               dtype='datetime64[ns]', freq=None)
>>> pd.isna(index)
array([False, False,  True, False])
```

For Series and DataFrame, the same type is returned, containing booleans.

```
>>> df = pd.DataFrame([['ant', 'bee', 'cat'], ['dog', None, 'fly']])
>>> df
   0      1      2
0  ant    bee   cat
1  dog    None   fly
>>> pd.isna(df)
   0      1      2
0  False  False  False
1  False   True  False
```

```
>>> pd.isna(df[1])
0  False
1   True
Name: 1, dtype: bool
```

pandas.isnull

`pandas.isnull(obj)`

Detect missing values for an array-like object.

This function takes a scalar or array-like object and indicates whether values are missing (NaN in numeric arrays, None or NaN in object arrays, NaT in datetimelike).

Parameters

`obj` [scalar or array-like] Object to check for null or missing values.

Returns

bool or array-like of bool For scalar input, returns a scalar boolean. For array input, returns an array of boolean indicating whether each corresponding element is missing.

See also:

`notna` Boolean inverse of pandas.isna.

`Series.isna` Detect missing values in a Series.

`DataFrame.isna` Detect missing values in a DataFrame.

`Index.isna` Detect missing values in an Index.

Examples

Scalar arguments (including strings) result in a scalar boolean.

```
>>> pd.isna('dog')
False
```

```
>>> pd.isna(pd.NA)
True
```

```
>>> pd.isna(np.nan)
True
```

ndarrays result in an ndarray of booleans.

```
>>> array = np.array([[1, np.nan, 3], [4, 5, np.nan]])
>>> array
array([[ 1., nan,  3.],
       [ 4.,  5., nan]])
>>> pd.isna(array)
array([[False,  True, False],
       [False, False,  True]])
```

For indexes, an ndarray of booleans is returned.

```
>>> index = pd.DatetimeIndex(['2017-07-05', '2017-07-06', None,
...                            '2017-07-08'])
>>> index
DatetimeIndex(['2017-07-05', '2017-07-06', 'NaT', '2017-07-08'],
               dtype='datetime64[ns]', freq=None)
```

(continues on next page)

(continued from previous page)

```
>>> pd.isna(index)
array([False, False, True, False])
```

For Series and DataFrame, the same type is returned, containing booleans.

```
>>> df = pd.DataFrame([['ant', 'bee', 'cat'], ['dog', None, 'fly']])
>>> df
   0    1    2
0 ant  bee  cat
1 dog  None  fly
>>> pd.isna(df)
   0    1    2
0 False False False
1 False  True  False
```

```
>>> pd.isna(df[1])
0    False
1     True
Name: 1, dtype: bool
```

pandas.notna

`pandas.notna(obj)`

Detect non-missing values for an array-like object.

This function takes a scalar or array-like object and indicates whether values are valid (not missing, which is `NaN` in numeric arrays, `None` or `NaN` in object arrays, `NaT` in datetimelike).

Parameters

`obj` [array-like or object value] Object to check for *not* null or *non*-missing values.

Returns

bool or array-like of bool For scalar input, returns a scalar boolean. For array input, returns an array of boolean indicating whether each corresponding element is valid.

See also:

[`isna`](#) Boolean inverse of `pandas.notna`.

[`Series.notna`](#) Detect valid values in a Series.

[`DataFrame.notna`](#) Detect valid values in a DataFrame.

[`Index.notna`](#) Detect valid values in an Index.

Examples

Scalar arguments (including strings) result in a scalar boolean.

```
>>> pd.notna('dog')
True
```

```
>>> pd.notna(pd.NA)
False
```

```
>>> pd.notna(np.nan)
False
```

ndarrays result in an ndarray of booleans.

```
>>> array = np.array([[1, np.nan, 3], [4, 5, np.nan]])
>>> array
array([[ 1., nan,  3.],
       [ 4.,  5., nan]])
>>> pd.notna(array)
array([[ True, False,  True],
       [ True,  True, False]])
```

For indexes, an ndarray of booleans is returned.

```
>>> index = pd.DatetimeIndex(["2017-07-05", "2017-07-06", None,
...                            "2017-07-08"])
>>> index
DatetimeIndex(['2017-07-05', '2017-07-06', 'NaT', '2017-07-08'],
               dtype='datetime64[ns]', freq=None)
>>> pd.notna(index)
array([ True,  True, False,  True])
```

For Series and DataFrame, the same type is returned, containing booleans.

```
>>> df = pd.DataFrame([['ant', 'bee', 'cat'], ['dog', None, 'fly']])
>>> df
   0      1      2
0 ant    bee   cat
1 dog    None   fly
>>> pd.notna(df)
   0      1      2
0  True   True   True
1  True  False   True
```

```
>>> pd.notna(df[1])
0      True
1     False
Name: 1, dtype: bool
```

pandas.notnull

`pandas.notnull(obj)`

Detect non-missing values for an array-like object.

This function takes a scalar or array-like object and indicates whether values are valid (not missing, which is `NaN` in numeric arrays, `None` or `NaN` in object arrays, `NaT` in datetimelike).

Parameters

`obj` [array-like or object value] Object to check for *not null* or *non-missing* values.

Returns

bool or array-like of bool For scalar input, returns a scalar boolean. For array input, returns an array of boolean indicating whether each corresponding element is valid.

See also:

`isna` Boolean inverse of `pandas.notna`.

`Series.notna` Detect valid values in a Series.

`DataFrame.notna` Detect valid values in a DataFrame.

`Index.notna` Detect valid values in an Index.

Examples

Scalar arguments (including strings) result in a scalar boolean.

```
>>> pd.notna('dog')
True
```

```
>>> pd.notna(pd.NA)
False
```

```
>>> pd.notna(np.nan)
False
```

ndarrays result in an ndarray of booleans.

```
>>> array = np.array([[1, np.nan, 3], [4, 5, np.nan]])
>>> array
array([[ 1., nan,  3.],
       [ 4.,  5., nan]])
>>> pd.notna(array)
array([[ True, False,  True],
       [ True,  True, False]])
```

For indexes, an ndarray of booleans is returned.

```
>>> index = pd.DatetimeIndex(['2017-07-05', '2017-07-06', None,
...                            '2017-07-08'])
>>> index
DatetimeIndex(['2017-07-05', '2017-07-06', 'NaT', '2017-07-08'],
               dtype='datetime64[ns]', freq=None)
```

(continues on next page)

(continued from previous page)

```
>>> pd.notna(index)
array([ True,  True, False,  True])
```

For Series and DataFrame, the same type is returned, containing booleans.

```
>>> df = pd.DataFrame([['ant', 'bee', 'cat'], ['dog', None, 'fly']])
>>> df
   0    1    2
0 ant  bee  cat
1 dog  None  fly
>>> pd.notna(df)
   0    1    2
0  True  True  True
1  True False  True
```

```
>>> pd.notna(df[1])
0    True
1   False
Name: 1, dtype: bool
```

3.2.3 Top-level dealing with numeric data

`to_numeric(arg[, errors, downcast])`

Convert argument to a numeric type.

pandas.to_numeric

`pandas.to_numeric(arg, errors='raise', downcast=None)`

Convert argument to a numeric type.

The default return dtype is `float64` or `int64` depending on the data supplied. Use the `downcast` parameter to obtain other dtypes.

Please note that precision loss may occur if really large numbers are passed in. Due to the internal limitations of `ndarray`, if numbers smaller than `-9223372036854775808` (`np.iinfo(np.int64).min`) or larger than `18446744073709551615` (`np.iinfo(np.uint64).max`) are passed in, it is very likely they will be converted to float so that they can be stored in an `ndarray`. These warnings apply similarly to `Series` since it internally leverages `ndarray`.

Parameters

arg [scalar, list, tuple, 1-d array, or Series] Argument to be converted.

errors [{‘ignore’, ‘raise’, ‘coerce’}, default ‘raise’]

- If ‘raise’, then invalid parsing will raise an exception.
- If ‘coerce’, then invalid parsing will be set as NaN.
- If ‘ignore’, then invalid parsing will return the input.

downcast [str, default None] Can be ‘integer’, ‘signed’, ‘unsigned’, or ‘float’. If not None, and if the data has been successfully cast to a numerical dtype (or if the data was numeric to begin with), downcast that resulting data to the smallest numerical dtype possible according to the following rules:

- ‘integer’ or ‘signed’: smallest signed int dtype (min.: np.int8)
- ‘unsigned’: smallest unsigned int dtype (min.: np.uint8)
- ‘float’: smallest float dtype (min.: np.float32)

As this behaviour is separate from the core conversion to numeric values, any errors raised during the downcasting will be surfaced regardless of the value of the ‘errors’ input.

In addition, downcasting will only occur if the size of the resulting data’s dtype is strictly larger than the dtype it is to be cast to, so if none of the dtypes checked satisfy that specification, no downcasting will be performed on the data.

Returns

ret Numeric if parsing succeeded. Return type depends on input. Series if Series, otherwise ndarray.

See also:

[DataFrame.astype](#) Cast argument to a specified dtype.

[to_datetime](#) Convert argument to datetime.

[to_timedelta](#) Convert argument to timedelta.

[numpy.ndarray.astype](#) Cast a numpy array to a specified type.

[DataFrame.convert_dtypes](#) Convert dtypes.

Examples

Take separate series and convert to numeric, coercing when told to

```
>>> s = pd.Series(['1.0', '2', '-3'])
>>> pd.to_numeric(s)
0    1.0
1    2.0
2   -3.0
dtype: float64
>>> pd.to_numeric(s, downcast='float')
0    1.0
1    2.0
2   -3.0
dtype: float32
>>> pd.to_numeric(s, downcast='signed')
0    1
1    2
2   -3
dtype: int8
>>> s = pd.Series(['apple', '1.0', '2', '-3'])
>>> pd.to_numeric(s, errors='ignore')
0    apple
1    1.0
2     2
3    -3
dtype: object
>>> pd.to_numeric(s, errors='coerce')
```

(continues on next page)

(continued from previous page)

```
0    NaN
1    1.0
2    2.0
3   -3.0
dtype: float64
```

Downcasting of nullable integer and floating dtypes is supported:

```
>>> s = pd.Series([1, 2, 3], dtype="Int64")
>>> pd.to_numeric(s, downcast="integer")
0    1
1    2
2    3
dtype: Int8
>>> s = pd.Series([1.0, 2.1, 3.0], dtype="Float64")
>>> pd.to_numeric(s, downcast="float")
0    1.0
1    2.1
2    3.0
dtype: Float32
```

3.2.4 Top-level dealing with datetimelike data

<code>to_datetime(arg[, errors, dayfirst, ...])</code>	Convert argument to datetime.
<code>to_timedelta(arg[, unit, errors])</code>	Convert argument to timedelta.
<code>date_range([start, end, periods, freq, tz, ...])</code>	Return a fixed frequency DatetimeIndex.
<code>bdate_range([start, end, periods, freq, tz, ...])</code>	Return a fixed frequency DatetimeIndex, with business day as the default frequency.
<code>period_range([start, end, periods, freq, name])</code>	Return a fixed frequency PeriodIndex.
<code>timedelta_range([start, end, periods, freq, ...])</code>	Return a fixed frequency TimedeltaIndex, with day as the default frequency.
<code>infer_freq(index[, warn])</code>	Infer the most likely frequency given the input index.

pandas.to_datetime

```
pandas.to_datetime(arg, errors='raise', dayfirst=False, yearfirst=False, utc=None, format=None, exact=True,
                   unit=None, infer_datetime_format=False, origin='unix', cache=True)
```

Convert argument to datetime.

This function converts a scalar, array-like, `Series` or `DataFrame`/dict-like to a pandas datetime object.

Parameters

arg [int, float, str, datetime, list, tuple, 1-d array, Series, DataFrame/dict-like] The object to convert to a datetime. If a `DataFrame` is provided, the method expects minimally the following columns: "year", "month", "day".

errors [{‘ignore’, ‘raise’, ‘coerce’}], default ‘raise’]

- If ‘raise’, then invalid parsing will raise an exception.
- If ‘coerce’, then invalid parsing will be set as NaT.

- If 'ignore', then invalid parsing will return the input.

dayfirst [bool, default False] Specify a date parse order if *arg* is str or is list-like. If True, parses dates with the day first, e.g. "10/11/12" is parsed as 2012-11-10.

Warning: `dayfirst=True` is not strict, but will prefer to parse with day first. If a delimited date string cannot be parsed in accordance with the given `dayfirst` option, e.g. `to_datetime(['31-12-2021'])`, then a warning will be shown.

yearfirst [bool, default False] Specify a date parse order if *arg* is str or is list-like.

- If True parses dates with the year first, e.g. "10/11/12" is parsed as 2010-11-12.
- If both `dayfirst` and `yearfirst` are True, `yearfirst` is preceded (same as `dateutil`).

Warning: `yearfirst=True` is not strict, but will prefer to parse with year first.

utc [bool, default None] Control timezone-related parsing, localization and conversion.

- If True, the function *always* returns a timezone-aware UTC-localized `Timestamp`, `Series` or `DatetimeIndex`. To do this, timezone-naive inputs are *localized* as UTC, while timezone-aware inputs are *converted* to UTC.
- If False (default), inputs will not be coerced to UTC. Timezone-naive inputs will remain naive, while timezone-aware ones will keep their time offsets. Limitations exist for mixed offsets (typically, daylight savings), see `Examples` section for details.

See also: pandas general documentation about [timezone conversion and localization](#).

format [str, default None] The strftime to parse time, e.g. "%d/%m/%Y". Note that "%f" will parse all the way up to nanoseconds. See [strftime documentation](#) for more information on choices.

exact [bool, default True] Control how *format* is used:

- If True, require an exact *format* match.
- If False, allow the *format* to match anywhere in the target string.

unit [str, default 'ns'] The unit of the arg (D,s,ms,us,ns) denote the unit, which is an integer or float number. This will be based off the origin. Example, with `unit='ms'` and `origin='unix'` (the default), this would calculate the number of milliseconds to the unix epoch start.

infer_datetime_format [bool, default False] If True and no *format* is given, attempt to infer the format of the datetime strings based on the first non-NaN element, and if it can be inferred, switch to a faster method of parsing them. In some cases this can increase the parsing speed by ~5-10x.

origin [scalar, default 'unix'] Define the reference date. The numeric values would be parsed as number of units (defined by *unit*) since this reference date.

- If 'unix' (or POSIX) time; origin is set to 1970-01-01.
- If 'julian', unit must be 'D', and origin is set to beginning of Julian Calendar. Julian day number 0 is assigned to the day starting at noon on January 1, 4713 BC.
- If Timestamp convertible, origin is set to Timestamp identified by origin.

cache [bool, default True] If True, use a cache of unique, converted dates to apply the date-time conversion. May produce significant speed-up when parsing duplicate date strings, especially ones with timezone offsets. The cache is only used when there are at least 50 values. The presence of out-of-bounds values will render the cache unusable and may slow down parsing.

Changed in version 0.25.0: changed default value from False to True.

Returns

datetime If parsing succeeded. Return type depends on input (types in parenthesis correspond to fallback in case of unsuccessful timezone or out-of-range timestamp parsing):

- scalar: `Timestamp` (or `datetime.datetime`)
- array-like: `DatetimeIndex` (or `Series` with `object` dtype containing `datetime.datetime`)
- Series: `Series` of `datetime64` dtype (or `Series` of `object` dtype containing `datetime.datetime`)
- DataFrame: `Series` of `datetime64` dtype (or `Series` of `object` dtype containing `datetime.datetime`)

Raises

ParserError When parsing a date from string fails.

ValueError When another datetime conversion error happens. For example when one of ‘year’, ‘month’, ‘day’ columns is missing in a `DataFrame`, or when a Timezone-aware `datetime.datetime` is found in an array-like of mixed time offsets, and `utc=False`.

See also:

`DataFrame.astype` Cast argument to a specified dtype.

`to_timedelta` Convert argument to timedelta.

`convert_dtypes` Convert dtypes.

Notes

Many input types are supported, and lead to different output types:

- **scalars** can be int, float, str, datetime object (from stdlib `datetime` module or `numpy`). They are converted to `Timestamp` when possible, otherwise they are converted to `datetime.datetime`. None/NaN/null scalars are converted to NaT.
- **array-like** can contain int, float, str, datetime objects. They are converted to `DatetimeIndex` when possible, otherwise they are converted to `Index` with `object` dtype, containing `datetime.datetime`. None/NaN/null entries are converted to NaT in both cases.
- **Series** are converted to `Series` with `datetime64` dtype when possible, otherwise they are converted to `Series` with `object` dtype, containing `datetime.datetime`. None/NaN/null entries are converted to NaT in both cases.
- **DataFrame/dict-like** are converted to `Series` with `datetime64` dtype. For each row a datetime is created from assembling the various dataframe columns. Column keys can be common abbreviations like ['year', 'month', 'day', 'minute', 'second', 'ms', 'us', 'ns']) or plurals of the same.

The following causes are responsible for `datetime.datetime` objects being returned (possibly inside an `Index` or a `Series` with `object` dtype) instead of a proper pandas designated type (`Timestamp`, `DatetimeIndex` or `Series` with `datetime64` dtype):

- when any input element is before `Timestamp.min` or after `Timestamp.max`, see `timestamp` limitations.
- when `utc=False` (default) and the input is an array-like or `Series` containing mixed naive/aware datetime, or aware with mixed time offsets. Note that this happens in the (quite frequent) situation when the timezone has a daylight savings policy. In that case you may wish to use `utc=True`.

Examples

Handling various input formats

Assembling a datetime from multiple columns of a `DataFrame`. The keys can be common abbreviations like ['year', 'month', 'day', 'minute', 'second', 'ms', 'us', 'ns']) or plurals of the same

```
>>> df = pd.DataFrame({'year': [2015, 2016],
...                     'month': [2, 3],
...                     'day': [4, 5]})
>>> pd.to_datetime(df)
0    2015-02-04
1    2016-03-05
dtype: datetime64[ns]
```

Passing `infer_datetime_format=True` can often-times speedup a parsing if its not an ISO8601 format exactly, but in a regular format.

```
>>> s = pd.Series(['3/11/2000', '3/12/2000', '3/13/2000'] * 1000)
>>> s.head()
0    3/11/2000
1    3/12/2000
2    3/13/2000
3    3/11/2000
4    3/12/2000
dtype: object
```

```
>>> %timeit pd.to_datetime(s, infer_datetime_format=True)
100 loops, best of 3: 10.4 ms per loop
```

```
>>> %timeit pd.to_datetime(s, infer_datetime_format=False)
1 loop, best of 3: 471 ms per loop
```

Using a unix epoch time

```
>>> pd.to_datetime(1490195805, unit='s')
Timestamp('2017-03-22 15:16:45')
>>> pd.to_datetime(1490195805433502912, unit='ns')
Timestamp('2017-03-22 15:16:45.433502912')
```

Warning: For float arg, precision rounding might happen. To prevent unexpected behavior use a fixed-width exact type.

Using a non-unix epoch origin

```
>>> pd.to_datetime([1, 2, 3], unit='D',
...                 origin=pd.Timestamp('1960-01-01'))
DatetimeIndex(['1960-01-02', '1960-01-03', '1960-01-04'],
              dtype='datetime64[ns]', freq=None)
```

Non-convertible date/times

If a date does not meet the `timestamp` limitations, passing `errors='ignore'` will return the original input instead of raising any exception.

Passing `errors='coerce'` will force an out-of-bounds date to NaT, in addition to forcing non-dates (or non-parseable dates) to NaT.

```
>>> pd.to_datetime('13000101', format='%Y%m%d', errors='ignore')
datetime.datetime(1300, 1, 1, 0, 0)
>>> pd.to_datetime('13000101', format='%Y%m%d', errors='coerce')
NaT
```

Timezones and time offsets

The default behaviour (`utc=False`) is as follows:

- Timezone-naive inputs are converted to timezone-naive `DatetimeIndex`:

```
>>> pd.to_datetime(['2018-10-26 12:00', '2018-10-26 13:00:15'])
DatetimeIndex(['2018-10-26 12:00:00', '2018-10-26 13:00:15'],
              dtype='datetime64[ns]', freq=None)
```

- Timezone-aware inputs with *constant time offset* are converted to timezone-aware `DatetimeIndex`:

```
>>> pd.to_datetime(['2018-10-26 12:00 -0500', '2018-10-26 13:00 -0500'])
DatetimeIndex(['2018-10-26 12:00:00-05:00', '2018-10-26 13:00:00-05:00'],
              dtype='datetime64[ns, pytz.FixedOffset(-300)]', freq=None)
```

- However, timezone-aware inputs with *mixed time offsets* (for example issued from a timezone with daylight savings, such as Europe/Paris) are **not successfully converted** to a `DatetimeIndex`. Instead a simple `Index` containing `datetime.datetime` objects is returned:

```
>>> pd.to_datetime(['2020-10-25 02:00 +0200', '2020-10-25 04:00 +0100'])
Index([2020-10-25 02:00:00+02:00, 2020-10-25 04:00:00+01:00],
      dtype='object')
```

- A mix of timezone-aware and timezone-naive inputs is converted to a timezone-aware `DatetimeIndex` if the offsets of the timezone-aware are constant:

```
>>> from datetime import datetime
>>> pd.to_datetime(["2020-01-01 01:00 -01:00", datetime(2020, 1, 1, 3, 0)])
DatetimeIndex(['2020-01-01 01:00:00-01:00', '2020-01-01 02:00:00-01:00'],
              dtype='datetime64[ns, pytz.FixedOffset(-60)]', freq=None)
```

- Finally, mixing timezone-aware strings and `datetime.datetime` always raises an error, even if the elements all have the same time offset.

```
>>> from datetime import datetime, timezone, timedelta
>>> d = datetime(2020, 1, 1, 18, tzinfo=timezone(-timedelta(hours=1)))
>>> pd.to_datetime(['2020-01-01 17:00 -0100', d])
Traceback (most recent call last):
...
ValueError: Tz-aware datetime.datetime cannot be converted to datetime64
unless utc=True
```

Setting `utc=True` solves most of the above issues:

- Timezone-naive inputs are *localized* as UTC

```
>>> pd.to_datetime(['2018-10-26 12:00', '2018-10-26 13:00'], utc=True)
DatetimeIndex(['2018-10-26 12:00:00+00:00', '2018-10-26 13:00:00+00:00'],
              dtype='datetime64[ns, UTC]', freq=None)
```

- Timezone-aware inputs are *converted* to UTC (the output represents the exact same datetime, but viewed from the UTC time offset `+00:00`).

```
>>> pd.to_datetime(['2018-10-26 12:00 -0530', '2018-10-26 12:00 -0500'],
...                  utc=True)
DatetimeIndex(['2018-10-26 17:30:00+00:00', '2018-10-26 17:00:00+00:00'],
              dtype='datetime64[ns, UTC]', freq=None)
```

- Inputs can contain both naive and aware, string or datetime, the above rules still apply

```
>>> pd.to_datetime(['2018-10-26 12:00', '2018-10-26 12:00 -0530',
...                   ..., datetime(2020, 1, 1, 18),
...                   ..., datetime(2020, 1, 1, 18,
...                   ..., tzinfo=timezone(-timedelta(hours=1))),],
...                   ..., utc=True)
DatetimeIndex(['2018-10-26 12:00:00+00:00', '2018-10-26 17:30:00+00:00',
               '2020-01-01 18:00:00+00:00', '2020-01-01 19:00:00+00:00'],
              dtype='datetime64[ns, UTC]', freq=None)
```

pandas.to_timedelta

`pandas.to_timedelta(arg, unit=None, errors='raise')`

Convert argument to timedelta.

Timedeltas are absolute differences in times, expressed in difference units (e.g. days, hours, minutes, seconds). This method converts an argument from a recognized timedelta format / value into a Timedelta type.

Parameters

`arg` [str, timedelta, list-like or Series] The data to be converted to timedelta.

Deprecated since version 1.2: Strings with units ‘M’, ‘Y’ and ‘y’ do not represent unambiguous timedelta values and will be removed in a future version

unit [str, optional] Denotes the unit of the arg for numeric *arg*. Defaults to "ns".

Possible values:

- 'W'
- 'D' / 'days' / 'day'
- 'hours' / 'hour' / 'hr' / 'h'
- 'm' / 'minute' / 'min' / 'minutes' / 'T'
- 'S' / 'seconds' / 'sec' / 'second'
- 'ms' / 'milliseconds' / 'millisecond' / 'milli' / 'millis' / 'L'
- 'us' / 'microseconds' / 'microsecond' / 'micro' / 'micros' / 'U'
- 'ns' / 'nanoseconds' / 'nano' / 'nanos' / 'nanosecond' / 'N'

Changed in version 1.1.0: Must not be specified when *arg* context strings and `errors="raise"`.

errors [{‘ignore’, ‘raise’, ‘coerce’}, default ‘raise’]

- If ‘raise’, then invalid parsing will raise an exception.
- If ‘coerce’, then invalid parsing will be set as NaT.
- If ‘ignore’, then invalid parsing will return the input.

Returns

timedelta If parsing succeeded. Return type depends on input:

- list-like: TimedeltaIndex of timedelta64 dtype
- Series: Series of timedelta64 dtype
- scalar: Timedelta

See also:

[DataFrame.astype](#) Cast argument to a specified dtype.

[to_datetime](#) Convert argument to datetime.

[convert_dtypes](#) Convert dtypes.

Notes

If the precision is higher than nanoseconds, the precision of the duration is truncated to nanoseconds for string inputs.

Examples

Parsing a single string to a Timedelta:

```
>>> pd.to_timedelta('1 days 06:05:01.00003')
Timedelta('1 days 06:05:01.000030')
>>> pd.to_timedelta('15.5us')
Timedelta('0 days 00:00:00.000015500')
```

Parsing a list or array of strings:

```
>>> pd.to_timedelta(['1 days 06:05:01.00003', '15.5us', 'nan'])
TimedeltaIndex(['1 days 06:05:01.000030', '0 days 00:00:00.000015500', NaT],
               dtype='timedelta64[ns]', freq=None)
```

Converting numbers by specifying the *unit* keyword argument:

```
>>> pd.to_timedelta(np.arange(5), unit='s')
TimedeltaIndex(['0 days 00:00:00', '0 days 00:00:01', '0 days 00:00:02',
                '0 days 00:00:03', '0 days 00:00:04'],
                  dtype='timedelta64[ns]', freq=None)
>>> pd.to_timedelta(np.arange(5), unit='d')
TimedeltaIndex(['0 days', '1 days', '2 days', '3 days', '4 days'],
                  dtype='timedelta64[ns]', freq=None)
```

pandas.date_range

`pandas.date_range(start=None, end=None, periods=None, freq=None, tz=None, normalize=False, name=None, closed=NoDefault.no_default, inclusive=None, **kwargs)`

Return a fixed frequency DatetimeIndex.

Returns the range of equally spaced time points (where the difference between any two adjacent points is specified by the given frequency) such that they all satisfy $\text{start} \leq x \leq \text{end}$, where the first one and the last one are, resp., the first and last time points in that range that fall on the boundary of `freq` (if given as a frequency string) or that are valid for `freq` (if given as a `pandas.tseries.offsets.DateOffset`). (If exactly one of `start`, `end`, or `freq` is *not* specified, this missing parameter can be computed given `periods`, the number of timesteps in the range. See the note below.)

Parameters

- start** [str or datetime-like, optional] Left bound for generating dates.
- end** [str or datetime-like, optional] Right bound for generating dates.
- periods** [int, optional] Number of periods to generate.
- freq** [str or DateOffset, default ‘D’] Frequency strings can have multiples, e.g. ‘5H’. See [here](#) for a list of frequency aliases.
- tz** [str or tzinfo, optional] Time zone name for returning localized DatetimeIndex, for example ‘Asia/Hong_Kong’. By default, the resulting DatetimeIndex is timezone-naive.
- normalize** [bool, default False] Normalize start/end dates to midnight before generating date range.
- name** [str, default None] Name of the resulting DatetimeIndex.

closed [{None, ‘left’, ‘right’}, optional] Make the interval closed with respect to the given frequency to the ‘left’, ‘right’, or both sides (None, the default).

Deprecated since version 1.4.0: Argument *closed* has been deprecated to standardize boundary inputs. Use *inclusive* instead, to set each bound as closed or open.

inclusive [{“both”, “neither”, “left”, “right”}, default “both”] Include boundaries; Whether to set each bound as closed or open.

New in version 1.4.0.

****kwargs** For compatibility. Has no effect on the result.

Returns

rng [DatetimeIndex]

See also:

DatetimeIndex An immutable container for datetimes.

timedelta_range Return a fixed frequency TimedeltaIndex.

period_range Return a fixed frequency PeriodIndex.

interval_range Return a fixed frequency IntervalIndex.

Notes

Of the four parameters `start`, `end`, `periods`, and `freq`, exactly three must be specified. If `freq` is omitted, the resulting DatetimeIndex will have `periods` linearly spaced elements between `start` and `end` (closed on both sides).

To learn more about the frequency strings, please see [this link](#).

Examples

Specifying the values

The next four examples generate the same `DatetimeIndex`, but vary the combination of `start`, `end` and `periods`.

Specify `start` and `end`, with the default daily frequency.

```
>>> pd.date_range(start='1/1/2018', end='1/08/2018')
DatetimeIndex(['2018-01-01', '2018-01-02', '2018-01-03', '2018-01-04',
               '2018-01-05', '2018-01-06', '2018-01-07', '2018-01-08'],
              dtype='datetime64[ns]', freq='D')
```

Specify `start` and `periods`, the number of periods (days).

```
>>> pd.date_range(start='1/1/2018', periods=8)
DatetimeIndex(['2018-01-01', '2018-01-02', '2018-01-03', '2018-01-04',
               '2018-01-05', '2018-01-06', '2018-01-07', '2018-01-08'],
              dtype='datetime64[ns]', freq='D')
```

Specify `end` and `periods`, the number of periods (days).

```
>>> pd.date_range(end='1/1/2018', periods=8)
DatetimeIndex(['2017-12-25', '2017-12-26', '2017-12-27', '2017-12-28',
               '2017-12-29', '2017-12-30', '2017-12-31', '2018-01-01'],
              dtype='datetime64[ns]', freq='D')
```

Specify *start*, *end*, and *periods*; the frequency is generated automatically (linearly spaced).

```
>>> pd.date_range(start='2018-04-24', end='2018-04-27', periods=3)
DatetimeIndex(['2018-04-24 00:00:00', '2018-04-25 12:00:00',
               '2018-04-27 00:00:00'],
              dtype='datetime64[ns]', freq=None)
```

Other Parameters

Changed the *freq* (frequency) to 'M' (month end frequency).

```
>>> pd.date_range(start='1/1/2018', periods=5, freq='M')
DatetimeIndex(['2018-01-31', '2018-02-28', '2018-03-31', '2018-04-30',
               '2018-05-31'],
              dtype='datetime64[ns]', freq='M')
```

Multiples are allowed

```
>>> pd.date_range(start='1/1/2018', periods=5, freq='3M')
DatetimeIndex(['2018-01-31', '2018-04-30', '2018-07-31', '2018-10-31',
               '2019-01-31'],
              dtype='datetime64[ns]', freq='3M')
```

freq can also be specified as an Offset object.

```
>>> pd.date_range(start='1/1/2018', periods=5, freq=pd.offsets.MonthEnd(3))
DatetimeIndex(['2018-01-31', '2018-04-30', '2018-07-31', '2018-10-31',
               '2019-01-31'],
              dtype='datetime64[ns]', freq='3M')
```

Specify *tz* to set the timezone.

```
>>> pd.date_range(start='1/1/2018', periods=5, tz='Asia/Tokyo')
DatetimeIndex(['2018-01-01 00:00:00+09:00', '2018-01-02 00:00:00+09:00',
               '2018-01-03 00:00:00+09:00', '2018-01-04 00:00:00+09:00',
               '2018-01-05 00:00:00+09:00'],
              dtype='datetime64[ns, Asia/Tokyo]', freq='D')
```

inclusive controls whether to include *start* and *end* that are on the boundary. The default, "both", includes boundary points on either end.

```
>>> pd.date_range(start='2017-01-01', end='2017-01-04', inclusive="both")
DatetimeIndex(['2017-01-01', '2017-01-02', '2017-01-03', '2017-01-04'],
              dtype='datetime64[ns]', freq='D')
```

Use *inclusive='left'* to exclude *end* if it falls on the boundary.

```
>>> pd.date_range(start='2017-01-01', end='2017-01-04', inclusive='left')
DatetimeIndex(['2017-01-01', '2017-01-02', '2017-01-03'],
              dtype='datetime64[ns]', freq='D')
```

Use `inclusive='right'` to exclude `start` if it falls on the boundary, and similarly `inclusive='neither'` will exclude both `start` and `end`.

```
>>> pd.date_range(start='2017-01-01', end='2017-01-04', inclusive='right')
DatetimeIndex(['2017-01-02', '2017-01-03', '2017-01-04'],
              dtype='datetime64[ns]', freq='D')
```

pandas.bdate_range

`pandas.bdate_range(start=None, end=None, periods=None, freq='B', tz=None, normalize=True, name=None, weekmask=None, holidays=None, closed=NoDefault.no_default, inclusive=None, **kwargs)`

Return a fixed frequency DatetimeIndex, with business day as the default frequency.

Parameters

`start` [str or datetime-like, default None] Left bound for generating dates.

`end` [str or datetime-like, default None] Right bound for generating dates.

`periods` [int, default None] Number of periods to generate.

`freq` [str or DateOffset, default ‘B’ (business daily)] Frequency strings can have multiples, e.g. ‘5H’.

`tz` [str or None] Time zone name for returning localized DatetimeIndex, for example Asia/Beijing.

`normalize` [bool, default False] Normalize start/end dates to midnight before generating date range.

`name` [str, default None] Name of the resulting DatetimeIndex.

`weekmask` [str or None, default None] Weekmask of valid business days, passed to `numpy.busdaycalendar`, only used when custom frequency strings are passed. The default value None is equivalent to ‘Mon Tue Wed Thu Fri’.

`holidays` [list-like or None, default None] Dates to exclude from the set of valid business days, passed to `numpy.busdaycalendar`, only used when custom frequency strings are passed.

`closed` [str, default None] Make the interval closed with respect to the given frequency to the ‘left’, ‘right’, or both sides (None).

Deprecated since version 1.4.0: Argument `closed` has been deprecated to standardize boundary inputs. Use `inclusive` instead, to set each bound as closed or open.

`inclusive` [{“both”, “neither”, “left”, “right”}, default “both”] Include boundaries; Whether to set each bound as closed or open.

New in version 1.4.0.

`**kwargs` For compatibility. Has no effect on the result.

Returns

`DatetimeIndex`

Notes

Of the four parameters: `start`, `end`, `periods`, and `freq`, exactly three must be specified. Specifying `freq` is a requirement for `bdate_range`. Use `date_range` if specifying `freq` is not desired.

To learn more about the frequency strings, please see [this link](#).

Examples

Note how the two weekend days are skipped in the result.

```
>>> pd.bdate_range(start='1/1/2018', end='1/08/2018')
DatetimeIndex(['2018-01-01', '2018-01-02', '2018-01-03', '2018-01-04',
               '2018-01-05', '2018-01-08'],
              dtype='datetime64[ns]', freq='B')
```

pandas.period_range

`pandas.period_range(start=None, end=None, periods=None, freq=None, name=None)`

Return a fixed frequency PeriodIndex.

The day (calendar) is the default frequency.

Parameters

`start` [str or period-like, default None] Left bound for generating periods.

`end` [str or period-like, default None] Right bound for generating periods.

`periods` [int, default None] Number of periods to generate.

`freq` [str or DateOffset, optional] Frequency alias. By default the freq is taken from `start` or `end` if those are Period objects. Otherwise, the default is "D" for daily frequency.

`name` [str, default None] Name of the resulting PeriodIndex.

Returns

`PeriodIndex`

Notes

Of the three parameters: `start`, `end`, and `periods`, exactly two must be specified.

To learn more about the frequency strings, please see [this link](#).

Examples

```
>>> pd.period_range(start='2017-01-01', end='2018-01-01', freq='M')
PeriodIndex(['2017-01', '2017-02', '2017-03', '2017-04', '2017-05', '2017-06',
             '2017-07', '2017-08', '2017-09', '2017-10', '2017-11', '2017-12',
             '2018-01'],
            dtype='period[M]')
```

If `start` or `end` are Period objects, they will be used as anchor endpoints for a PeriodIndex with frequency matching that of the period_range constructor.

```
>>> pd.period_range(start=pd.Period('2017Q1', freq='Q'),
...                   end=pd.Period('2017Q2', freq='Q'), freq='M')
PeriodIndex(['2017-03', '2017-04', '2017-05', '2017-06'],
            dtype='period[M]')
```

pandas.timedelta_range

`pandas.timedelta_range(start=None, end=None, periods=None, freq=None, name=None, closed=None)`
Return a fixed frequency TimedeltaIndex, with day as the default frequency.

Parameters

`start` [str or timedelta-like, default None] Left bound for generating timedeltas.
`end` [str or timedelta-like, default None] Right bound for generating timedeltas.
`periods` [int, default None] Number of periods to generate.
`freq` [str or DateOffset, default ‘D’] Frequency strings can have multiples, e.g. ‘5H’.
`name` [str, default None] Name of the resulting TimedeltaIndex.
`closed` [str, default None] Make the interval closed with respect to the given frequency to the
‘left’, ‘right’, or both sides (None).

Returns

`TimedeltaIndex`

Notes

Of the four parameters `start`, `end`, `periods`, and `freq`, exactly three must be specified. If `freq` is omitted, the resulting TimedeltaIndex will have periods linearly spaced elements between `start` and `end` (closed on both sides).

To learn more about the frequency strings, please see [this link](#).

Examples

```
>>> pd.timedelta_range(start='1 day', periods=4)
TimedeltaIndex(['1 days', '2 days', '3 days', '4 days'],
               dtype='timedelta64[ns]', freq='D')
```

The `closed` parameter specifies which endpoint is included. The default behavior is to include both endpoints.

```
>>> pd.timedelta_range(start='1 day', periods=4, closed='right')
TimedeltaIndex(['2 days', '3 days', '4 days'],
               dtype='timedelta64[ns]', freq='D')
```

The `freq` parameter specifies the frequency of the TimedeltaIndex. Only fixed frequencies can be passed, non-fixed frequencies such as ‘M’ (month end) will raise.

```
>>> pd.timedelta_range(start='1 day', end='2 days', freq='6H')
TimedeltaIndex(['1 days 00:00:00', '1 days 06:00:00', '1 days 12:00:00',
                '1 days 18:00:00', '2 days 00:00:00'],
               dtype='timedelta64[ns]', freq='6H')
```

Specify start, end, and periods; the frequency is generated automatically (linearly spaced).

```
>>> pd.timedelta_range(start='1 day', end='5 days', periods=4)
TimedeltaIndex(['1 days 00:00:00', '2 days 08:00:00', '3 days 16:00:00',
                 '5 days 00:00:00'],
                dtype='timedelta64[ns]', freq=None)
```

pandas.infer_freq

`pandas.infer_freq(index, warn=True)`

Infer the most likely frequency given the input index. If the frequency is uncertain, a warning will be printed.

Parameters

index [DatetimeIndex or TimedeltaIndex] If passed a Series will use the values of the series (NOT THE INDEX).

warn [bool, default True]

Returns

str or None None if no discernible frequency.

Raises

TypeError If the index is not datetime-like.

ValueError If there are fewer than three values.

Examples

```
>>> idx = pd.date_range(start='2020/12/01', end='2020/12/30', periods=30)
>>> pd.infer_freq(idx)
'D'
```

3.2.5 Top-level dealing with Interval data

`interval_range([start, end, periods, freq, ...])`

Return a fixed frequency IntervalIndex.

pandas.interval_range

`pandas.interval_range(start=None, end=None, periods=None, freq=None, name=None, closed='right')`
Return a fixed frequency IntervalIndex.

Parameters

start [numeric or datetime-like, default None] Left bound for generating intervals.

end [numeric or datetime-like, default None] Right bound for generating intervals.

periods [int, default None] Number of periods to generate.

freq [numeric, str, or DateOffset, default None] The length of each interval. Must be consistent with the type of start and end, e.g. 2 for numeric, or '5H' for datetime-like. Default is 1 for numeric and 'D' for datetime-like.

name [str, default None] Name of the resulting IntervalIndex.

closed [{‘left’, ‘right’, ‘both’, ‘neither’}, default ‘right’] Whether the intervals are closed on the left-side, right-side, both or neither.

Returns

IntervalIndex

See also:

IntervalIndex An Index of intervals that are all closed on the same side.

Notes

Of the four parameters `start`, `end`, `periods`, and `freq`, exactly three must be specified. If `freq` is omitted, the resulting `IntervalIndex` will have `periods` linearly spaced elements between `start` and `end`, inclusively.

To learn more about datetime-like frequency strings, please see [this link](#).

Examples

Numeric `start` and `end` is supported.

```
>>> pd.interval_range(start=0, end=5)
IntervalIndex([(0, 1], (1, 2], (2, 3], (3, 4], (4, 5]),
              dtype='interval[int64, right]')
```

Additionally, datetime-like input is also supported.

```
>>> pd.interval_range(start=pd.Timestamp('2017-01-01'),
...                     end=pd.Timestamp('2017-01-04'))
IntervalIndex([(2017-01-01, 2017-01-02], (2017-01-02, 2017-01-03],
               (2017-01-03, 2017-01-04]],
              dtype='interval[datetime64[ns], right]')
```

The `freq` parameter specifies the frequency between the left and right. endpoints of the individual intervals within the `IntervalIndex`. For numeric `start` and `end`, the frequency must also be numeric.

```
>>> pd.interval_range(start=0, periods=4, freq=1.5)
IntervalIndex([(0.0, 1.5], (1.5, 3.0], (3.0, 4.5], (4.5, 6.0]),
              dtype='interval[float64, right]')
```

Similarly, for datetime-like `start` and `end`, the frequency must be convertible to a `DateOffset`.

```
>>> pd.interval_range(start=pd.Timestamp('2017-01-01'),
...                     periods=3, freq='MS')
IntervalIndex([(2017-01-01, 2017-02-01], (2017-02-01, 2017-03-01],
               (2017-03-01, 2017-04-01]],
              dtype='interval[datetime64[ns], right]')
```

Specify `start`, `end`, and `periods`; the frequency is generated automatically (linearly spaced).

```
>>> pd.interval_range(start=0, end=6, periods=4)
IntervalIndex([(0.0, 1.5], (1.5, 3.0], (3.0, 4.5], (4.5, 6.0]),
              dtype='interval[float64, right]')
```

The `closed` parameter specifies which endpoints of the individual intervals within the `IntervalIndex` are closed.

```
>>> pd.interval_range(end=5, periods=4, closed='both')
IntervalIndex([[1, 2], [2, 3], [3, 4], [4, 5]],
              dtype='interval[int64, both]')
```

3.2.6 Top-level evaluation

<code>eval(expr[, parser, engine, truediv, ...])</code>	Evaluate a Python expression as a string using various backends.
---	--

pandas.eval

`pandas.eval(expr, parser='pandas', engine=None, truediv=NoDefault.no_default, local_dict=None, global_dict=None, resolvers=(), level=0, target=None, inplace=False)`

Evaluate a Python expression as a string using various backends.

The following arithmetic operations are supported: `+`, `-`, `*`, `/`, `**`, `%`, `//` (python engine only) along with the following boolean operations: `|` (or), `&` (and), and `~` (not). Additionally, the `'pandas'` parser allows the use of `and`, `or`, and `not` with the same semantics as the corresponding bitwise operators. `Series` and `DataFrame` objects are supported and behave as they would with plain ol' Python evaluation.

Parameters

expr [str] The expression to evaluate. This string cannot contain any Python `statements`, only Python `expressions`.

parser [{‘pandas’, ‘python’}, default ‘pandas’] The parser to use to construct the syntax tree from the expression. The default of ‘pandas’ parses code slightly different than standard Python. Alternatively, you can parse an expression using the ‘python’ parser to retain strict Python semantics. See the [enhancing performance](#) documentation for more details.

engine [{‘python’, ‘numexpr’}, default ‘numexpr’] The engine used to evaluate the expression. Supported engines are

- `None` : tries to use `numexpr`, falls back to `python`
- **‘numexpr’**: This default engine evaluates pandas objects using `numexpr` for large speed ups in complex expressions with large frames.
- **‘python’**: Performs operations as if you had eval’d in top level python. This engine is generally not that useful.

More backends may be available in the future.

truediv [bool, optional] Whether to use true division, like in Python ≥ 3 .

Deprecated since version 1.0.0.

local_dict [dict or None, optional] A dictionary of local variables, taken from `locals()` by default.

global_dict [dict or None, optional] A dictionary of global variables, taken from `globals()` by default.

resolvers [list of dict-like or None, optional] A list of objects implementing the `__getitem__` special method that you can use to inject an additional collection of namespaces to

use for variable lookup. For example, this is used in the `query()` method to inject the `DataFrame.index` and `DataFrame.columns` variables that refer to their respective `DataFrame` instance attributes.

level [int, optional] The number of prior stack frames to traverse and add to the current scope. Most users will **not** need to change this parameter.

target [object, optional, default None] This is the target object for assignment. It is used when there is variable assignment in the expression. If so, then *target* must support item assignment with string keys, and if a copy is being returned, it must also support `.copy()`.

inplace [bool, default False] If *target* is provided, and the expression mutates *target*, whether to modify *target* inplace. Otherwise, return a copy of *target* with the mutation.

Returns

ndarray, numeric scalar, DataFrame, Series, or None The completion value of evaluating the given code or None if `inplace=True`.

Raises

ValueError There are many instances where such an error can be raised:

- *target=None*, but the expression is multiline.
- The expression is multiline, but not all them have item assignment. An example of such an arrangement is this:

```
a = b + 1 a + 2
```

Here, there are expressions on different lines, making it multiline, but the last line has no variable assigned to the output of *a + 2*.

- *inplace=True*, but the expression is missing item assignment.
- Item assignment is provided, but the *target* does not support string item assignment.
- Item assignment is provided and *inplace=False*, but the *target* does not support the `.copy()` method

See also:

`DataFrame.query` Evaluates a boolean expression to query the columns of a frame.

`DataFrame.eval` Evaluate a string describing operations on DataFrame columns.

Notes

The `dtype` of any objects involved in an arithmetic % operation are recursively cast to `float64`.

See the *enhancing performance* documentation for more details.

Examples

```
>>> df = pd.DataFrame({"animal": ["dog", "pig"], "age": [10, 20]})  
>>> df  
animal  age  
0      dog    10  
1      pig    20
```

We can add a new column using `pd.eval`:

```
>>> pd.eval("double_age = df.age * 2", target=df)  
animal  age  double_age  
0      dog    10          20  
1      pig    20          40
```

3.2.7 Hashing

<code>util.hash_array(vals[, encoding, hash_key, ...])</code>	Given a 1d array, return an array of deterministic integers.
<code>util.hash_pandas_object(obj[, index, ...])</code>	Return a data hash of the Index/Series/DataFrame.

pandas.util.hash_array

`pandas.util.hash_array(vals, encoding='utf8', hash_key='0123456789123456', categorize=True)`
Given a 1d array, return an array of deterministic integers.

Parameters

vals [ndarray or ExtensionArray]
encoding [str, default ‘utf8’] Encoding for data & key when strings.
hash_key [str, default `_default_hash_key`] Hash_key for string key to encode.
categorize [bool, default True] Whether to first categorize object arrays before hashing. This is more efficient when the array contains duplicate values.

Returns

`ndarray[np.uint64, ndim=1]` Hashed values, same length as the vals.

pandas.util.hash_pandas_object

`pandas.util.hash_pandas_object(obj, index=True, encoding='utf8', hash_key='0123456789123456', categorize=True)`
Return a data hash of the Index/Series/DataFrame.

Parameters

obj [Index, Series, or DataFrame]
index [bool, default True] Include the index in the hash (if Series/DataFrame).
encoding [str, default ‘utf8’] Encoding for data & key when strings.
hash_key [str, default `_default_hash_key`] Hash_key for string key to encode.

categorize [bool, default True] Whether to first categorize object arrays before hashing. This is more efficient when the array contains duplicate values.

Returns

Series of uint64, same length as the object

3.2.8 Testing

`test([extra_args])`

Run the pandas test suite using pytest.

pandas.test

`pandas.test(extra_args=None)`

Run the pandas test suite using pytest.

3.3 Series

3.3.1 Constructor

`Series([data, index, dtype, name, copy, ...])`

One-dimensional ndarray with axis labels (including time series).

pandas.Series

`class pandas.Series(data=None, index=None, dtype=None, name=None, copy=False, fastpath=False)`

One-dimensional ndarray with axis labels (including time series).

Labels need not be unique but must be a hashable type. The object supports both integer- and label-based indexing and provides a host of methods for performing operations involving the index. Statistical methods from ndarray have been overridden to automatically exclude missing data (currently represented as NaN).

Operations between Series (+, -, /, *, **) align values based on their associated index values— they need not be the same length. The result index will be the sorted union of the two indexes.

Parameters

data [array-like, Iterable, dict, or scalar value] Contains data stored in Series. If data is a dict, argument order is maintained.

index [array-like or Index (1d)] Values must be hashable and have the same length as *data*. Non-unique index values are allowed. Will default to RangeIndex (0, 1, 2, ..., n) if not provided. If data is dict-like and index is None, then the keys in the data are used as the index. If the index is not None, the resulting Series is reindexed with the index values.

dtype [str, numpy.dtype, or ExtensionDtype, optional] Data type for the output Series. If not specified, this will be inferred from *data*. See the [user guide](#) for more usages.

name [str, optional] The name to give to the Series.

copy [bool, default False] Copy input data. Only affects Series or 1d ndarray input. See examples.

Examples

Constructing Series from a dictionary with an Index specified

```
>>> d = {'a': 1, 'b': 2, 'c': 3}
>>> ser = pd.Series(data=d, index=['a', 'b', 'c'])
>>> ser
a    1
b    2
c    3
dtype: int64
```

The keys of the dictionary match with the Index values, hence the Index values have no effect.

```
>>> d = {'a': 1, 'b': 2, 'c': 3}
>>> ser = pd.Series(data=d, index=['x', 'y', 'z'])
>>> ser
x    NaN
y    NaN
z    NaN
dtype: float64
```

Note that the Index is first build with the keys from the dictionary. After this the Series is reindexed with the given Index values, hence we get all NaN as a result.

Constructing Series from a list with *copy=False*.

```
>>> r = [1, 2]
>>> ser = pd.Series(r, copy=False)
>>> ser.iloc[0] = 999
>>> r
[1, 2]
>>> ser
0    999
1        2
dtype: int64
```

Due to input data type the Series has a *copy* of the original data even though *copy=False*, so the data is unchanged.

Constructing Series from a 1d ndarray with *copy=False*.

```
>>> r = np.array([1, 2])
>>> ser = pd.Series(r, copy=False)
>>> ser.iloc[0] = 999
>>> r
array([999,    2])
>>> ser
0    999
1        2
dtype: int64
```

Due to input data type the Series has a *view* on the original data, so the data is changed as well.

Attributes

<code>T</code>	Return the transpose, which is by definition self.
<code>array</code>	The ExtensionArray of the data backing this Series or Index.
<code>at</code>	Access a single value for a row/column label pair.
<code>attrs</code>	Dictionary of global attributes of this dataset.
<code>axes</code>	Return a list of the row axis labels.
<code>dtype</code>	Return the dtype object of the underlying data.
<code>dtypes</code>	Return the dtype object of the underlying data.
<code>flags</code>	Get the properties associated with this pandas object.
<code>hasnans</code>	Return True if there are any NaNs.
<code>iat</code>	Access a single value for a row/column pair by integer position.
<code>iloc</code>	Purely integer-location based indexing for selection by position.
<code>index</code>	The index (axis labels) of the Series.
<code>is_monotonic</code>	Return boolean if values in the object are monotonic_increasing.
<code>is_monotonic_decreasing</code>	Return boolean if values in the object are monotonic_decreasing.
<code>is_monotonic_increasing</code>	Alias for <code>is_monotonic</code> .
<code>is_unique</code>	Return boolean if values in the object are unique.
<code>loc</code>	Access a group of rows and columns by label(s) or a boolean array.
<code>name</code>	Return the name of the Series.
<code>nbytes</code>	Return the number of bytes in the underlying data.
<code>ndim</code>	Number of dimensions of the underlying data, by definition 1.
<code>shape</code>	Return a tuple of the shape of the underlying data.
<code>size</code>	Return the number of elements in the underlying data.
<code>values</code>	Return Series as ndarray or ndarray-like depending on the dtype.

pandas.Series.T

property Series.T

Return the transpose, which is by definition self.

pandas.Series.array

property Series.array

The ExtensionArray of the data backing this Series or Index.

Returns

ExtensionArray An ExtensionArray of the values stored within. For extension types, this is the actual array. For NumPy native types, this is a thin (no copy) wrapper around `numpy.ndarray`.

`.array` differs from `.values` which may require converting the data to a different form.

See also:

[`Index.to_numpy`](#) Similar method that always returns a NumPy array.

[`Series.to_numpy`](#) Similar method that always returns a NumPy array.

Notes

This table lays out the different array types for each extension dtype within pandas.

dtype	array type
category	Categorical
period	PeriodArray
interval	IntervalArray
IntegerNA	IntegerArray
string	StringArray
boolean	BooleanArray
datetime64[ns, tz]	DatetimeArray

For any 3rd-party extension types, the array type will be an ExtensionArray.

For all remaining dtypes .array will be a arrays.NumpyExtensionArray wrapping the actual ndarray stored within. If you absolutely need a NumPy array (possibly with copying / coercing data), then use [`Series.to_numpy\(\)`](#) instead.

Examples

For regular NumPy types like int, and float, a PandasArray is returned.

```
>>> pd.Series([1, 2, 3]).array
<PandasArray>
[1, 2, 3]
Length: 3, dtype: int64
```

For extension types, like Categorical, the actual ExtensionArray is returned

```
>>> ser = pd.Series(pd.Categorical(['a', 'b', 'a']))
>>> ser.array
['a', 'b', 'a']
Categories (2, object): ['a', 'b']
```

pandas.Series.at**property Series.at**

Access a single value for a row/column label pair.

Similar to loc, in that both provide label-based lookups. Use at if you only need to get or set a single value in a DataFrame or Series.

Raises

KeyError If ‘label’ does not exist in DataFrame.

See also:

DataFrame.iat Access a single value for a row/column pair by integer position.

DataFrame.loc Access a group of rows and columns by label(s).

Series.at Access a single value using a label.

Examples

```
>>> df = pd.DataFrame([[0, 2, 3], [0, 4, 1], [10, 20, 30]],  
...                      index=[4, 5, 6], columns=['A', 'B', 'C'])  
>>> df  
      A    B    C  
4    0    2    3  
5    0    4    1  
6   10   20   30
```

Get value at specified row/column pair

```
>>> df.at[4, 'B']  
2
```

Set value at specified row/column pair

```
>>> df.at[4, 'B'] = 10  
>>> df.at[4, 'B']  
10
```

Get value within a Series

```
>>> df.loc[5].at['B']  
4
```

pandas.Series.attrs

property Series.attrs

Dictionary of global attributes of this dataset.

Warning: attrs is experimental and may change without warning.

See also:

DataFrame.flags Global flags applying to this object.

pandas.Series.axes**property Series.axes**

Return a list of the row axis labels.

pandas.Series.dtype**property Series.dtype**

Return the dtype object of the underlying data.

pandas.Series.dtypes**property Series.dtypes**

Return the dtype object of the underlying data.

pandas.Series.flags**property Series.flags**

Get the properties associated with this pandas object.

The available flags are

- *Flags.allows_duplicate_labels*

See also:

[Flags](#) Flags that apply to pandas objects.

[DataFrame.attrs](#) Global metadata applying to this dataset.

Notes

“Flags” differ from “metadata”. Flags reflect properties of the pandas object (the Series or DataFrame). Metadata refer to properties of the dataset, and should be stored in [DataFrame.attrs](#).

Examples

```
>>> df = pd.DataFrame({"A": [1, 2]})  
>>> df.flags  
<Flags(allow_duplicates=True)>
```

Flags can be get or set using .

```
>>> df.flags.allow_duplicates  
True  
>>> df.flags.allow_duplicates = False
```

Or by slicing with a key

```
>>> df.flags["allows_duplicate_labels"]
False
>>> df.flags["allows_duplicate_labels"] = True
```

pandas.Series.hasnans

property Series.hasnans

Return True if there are any NaNs.

Enables various performance speedups.

pandas.Series.iat

property Series.iat

Access a single value for a row/column pair by integer position.

Similar to `iLoc`, in that both provide integer-based lookups. Use `iat` if you only need to get or set a single value in a DataFrame or Series.

Raises

`IndexError` When integer position is out of bounds.

See also:

`DataFrame.at` Access a single value for a row/column label pair.

`DataFrame.loc` Access a group of rows and columns by label(s).

`DataFrame.iloc` Access a group of rows and columns by integer position(s).

Examples

```
>>> df = pd.DataFrame([[0, 2, 3], [0, 4, 1], [10, 20, 30]],
...                      columns=['A', 'B', 'C'])
>>> df
   A    B    C
0  0    2    3
1  0    4    1
2  10   20   30
```

Get value at specified row/column pair

```
>>> df.iat[1, 2]
1
```

Set value at specified row/column pair

```
>>> df.iat[1, 2] = 10
>>> df.iat[1, 2]
10
```

Get value within a series

```
>>> df.loc[0].iat[1]
2
```

pandas.Series.iloc

property Series.iloc

Purely integer-location based indexing for selection by position.

.iloc[] is primarily integer position based (from 0 to length-1 of the axis), but may also be used with a boolean array.

Allowed inputs are:

- An integer, e.g. 5.
- A list or array of integers, e.g. [4, 3, 0].
- A slice object with ints, e.g. 1:7.
- A boolean array.
- A callable function with one argument (the calling Series or DataFrame) and that returns valid output for indexing (one of the above). This is useful in method chains, when you don't have a reference to the calling object, but would like to base your selection on some value.

.iloc will raise IndexError if a requested indexer is out-of-bounds, except slice indexers which allow out-of-bounds indexing (this conforms with python/numpy slice semantics).

See more at [Selection by Position](#).

See also:

[DataFrame.iat](#) Fast integer location scalar accessor.

[DataFrame.loc](#) Purely label-location based indexer for selection by label.

[Series.iloc](#) Purely integer-location based indexing for selection by position.

Examples

```
>>> mydict = [{‘a’: 1, ‘b’: 2, ‘c’: 3, ‘d’: 4},
...             {‘a’: 100, ‘b’: 200, ‘c’: 300, ‘d’: 400},
...             {‘a’: 1000, ‘b’: 2000, ‘c’: 3000, ‘d’: 4000}]
>>> df = pd.DataFrame(mydict)
>>> df
      a      b      c      d
0    1      2      3      4
1   100    200    300    400
2  1000   2000   3000   4000
```

Indexing just the rows

With a scalar integer.

```
>>> type(df.iloc[0])
<class ‘pandas.core.series.Series’>
>>> df.iloc[0]
```

(continues on next page)

(continued from previous page)

```
a    1
b    2
c    3
d    4
Name: 0, dtype: int64
```

With a list of integers.

```
>>> df.iloc[[0]]
   a   b   c   d
0  1  2  3  4
>>> type(df.iloc[[0]])
<class 'pandas.core.frame.DataFrame'>
```

```
>>> df.iloc[[0, 1]]
   a   b   c   d
0  1  2  3  4
1 100 200 300 400
```

With a *slice* object.

```
>>> df.iloc[:3]
   a   b   c   d
0  1  2  3  4
1 100 200 300 400
2 1000 2000 3000 4000
```

With a boolean mask the same length as the index.

```
>>> df.iloc[[True, False, True]]
   a   b   c   d
0  1  2  3  4
2 1000 2000 3000 4000
```

With a callable, useful in method chains. The *x* passed to the `lambda` is the DataFrame being sliced. This selects the rows whose index label even.

```
>>> df.iloc[lambda x: x.index % 2 == 0]
   a   b   c   d
0  1  2  3  4
2 1000 2000 3000 4000
```

Indexing both axes

You can mix the indexer types for the index and columns. Use `:` to select the entire axis.

With scalar integers.

```
>>> df.iloc[0, 1]
2
```

With lists of integers.

```
>>> df.iloc[[0, 2], [1, 3]]
      b      d
0    2     4
2  2000  4000
```

With *slice* objects.

```
>>> df.iloc[1:3, 0:3]
      a      b      c
1  100   200   300
2 1000  2000  3000
```

With a boolean array whose length matches the columns.

```
>>> df.iloc[:, [True, False, True, False]]
      a      c
0    1     3
1  100   300
2 1000  3000
```

With a callable function that expects the Series or DataFrame.

```
>>> df.iloc[:, lambda df: [0, 2]]
      a      c
0    1     3
1  100   300
2 1000  3000
```

pandas.Series.index

Series.index

The index (axis labels) of the Series.

pandas.Series.is_monotonic

property Series.is_monotonic

Return boolean if values in the object are monotonic_increasing.

Returns

bool

pandas.Series.is_monotonic_decreasing

property Series.is_monotonic_decreasing

Return boolean if values in the object are monotonic_decreasing.

Returns

bool

`pandas.Series.is_monotonic_increasing`

property `Series.is_monotonic_increasing`

Alias for `is_monotonic`.

`pandas.Series.is_unique`

property `Series.is_unique`

Return boolean if values in the object are unique.

Returns

`bool`

`pandas.Series.loc`

property `Series.loc`

Access a group of rows and columns by label(s) or a boolean array.

`.loc[]` is primarily label based, but may also be used with a boolean array.

Allowed inputs are:

- A single label, e.g. 5 or 'a', (note that 5 is interpreted as a *label* of the index, and **never** as an integer position along the index).
- A list or array of labels, e.g. ['a', 'b', 'c'].
- A slice object with labels, e.g. 'a':'f'.

Warning: Note that contrary to usual python slices, **both** the start and the stop are included

- A boolean array of the same length as the axis being sliced, e.g. [True, False, True].
- An alignable boolean Series. The index of the key will be aligned before masking.
- An alignable Index. The Index of the returned selection will be the input.
- A callable function with one argument (the calling Series or DataFrame) and that returns valid output for indexing (one of the above)

See more at [Selection by Label](#).

Raises

KeyError If any items are not found.

IndexingError If an indexed key is passed and its index is unalignable to the frame index.

See also:

[`DataFrame.at`](#) Access a single value for a row/column label pair.

[`DataFrame.iloc`](#) Access group of rows and columns by integer position(s).

[`DataFrame.xs`](#) Returns a cross-section (row(s) or column(s)) from the Series/DataFrame.

[`Series.loc`](#) Access group of values using labels.

Examples

Getting values

```
>>> df = pd.DataFrame([[1, 2], [4, 5], [7, 8]],
...                   index=['cobra', 'viper', 'sidewinder'],
...                   columns=['max_speed', 'shield'])
>>> df
      max_speed  shield
cobra          1        2
viper          4        5
sidewinder     7        8
```

Single label. Note this returns the row as a Series.

```
>>> df.loc['viper']
max_speed    4
shield       5
Name: viper, dtype: int64
```

List of labels. Note using [[]] returns a DataFrame.

```
>>> df.loc[['viper', 'sidewinder']]
      max_speed  shield
viper          4        5
sidewinder     7        8
```

Single label for row and column

```
>>> df.loc['cobra', 'shield']
2
```

Slice with labels for row and single label for column. As mentioned above, note that both the start and stop of the slice are included.

```
>>> df.loc['cobra':'viper', 'max_speed']
cobra    1
viper    4
Name: max_speed, dtype: int64
```

Boolean list with the same length as the row axis

```
>>> df.loc[[False, False, True]]
      max_speed  shield
sidewinder     7        8
```

Alignable boolean Series:

```
>>> df.loc[pd.Series([False, True, False],
...             index=['viper', 'sidewinder', 'cobra'])]
      max_speed  shield
sidewinder     7        8
```

Index (same behavior as `df.reindex`)

```
>>> df.loc[pd.Index(["cobra", "viper"], name="foo")]
          max_speed  shield
foo
cobra        1        2
viper        4        5
```

Conditional that returns a boolean Series

```
>>> df.loc[df['shield'] > 6]
          max_speed  shield
sidewinder      7        8
```

Conditional that returns a boolean Series with column labels specified

```
>>> df.loc[df['shield'] > 6, ['max_speed']]
          max_speed
sidewinder      7
```

Callable that returns a boolean Series

```
>>> df.loc[lambda df: df['shield'] == 8]
          max_speed  shield
sidewinder      7        8
```

Setting values

Set value for all items matching the list of labels

```
>>> df.loc[['viper', 'sidewinder'], ['shield']] = 50
>>> df
          max_speed  shield
cobra        1        2
viper        4      50
sidewinder      7      50
```

Set value for an entire row

```
>>> df.loc['cobra'] = 10
>>> df
          max_speed  shield
cobra       10       10
viper        4      50
sidewinder      7      50
```

Set value for an entire column

```
>>> df.loc[:, 'max_speed'] = 30
>>> df
          max_speed  shield
cobra       30       10
viper       30      50
sidewinder    30      50
```

Set value for rows matching callable condition

```
>>> df.loc[df['shield'] > 35] = 0
>>> df
      max_speed  shield
cobra            30     10
viper             0      0
sidewinder        0      0
```

Getting values on a DataFrame with an index that has integer labels

Another example using integers for the index

```
>>> df = pd.DataFrame([[1, 2], [4, 5], [7, 8]],
...                   index=[7, 8, 9], columns=['max_speed', 'shield'])
>>> df
      max_speed  shield
7              1      2
8              4      5
9              7      8
```

Slice with integer labels for rows. As mentioned above, note that both the start and stop of the slice are included.

```
>>> df.loc[7:9]
      max_speed  shield
7              1      2
8              4      5
9              7      8
```

Getting values with a MultiIndex

A number of examples using a DataFrame with a MultiIndex

```
>>> tuples = [
...     ('cobra', 'mark i'), ('cobra', 'mark ii'),
...     ('sidewinder', 'mark i'), ('sidewinder', 'mark ii'),
...     ('viper', 'mark ii'), ('viper', 'mark iii')
... ]
>>> index = pd.MultiIndex.from_tuples(tuples)
>>> values = [[12, 2], [0, 4], [10, 20],
...             [1, 4], [7, 1], [16, 36]]
>>> df = pd.DataFrame(values, columns=['max_speed', 'shield'], index=index)
>>> df
      max_speed  shield
cobra  mark i       12      2
           mark ii      0      4
sidewinder  mark i       10     20
           mark ii       1      4
viper    mark ii       7      1
           mark iii      16     36
```

Single label. Note this returns a DataFrame with a single index.

```
>>> df.loc['cobra']
      max_speed  shield
```

(continues on next page)

(continued from previous page)

mark i	12	2
mark ii	0	4

Single index tuple. Note this returns a Series.

```
>>> df.loc[('cobra', 'mark ii')]
max_speed    0
shield       4
Name: (cobra, mark ii), dtype: int64
```

Single label for row and column. Similar to passing in a tuple, this returns a Series.

```
>>> df.loc['cobra', 'mark i']
max_speed    12
shield       2
Name: (cobra, mark i), dtype: int64
```

Single tuple. Note using [[]] returns a DataFrame.

```
>>> df.loc[[('cobra', 'mark ii')]]
           max_speed  shield
cobra  mark ii      0        4
```

Single tuple for the index with a single label for the column

```
>>> df.loc[('cobra', 'mark i'), 'shield']
2
```

Slice from index tuple to single label

```
>>> df.loc[('cobra', 'mark i'):'viper']
           max_speed  shield
cobra  mark i      12        2
                  mark ii      0        4
sidewinder  mark i     10       20
                  mark ii      1        4
viper    mark ii      7         1
                  mark iii     16       36
```

Slice from index tuple to index tuple

```
>>> df.loc[('cobra', 'mark i'):(('viper', 'mark ii'))]
           max_speed  shield
cobra  mark i      12        2
                  mark ii      0        4
sidewinder  mark i     10       20
                  mark ii      1        4
viper    mark ii      7         1
```

pandas.Series.name**property Series.name**

Return the name of the Series.

The name of a Series becomes its index or column name if it is used to form a DataFrame. It is also used whenever displaying the Series using the interpreter.

Returns

label (hashable object) The name of the Series, also the column name if part of a DataFrame.

See also:

[**Series.rename**](#) Sets the Series name when given a scalar input.

[**Index.name**](#) Corresponding Index property.

Examples

The Series name can be set initially when calling the constructor.

```
>>> s = pd.Series([1, 2, 3], dtype=np.int64, name='Numbers')
>>> s
0    1
1    2
2    3
Name: Numbers, dtype: int64
>>> s.name = "Integers"
>>> s
0    1
1    2
2    3
Name: Integers, dtype: int64
```

The name of a Series within a DataFrame is its column name.

```
>>> df = pd.DataFrame([[1, 2], [3, 4], [5, 6]],
...                   columns=["Odd Numbers", "Even Numbers"])
>>> df
   Odd Numbers  Even Numbers
0            1            2
1            3            4
2            5            6
>>> df["Even Numbers"].name
'Even Numbers'
```

pandas.Series.nbytes

property Series.nbytes

Return the number of bytes in the underlying data.

pandas.Series.ndim

property Series.ndim

Number of dimensions of the underlying data, by definition 1.

pandas.Series.shape

property Series.shape

Return a tuple of the shape of the underlying data.

pandas.Series.size

property Series.size

Return the number of elements in the underlying data.

pandas.Series.values

property Series.values

Return Series as ndarray or ndarray-like depending on the dtype.

Warning: We recommend using `Series.array` or `Series.to_numpy()`, depending on whether you need a reference to the underlying data or a NumPy array.

Returns

`numpy.ndarray` or `ndarray-like`

See also:

`Series.array` Reference to the underlying data.

`Series.to_numpy` A NumPy array representing the underlying data.

Examples

```
>>> pd.Series([1, 2, 3]).values
array([1, 2, 3])
```

```
>>> pd.Series(list('aabc')).values
array(['a', 'a', 'b', 'c'], dtype=object)
```

```
>>> pd.Series(list('aabc')).astype('category').values
['a', 'a', 'b', 'c']
Categories (3, object): ['a', 'b', 'c']
```

Timezone aware datetime data is converted to UTC:

```
>>> pd.Series(pd.date_range('20130101', periods=3,
...                           tz='US/Eastern')).values
array(['2013-01-01T05:00:00.000000000',
       '2013-01-02T05:00:00.000000000',
       '2013-01-03T05:00:00.000000000'], dtype='datetime64[ns]')
```

empty

Methods

<code>abs()</code>	Return a Series/DataFrame with absolute numeric value of each element.
<code>add(other[, level, fill_value, axis])</code>	Return Addition of series and other, element-wise (binary operator <code>add</code>).
<code>add_prefix(prefix)</code>	Prefix labels with string <code>prefix</code> .
<code>add_suffix(suffix)</code>	Suffix labels with string <code>suffix</code> .
<code>agg([func, axis])</code>	Aggregate using one or more operations over the specified axis.
<code>aggregate([func, axis])</code>	Aggregate using one or more operations over the specified axis.
<code>align(other[, join, axis, level, copy, ...])</code>	Align two objects on their axes with the specified join method.
<code>all([axis, bool_only, skipna, level])</code>	Return whether all elements are True, potentially over an axis.
<code>any([axis, bool_only, skipna, level])</code>	Return whether any element is True, potentially over an axis.
<code>append(to_append[, ignore_index, ...])</code>	(DEPRECATED) Concatenate two or more Series.
<code>apply(func[, convert_dtype, args])</code>	Invoke function on values of Series.
<code>argmax([axis, skipna])</code>	Return int position of the largest value in the Series.
<code>argmin([axis, skipna])</code>	Return int position of the smallest value in the Series.
<code>argsort([axis, kind, order])</code>	Return the integer indices that would sort the Series values.
<code>asfreq(freq[, method, how, normalize, ...])</code>	Convert time series to specified frequency.
<code>asof(where[, subset])</code>	Return the last row(s) without any NaNs before <code>where</code> .
<code>astype(dtype[, copy, errors])</code>	Cast a pandas object to a specified dtype <code>dtype</code> .
<code>at_time(time[, asof, axis])</code>	Select values at particular time of day (e.g., 9:30AM).
<code>autocorr([lag])</code>	Compute the lag-N autocorrelation.
<code>backfill([axis, inplace, limit, downcast])</code>	Synonym for <code>DataFrame.fillna()</code> with <code>method='bfill'</code> .
<code>between(left, right[, inclusive])</code>	Return boolean Series equivalent to <code>left <= series <= right</code> .

continues on next page

Table 34 – continued from previous page

<code>between_time(start_time, end_time[, ...])</code>	Select values between particular times of the day (e.g., 9:00-9:30 AM).
<code>bfill([axis, inplace, limit, downcast])</code>	Synonym for <code>DataFrame.fillna()</code> with <code>method='bfill'</code> .
<code>bool()</code>	Return the bool of a single element Series or DataFrame.
<code>cat</code>	alias of <code>pandas.core.arrays.categorical.CategoricalAccessor</code>
<code>clip([lower, upper, axis, inplace])</code>	Trim values at input threshold(s).
<code>combine(other, func[, fill_value])</code>	Combine the Series with a Series or scalar according to <code>func</code> .
<code>combine_first(other)</code>	Update null elements with value in the same location in 'other'.
<code>compare(other[, align_axis, keep_shape, ...])</code>	Compare to another Series and show the differences.
<code>convert_dtypes([infer_objects, ...])</code>	Convert columns to best possible dtypes using dtypes supporting <code>pd.NA</code> .
<code>copy([deep])</code>	Make a copy of this object's indices and data.
<code>corr(other[, method, min_periods])</code>	Compute correlation with <code>other</code> Series, excluding missing values.
<code>count([level])</code>	Return number of non-NA/null observations in the Series.
<code>cov(other[, min_periods, ddof])</code>	Compute covariance with Series, excluding missing values.
<code>cummax([axis, skipna])</code>	Return cumulative maximum over a DataFrame or Series axis.
<code>cummin([axis, skipna])</code>	Return cumulative minimum over a DataFrame or Series axis.
<code>cumprod([axis, skipna])</code>	Return cumulative product over a DataFrame or Series axis.
<code>cumsum([axis, skipna])</code>	Return cumulative sum over a DataFrame or Series axis.
<code>describe([percentiles, include, exclude, ...])</code>	Generate descriptive statistics.
<code>diff([periods])</code>	First discrete difference of element.
<code>div(other[, level, fill_value, axis])</code>	Return Floating division of series and other, element-wise (binary operator <code>truediv</code>).
<code>divide(other[, level, fill_value, axis])</code>	Return Floating division of series and other, element-wise (binary operator <code>truediv</code>).
<code>divmod(other[, level, fill_value, axis])</code>	Return Integer division and modulo of series and other, element-wise (binary operator <code>divmod</code>).
<code>dot(other)</code>	Compute the dot product between the Series and the columns of other.
<code>drop([labels, axis, index, columns, level, ...])</code>	Return Series with specified index labels removed.
<code>drop_duplicates([keep, inplace])</code>	Return Series with duplicate values removed.
<code>droplevel(level[, axis])</code>	Return Series/DataFrame with requested index / column level(s) removed.
<code>dropna([axis, inplace, how])</code>	Return a new Series with missing values removed.
<code>dt</code>	alias of <code>pandas.core.indexes.accessors.CombinedDatetimelikeProperties</code>
<code>duplicated([keep])</code>	Indicate duplicate Series values.
<code>eq(other[, level, fill_value, axis])</code>	Return Equal to of series and other, element-wise (binary operator <code>eq</code>).

continues on next page

Table 34 – continued from previous page

<code>equals(other)</code>	Test whether two objects contain the same elements.
<code>ewm([com, span, halflife, alpha, ...])</code>	Provide exponentially weighted (EW) calculations.
<code>expanding([min_periods, center, axis, method])</code>	Provide expanding window calculations.
<code>explode([ignore_index])</code>	Transform each element of a list-like to a row.
<code>factorize([sort, na_sentinel])</code>	Encode the object as an enumerated type or categorical variable.
<code>ffill([axis, inplace, limit, downcast])</code>	Synonym for <code>DataFrame.fillna()</code> with <code>method='ffill'</code> .
<code>fillna([value, method, axis, inplace, ...])</code>	Fill NA/NaN values using the specified method.
<code>filter([items, like, regex, axis])</code>	Subset the dataframe rows or columns according to the specified index labels.
<code>first(offset)</code>	Select initial periods of time series data based on a date offset.
<code>first_valid_index()</code>	Return index for first non-NA value or None, if no non-NA value is found.
<code>floordiv(other[, level, fill_value, axis])</code>	Return Integer division of series and other, element-wise (binary operator <code>floordiv</code>).
<code>ge(other[, level, fill_value, axis])</code>	Return Greater than or equal to of series and other, element-wise (binary operator <code>ge</code>).
<code>get(key[, default])</code>	Get item from object for given key (ex: DataFrame column).
<code>groupby([by, axis, level, as_index, sort, ...])</code>	Group Series using a mapper or by a Series of columns.
<code>gt(other[, level, fill_value, axis])</code>	Return Greater than of series and other, element-wise (binary operator <code>gt</code>).
<code>head([n])</code>	Return the first <code>n</code> rows.
<code>hist([by, ax, grid, xlabelsize, xrot, ...])</code>	Draw histogram of the input series using matplotlib.
<code>idxmax([axis, skipna])</code>	Return the row label of the maximum value.
<code>idxmin([axis, skipna])</code>	Return the row label of the minimum value.
<code>infer_objects()</code>	Attempt to infer better dtypes for object columns.
<code>info([verbose, buf, max_cols, memory_usage, ...])</code>	Print a concise summary of a Series.
<code>interpolate([method, axis, limit, inplace, ...])</code>	Fill NaN values using an interpolation method.
<code>isin(values)</code>	Whether elements in Series are contained in <code>values</code> .
<code>isna()</code>	Detect missing values.
<code>isnull()</code>	Series.isnull is an alias for Series.isna.
<code>item()</code>	Return the first element of the underlying data as a Python scalar.
<code>items()</code>	Lazily iterate over (index, value) tuples.
<code>iteritems()</code>	Lazily iterate over (index, value) tuples.
<code>keys()</code>	Return alias for index.
<code>kurt([axis, skipna, level, numeric_only])</code>	Return unbiased kurtosis over requested axis.
<code>kurtosis([axis, skipna, level, numeric_only])</code>	Return unbiased kurtosis over requested axis.
<code>last(offset)</code>	Select final periods of time series data based on a date offset.
<code>last_valid_index()</code>	Return index for last non-NA value or None, if no non-NA value is found.
<code>le(other[, level, fill_value, axis])</code>	Return Less than or equal to of series and other, element-wise (binary operator <code>le</code>).
<code>lt(other[, level, fill_value, axis])</code>	Return Less than of series and other, element-wise (binary operator <code>lt</code>).

continues on next page

Table 34 – continued from previous page

<code>mad([axis, skipna, level])</code>	Return the mean absolute deviation of the values over the requested axis.
<code>map(arg[, na_action])</code>	Map values of Series according to an input mapping or function.
<code>mask(cond[, other, inplace, axis, level, ...])</code>	Replace values where the condition is True.
<code>max([axis, skipna, level, numeric_only])</code>	Return the maximum of the values over the requested axis.
<code>mean([axis, skipna, level, numeric_only])</code>	Return the mean of the values over the requested axis.
<code>median([axis, skipna, level, numeric_only])</code>	Return the median of the values over the requested axis.
<code>memory_usage([index, deep])</code>	Return the memory usage of the Series.
<code>min([axis, skipna, level, numeric_only])</code>	Return the minimum of the values over the requested axis.
<code>mod(other[, level, fill_value, axis])</code>	Return Modulo of series and other, element-wise (binary operator <i>mod</i>).
<code>mode([dropna])</code>	Return the mode(s) of the Series.
<code>mul(other[, level, fill_value, axis])</code>	Return Multiplication of series and other, element-wise (binary operator <i>mul</i>).
<code>multiply(other[, level, fill_value, axis])</code>	Return Multiplication of series and other, element-wise (binary operator <i>mul</i>).
<code>ne(other[, level, fill_value, axis])</code>	Return Not equal to of series and other, element-wise (binary operator <i>ne</i>).
<code>nlargest([n, keep])</code>	Return the largest <i>n</i> elements.
<code>notna()</code>	Detect existing (non-missing) values.
<code>notnull()</code>	Series.notnull is an alias for Series.notna.
<code>nsmallest([n, keep])</code>	Return the smallest <i>n</i> elements.
<code>nunique([dropna])</code>	Return number of unique elements in the object.
<code>pad([axis, inplace, limit, downcast])</code>	Synonym for <code>DataFrame.fillna()</code> with <code>method='ffill'</code> .
<code>pct_change([periods, fill_method, limit, freq])</code>	Percentage change between the current and a prior element.
<code>pipe(func, *args, **kwargs)</code>	Apply chainable functions that expect Series or DataFrames.
<code>plot</code>	alias of <code>pandas.plotting._core.PlotAccessor</code>
<code>pop(item)</code>	Return item and drops from series.
<code>pow(other[, level, fill_value, axis])</code>	Return Exponential power of series and other, element-wise (binary operator <i>pow</i>).
<code>prod([axis, skipna, level, numeric_only, ...])</code>	Return the product of the values over the requested axis.
<code>product([axis, skipna, level, numeric_only, ...])</code>	Return the product of the values over the requested axis.
<code>quantile([q, interpolation])</code>	Return value at the given quantile.
<code>radd(other[, level, fill_value, axis])</code>	Return Addition of series and other, element-wise (binary operator <i>radd</i>).
<code>rank([axis, method, numeric_only, ...])</code>	Compute numerical data ranks (1 through n) along axis.
<code>ravel([order])</code>	Return the flattened underlying data as an ndarray.
<code>rdiv(other[, level, fill_value, axis])</code>	Return Floating division of series and other, element-wise (binary operator <i>rtruediv</i>).
<code>rdivmod(other[, level, fill_value, axis])</code>	Return Integer division and modulo of series and other, element-wise (binary operator <i>rdivmod</i>).

continues on next page

Table 34 – continued from previous page

<code>reindex(*args, **kwargs)</code>	Conform Series to new index with optional filling logic.
<code>reindex_like(other[, method, copy, limit, ...])</code>	Return an object with matching indices as other object.
<code>rename([index, axis, copy, inplace, level, ...])</code>	Alter Series index labels or name.
<code>rename_axis([mapper, index, columns, axis, ...])</code>	Set the name of the axis for the index or columns.
<code>reorder_levels(order)</code>	Rearrange index levels using input order.
<code>repeat(repeats[, axis])</code>	Repeat elements of a Series.
<code>replace([to_replace, value, inplace, limit, ...])</code>	Replace values given in <code>to_replace</code> with <code>value</code> .
<code>resample(rule[, axis, closed, label, ...])</code>	Resample time-series data.
<code>reset_index([level, drop, name, inplace])</code>	Generate a new DataFrame or Series with the index reset.
<code>rfloordiv(other[, level, fill_value, axis])</code>	Return Integer division of series and other, element-wise (binary operator <code>rfloordiv</code>).
<code>rmod(other[, level, fill_value, axis])</code>	Return Modulo of series and other, element-wise (binary operator <code>rmod</code>).
<code>rmul(other[, level, fill_value, axis])</code>	Return Multiplication of series and other, element-wise (binary operator <code>rmul</code>).
<code>rolling(window[, min_periods, center, ...])</code>	Provide rolling window calculations.
<code>round([decimals])</code>	Round each value in a Series to the given number of decimals.
<code>rpow(other[, level, fill_value, axis])</code>	Return Exponential power of series and other, element-wise (binary operator <code>rpow</code>).
<code>rsub(other[, level, fill_value, axis])</code>	Return Subtraction of series and other, element-wise (binary operator <code>rsub</code>).
<code>rtruediv(other[, level, fill_value, axis])</code>	Return Floating division of series and other, element-wise (binary operator <code>rtruediv</code>).
<code>sample([n, frac, replace, weights, ...])</code>	Return a random sample of items from an axis of object.
<code>searchsorted(value[, side, sorter])</code>	Find indices where elements should be inserted to maintain order.
<code>sem([axis, skipna, level, ddof, numeric_only])</code>	Return unbiased standard error of the mean over requested axis.
<code>set_axis(labels[, axis, inplace])</code>	Assign desired index to given axis.
<code>set_flags(*[, copy, allows_duplicate_labels])</code>	Return a new object with updated flags.
<code>shift([periods, freq, axis, fill_value])</code>	Shift index by desired number of periods with an optional time <code>freq</code> .
<code>skew([axis, skipna, level, numeric_only])</code>	Return unbiased skew over requested axis.
<code>slice_shift([periods, axis])</code>	(DEPRECATED) Equivalent to <code>shift</code> without copying data.
<code>sort_index([axis, level, ascending, ...])</code>	Sort Series by index labels.
<code>sort_values([axis, ascending, inplace, ...])</code>	Sort by the values.
<code>sparse</code>	alias of <code>pandas.core.arrays.sparse.accessor.SparseAccessor</code>
<code>squeeze([axis])</code>	Squeeze 1 dimensional axis objects into scalars.
<code>std([axis, skipna, level, ddof, numeric_only])</code>	Return sample standard deviation over requested axis.
<code>str</code>	alias of <code>pandas.core.strings.accessor.StringMethods</code>
<code>sub(other[, level, fill_value, axis])</code>	Return Subtraction of series and other, element-wise (binary operator <code>sub</code>).

continues on next page

Table 34 – continued from previous page

<code>subtract</code> (other[, level, fill_value, axis])	Return Subtraction of series and other, element-wise (binary operator <code>sub</code>).
<code>sum</code> ([axis, skipna, level, numeric_only, ...])	Return the sum of the values over the requested axis.
<code>swapaxes</code> (axis1, axis2[, copy])	Interchange axes and swap values axes appropriately.
<code>swaplevel</code> ([i, j, copy])	Swap levels i and j in a <code>MultiIndex</code> .
<code>tail</code> ([n])	Return the last n rows.
<code>take</code> (indices[, axis, is_copy])	Return the elements in the given <i>positional</i> indices along an axis.
<code>to_clipboard</code> ([excel, sep])	Copy object to the system clipboard.
<code>to_csv</code> ([path_or_buf, sep, na_rep, ...])	Write object to a comma-separated values (csv) file.
<code>to_dict</code> ([into])	Convert Series to {label -> value} dict or dict-like object.
<code>to_excel</code> (excel_writer[, sheet_name, na_rep, ...])	Write object to an Excel sheet.
<code>to_frame</code> ([name])	Convert Series to DataFrame.
<code>to_hdf</code> (path_or_buf, key[, mode, complevel, ...])	Write the contained data to an HDF5 file using HDFStore.
<code>to_json</code> ([path_or_buf, orient, date_format, ...])	Convert the object to a JSON string.
<code>to_latex</code> ([buf, columns, col_space, header, ...])	Render object to a LaTeX tabular, longtable, or nested table.
<code>to_list</code> ()	Return a list of the values.
<code>to_markdown</code> ([buf, mode, index, storage_options])	Print Series in Markdown-friendly format.
<code>to_numpy</code> ([dtype, copy, na_value])	A NumPy ndarray representing the values in this Series or Index.
<code>to_period</code> ([freq, copy])	Convert Series from DatetimeIndex to PeriodIndex.
<code>to_pickle</code> (path[, compression, protocol, ...])	Pickle (serialize) object to file.
<code>to_sql</code> (name, con[, schema, if_exists, ...])	Write records stored in a DataFrame to a SQL database.
<code>to_string</code> ([buf, na_rep, float_format, ...])	Render a string representation of the Series.
<code>to_timestamp</code> ([freq, how, copy])	Cast to DatetimeIndex of Timestamps, at <i>beginning</i> of period.
<code>to_xarray</code> ()	Return an xarray object from the pandas object.
<code>tolist</code> ()	Return a list of the values.
<code>transform</code> (func[, axis])	Call func on self producing a Series with the same axis shape as self.
<code>transpose</code> (*args, **kwargs)	Return the transpose, which is by definition self.
<code>truediv</code> (other[, level, fill_value, axis])	Return Floating division of series and other, element-wise (binary operator <code>truediv</code>).
<code>truncate</code> ([before, after, axis, copy])	Truncate a Series or DataFrame before and after some index value.
<code>tshift</code> ([periods, freq, axis])	(DEPRECATED) Shift the time index, using the index's frequency if available.
<code>tz_convert</code> (tz[, axis, level, copy])	Convert tz-aware axis to target time zone.
<code>tz_localize</code> (tz[, axis, level, copy, ...])	Localize tz-naive index of a Series or DataFrame to target time zone.
<code>unique</code> ()	Return unique values of Series object.
<code>unstack</code> ([level, fill_value])	Unstack, also known as pivot, Series with MultiIndex to produce DataFrame.
<code>update</code> (other)	Modify Series in place using values from passed Series.
<code>value_counts</code> ([normalize, sort, ascending, ...])	Return a Series containing counts of unique values.
<code>var</code> ([axis, skipna, level, ddof, numeric_only])	Return unbiased variance over requested axis.

continues on next page

Table 34 – continued from previous page

<code>view([dtype])</code>	Create a new view of the Series.
<code>where(cond[, other, inplace, axis, level, ...])</code>	Replace values where the condition is False.
<code>xs(key[, axis, level, drop_level])</code>	Return cross-section from the Series/DataFrame.

pandas.Series.abs

Series.abs()

Return a Series/DataFrame with absolute numeric value of each element.

This function only applies to elements that are all numeric.

Returns

`abs` Series/DataFrame containing the absolute value of each element.

See also:

[numpy.absolute](#) Calculate the absolute value element-wise.

Notes

For complex inputs, $1.2 + 1j$, the absolute value is $\sqrt{a^2 + b^2}$.

Examples

Absolute numeric values in a Series.

```
>>> s = pd.Series([-1.10, 2, -3.33, 4])
>>> s.abs()
0    1.10
1    2.00
2    3.33
3    4.00
dtype: float64
```

Absolute numeric values in a Series with complex numbers.

```
>>> s = pd.Series([1.2 + 1j])
>>> s.abs()
0    1.56205
dtype: float64
```

Absolute numeric values in a Series with a Timedelta element.

```
>>> s = pd.Series([pd.Timedelta('1 days')])
>>> s.abs()
0    1 days
dtype: timedelta64[ns]
```

Select rows with data closest to certain value using argsort (from StackOverflow).

```
>>> df = pd.DataFrame({  
...     'a': [4, 5, 6, 7],  
...     'b': [10, 20, 30, 40],  
...     'c': [100, 50, -30, -50]  
... })  
>>> df  
   a    b    c  
0  4   10  100  
1  5   20   50  
2  6   30  -30  
3  7   40  -50  
>>> df.loc[(df.c - 43).abs().argsort()]  
   a    b    c  
1  5   20   50  
0  4   10  100  
2  6   30  -30  
3  7   40  -50
```

pandas.Series.add

`Series.add(other, level=None, fill_value=None, axis=0)`

Return Addition of series and other, element-wise (binary operator *add*).

Equivalent to `series + other`, but with support to substitute a `fill_value` for missing data in either one of the inputs.

Parameters

other [Series or scalar value]

fill_value [None or float value, default None (NaN)] Fill existing missing (NaN) values, and any new element needed for successful Series alignment, with this value before computation. If data in both corresponding Series locations is missing the result of filling (at that location) will be missing.

level [int or name] Broadcast across a level, matching Index values on the passed Multi-Index level.

Returns

`Series` The result of the operation.

See also:

`Series.radd` Reverse of the Addition operator, see Python documentation for more details.

Examples

```
>>> a = pd.Series([1, 1, 1, np.nan], index=['a', 'b', 'c', 'd'])
>>> a
a    1.0
b    1.0
c    1.0
d    NaN
dtype: float64
>>> b = pd.Series([1, np.nan, 1, np.nan], index=['a', 'b', 'd', 'e'])
>>> b
a    1.0
b    NaN
d    1.0
e    NaN
dtype: float64
>>> a.add(b, fill_value=0)
a    2.0
b    1.0
c    1.0
d    1.0
e    NaN
dtype: float64
```

[pandas.Series.add_prefix](#)

`Series.add_prefix(prefix)`

Prefix labels with string *prefix*.

For Series, the row labels are prefixed. For DataFrame, the column labels are prefixed.

Parameters

`prefix` [str] The string to add before each label.

Returns

`Series or DataFrame` New Series or DataFrame with updated labels.

See also:

`Series.add_suffix` Suffix row labels with string *suffix*.

`DataFrame.add_suffix` Suffix column labels with string *suffix*.

Examples

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s
0    1
1    2
2    3
3    4
dtype: int64
```

```
>>> s.add_prefix('item_')
item_0    1
item_1    2
item_2    3
item_3    4
dtype: int64
```

```
>>> df = pd.DataFrame({'A': [1, 2, 3, 4], 'B': [3, 4, 5, 6]})  
>>> df  
   A  B  
0  1  3  
1  2  4  
2  3  5  
3  4  6
```

```
>>> df.add_prefix('col_')
   col_A  col_B
0      1      3
1      2      4
2      3      5
3      4      6
```

pandas.Series.add_suffix

`Series.add_suffix(suffix)`

Suffix labels with string *suffix*.

For Series, the row labels are suffixed. For DataFrame, the column labels are suffixed.

Parameters

`suffix` [str] The string to add after each label.

Returns

`Series or DataFrame` New Series or DataFrame with updated labels.

See also:

`Series.add_prefix` Prefix row labels with string *prefix*.

`DataFrame.add_prefix` Prefix column labels with string *prefix*.

Examples

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s
0    1
1    2
2    3
3    4
dtype: int64
```

```
>>> s.add_suffix('_item')
0_item    1
1_item    2
2_item    3
3_item    4
dtype: int64
```

```
>>> df = pd.DataFrame({'A': [1, 2, 3, 4], 'B': [3, 4, 5, 6]})
>>> df
   A   B
0  1  3
1  2  4
2  3  5
3  4  6
```

```
>>> df.add_suffix('_col')
      A_col  B_col
0         1      3
1         2      4
2         3      5
3         4      6
```

pandas.Series.agg

`Series.agg(func=None, axis=0, *args, **kwargs)`

Aggregate using one or more operations over the specified axis.

Parameters

func [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a Series or when passed to Series.apply.

Accepted combinations are:

- function
- string function name
- list of functions and/or function names, e.g. [np.sum, 'mean']
- dict of axis labels -> functions, function names or list of such.

axis [{0 or 'index'}] Parameter needed for compatibility with DataFrame.

***args** Positional arguments to pass to *func*.

****kwargs** Keyword arguments to pass to *func*.

Returns

scalar, Series or DataFrame The return can be:

- scalar : when Series.agg is called with single function
- Series : when DataFrame.agg is called with a single function
- DataFrame : when DataFrame.agg is called with several functions

Return scalar, Series or DataFrame.

See also:

`Series.apply` Invoke function on a Series.

`Series.transform` Transform function producing a Series with like indexes.

Notes

`agg` is an alias for `aggregate`. Use the alias.

Functions that mutate the passed object can produce unexpected behavior or errors and are not supported. See [Mutating with User Defined Function \(UDF\) methods](#) for more details.

A passed user-defined-function will be passed a Series for evaluation.

Examples

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s
0    1
1    2
2    3
3    4
dtype: int64
```

```
>>> s.agg('min')
1
```

```
>>> s.agg(['min', 'max'])
min    1
max    4
dtype: int64
```

pandas.Series.aggregate

`Series.aggregate(func=None, axis=0, *args, **kwargs)`

Aggregate using one or more operations over the specified axis.

Parameters

`func` [function, str, list or dict] Function to use for aggregating the data. If a function, must either work when passed a Series or when passed to Series.apply.

Accepted combinations are:

- function
- string function name
- list of functions and/or function names, e.g. [`np.sum`, 'mean']
- dict of axis labels -> functions, function names or list of such.

`axis` [{0 or 'index'}] Parameter needed for compatibility with DataFrame.

`*args` Positional arguments to pass to `func`.

****kwargs** Keyword arguments to pass to *func*.

Returns

scalar, Series or DataFrame The return can be:

- scalar : when Series.agg is called with single function
- Series : when DataFrame.agg is called with a single function
- DataFrame : when DataFrame.agg is called with several functions

Return scalar, Series or DataFrame.

See also:

[`Series.apply`](#) Invoke function on a Series.

[`Series.transform`](#) Transform function producing a Series with like indexes.

Notes

agg is an alias for *aggregate*. Use the alias.

Functions that mutate the passed object can produce unexpected behavior or errors and are not supported. See [Mutating with User Defined Function \(UDF\) methods](#) for more details.

A passed user-defined-function will be passed a Series for evaluation.

Examples

```
>>> s = pd.Series([1, 2, 3, 4])
>>> s
0    1
1    2
2    3
3    4
dtype: int64
```

```
>>> s.agg('min')
1
```

```
>>> s.agg(['min', 'max'])
min    1
max    4
dtype: int64
```

pandas.Series.align

```
Series.align(other, join='outer', axis=None, level=None, copy=True, fill_value=None, method=None,
            limit=None, fill_axis=0, broadcast_axis=None)
```

Align two objects on their axes with the specified join method.

Join method is specified for each axis Index.

Parameters

other [DataFrame or Series]

join [{‘outer’, ‘inner’, ‘left’, ‘right’}], default ‘outer’]

axis [allowed axis of the other object, default None] Align on index (0), columns (1), or both (None).

level [int or level name, default None] Broadcast across a level, matching Index values on the passed MultiIndex level.

copy [bool, default True] Always returns new objects. If copy=False and no reindexing is required then original objects are returned.

fill_value [scalar, default np.NaN] Value to use for missing values. Defaults to NaN, but can be any “compatible” value.

method [{‘backfill’, ‘bfill’, ‘pad’, ‘ffill’, None}, default None] Method to use for filling holes in reindexed Series:

- pad / ffill: propagate last valid observation forward to next valid.
- backfill / bfill: use NEXT valid observation to fill gap.

limit [int, default None] If method is specified, this is the maximum number of consecutive NaN values to forward/backward fill. In other words, if there is a gap with more than this number of consecutive NaNs, it will only be partially filled. If method is not specified, this is the maximum number of entries along the entire axis where NaNs will be filled. Must be greater than 0 if not None.

fill_axis [{0 or ‘index’}], default 0] Filling axis, method and limit.

broadcast_axis [{0 or ‘index’}], default None] Broadcast values along this axis, if aligning two objects of different dimensions.

Returns

(left, right) [(Series, type of other)] Aligned objects.

Examples

```
>>> df = pd.DataFrame(
...     [[1, 2, 3, 4], [6, 7, 8, 9]], columns=["D", "B", "E", "A"], index=[1, 2]
... )
>>> other = pd.DataFrame(
...     [[10, 20, 30, 40], [60, 70, 80, 90], [600, 700, 800, 900]],
...     columns=["A", "B", "C", "D"],
...     index=[2, 3, 4],
... )
>>> df
```

(continues on next page)

(continued from previous page)

	D	B	E	A
1	1	2	3	4
2	6	7	8	9

	>>> other			
	A	B	C	D
2	10	20	30	40
3	60	70	80	90
4	600	700	800	900

Align on columns:

	>>> left, right = df.align(other, join="outer", axis=1)				
	>>> left				
	A	B	C	D	E
1	4	2	NaN	1	3
2	9	7	NaN	6	8

	>>> right				
	A	B	C	D	E
2	10	20	30	40	NaN
3	60	70	80	90	NaN
4	600	700	800	900	NaN

We can also align on the index:

	>>> left, right = df.align(other, join="outer", axis=0)				
	>>> left				
	D	B	E	A	
1	1.0	2.0	3.0	4.0	
2	6.0	7.0	8.0	9.0	
3	NaN	NaN	NaN	NaN	
4	NaN	NaN	NaN	NaN	

	>>> right				
	A	B	C	D	
1	NaN	NaN	NaN	NaN	
2	10.0	20.0	30.0	40.0	
3	60.0	70.0	80.0	90.0	
4	600.0	700.0	800.0	900.0	

Finally, the default `axis=None` will align on both index and columns:

	>>> left, right = df.align(other, join="outer", axis=None)				
	>>> left				
	A	B	C	D	E
1	4.0	2.0	NaN	1.0	3.0
2	9.0	7.0	NaN	6.0	8.0
3	NaN	NaN	NaN	NaN	NaN
4	NaN	NaN	NaN	NaN	NaN

	>>> right				
	A	B	C	D	E
1	NaN	NaN	NaN	NaN	NaN
2	10.0	20.0	30.0	40.0	NaN
3	60.0	70.0	80.0	90.0	NaN
4	600.0	700.0	800.0	900.0	NaN

pandas.Series.all

`Series.all(axis=0, bool_only=None, skipna=True, level=None, **kwargs)`

Return whether all elements are True, potentially over an axis.

Returns True unless there at least one element within a series or along a Dataframe axis that is False or equivalent (e.g. zero or empty).

Parameters

axis [{0 or ‘index’, 1 or ‘columns’, None}, default 0] Indicate which axis or axes should be reduced.

- 0 / ‘index’ : reduce the index, return a Series whose index is the original column labels.
- 1 / ‘columns’ : reduce the columns, return a Series whose index is the original index.
- None : reduce all axes, return a scalar.

bool_only [bool, default None] Include only boolean columns. If None, will attempt to use everything, then use only boolean data. Not implemented for Series.

skipna [bool, default True] Exclude NA/null values. If the entire row/column is NA and skipna is True, then the result will be True, as for an empty row/column. If skipna is False, then NA are treated as True, because these are not equal to zero.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

****kwargs** [any, default None] Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

scalar or Series If level is specified, then, Series is returned; otherwise, scalar is returned.

See also:

`Series.all` Return True if all elements are True.

`DataFrame.any` Return True if one (or more) elements are True.

Examples

Series

```
>>> pd.Series([True, True]).all()
True
>>> pd.Series([True, False]).all()
False
>>> pd.Series([], dtype="float64").all()
True
>>> pd.Series([np.nan]).all()
True
>>> pd.Series([np.nan]).all(skipna=False)
True
```

DataFrames

Create a dataframe from a dictionary.

```
>>> df = pd.DataFrame({'col1': [True, True], 'col2': [True, False]})  
>>> df  
      col1    col2  
0   True    True  
1   True   False
```

Default behaviour checks if column-wise values all return True.

```
>>> df.all()  
col1    True  
col2   False  
dtype: bool
```

Specify `axis='columns'` to check if row-wise values all return True.

```
>>> df.all(axis='columns')  
0    True  
1   False  
dtype: bool
```

Or `axis=None` for whether every value is True.

```
>>> df.all(axis=None)  
False
```

pandas.Series.any

`Series.any(axis=0, bool_only=None, skipna=True, level=None, **kwargs)`

Return whether any element is True, potentially over an axis.

Returns False unless there is at least one element within a series or along a Dataframe axis that is True or equivalent (e.g. non-zero or non-empty).

Parameters

axis [{0 or ‘index’, 1 or ‘columns’, None}, default 0] Indicate which axis or axes should be reduced.

- 0 / ‘index’ : reduce the index, return a Series whose index is the original column labels.
- 1 / ‘columns’ : reduce the columns, return a Series whose index is the original index.
- None : reduce all axes, return a scalar.

bool_only [bool, default None] Include only boolean columns. If None, will attempt to use everything, then use only boolean data. Not implemented for Series.

skipna [bool, default True] Exclude NA/null values. If the entire row/column is NA and skipna is True, then the result will be False, as for an empty row/column. If skipna is False, then NA are treated as True, because these are not equal to zero.

level [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a scalar.

****kwargs** [any, default None] Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

scalar or Series If level is specified, then, Series is returned; otherwise, scalar is returned.

See also:

[numpy.any](#) Numpy version of this method.

[Series.any](#) Return whether any element is True.

[Series.all](#) Return whether all elements are True.

[DataFrame.any](#) Return whether any element is True over requested axis.

[DataFrame.all](#) Return whether all elements are True over requested axis.

Examples

Series

For Series input, the output is a scalar indicating whether any element is True.

```
>>> pd.Series([False, False]).any()
False
>>> pd.Series([True, False]).any()
True
>>> pd.Series([], dtype="float64").any()
False
>>> pd.Series([np.nan]).any()
False
>>> pd.Series([np.nan]).any(skipna=False)
True
```

DataFrame

Whether each column contains at least one True element (the default).

```
>>> df = pd.DataFrame({ "A": [1, 2], "B": [0, 2], "C": [0, 0] })
>>> df
   A  B  C
0  1  0  0
1  2  2  0
```

```
>>> df.any()
A    True
B    True
C   False
dtype: bool
```

Aggregating over the columns.

```
>>> df = pd.DataFrame({ "A": [True, False], "B": [1, 2] })
>>> df
     A  B
0  True  1
1 False  2
```

```
>>> df.any(axis='columns')
0    True
1    True
dtype: bool
```

```
>>> df = pd.DataFrame({"A": [True, False], "B": [1, 0]})
>>> df
   A   B
0  1  1
1  0  0
```

```
>>> df.any(axis='columns')
0    True
1    False
dtype: bool
```

Aggregating over the entire DataFrame with `axis=None`.

```
>>> df.any(axis=None)
True
```

`any` for an empty DataFrame is an empty Series.

```
>>> pd.DataFrame([]).any()
Series([], dtype: bool)
```

pandas.Series.append

`Series.append(to_append, ignore_index=False, verify_integrity=False)`
Concatenate two or more Series.

Deprecated since version 1.4.0: Use `concat()` instead. For further details see [Deprecated DataFrame.append and Series.append](#)

Parameters

`to_append` [Series or list/tuple of Series] Series to append with self.

`ignore_index` [bool, default False] If True, the resulting axis will be labeled 0, 1, ..., n - 1.

`verify_integrity` [bool, default False] If True, raise Exception on creating index with duplicates.

Returns

`Series` Concatenated Series.

See also:

`concat` General function to concatenate DataFrame or Series objects.

Notes

Iteratively appending to a Series can be more computationally intensive than a single concatenate. A better solution is to append values to a list and then concatenate the list with the original Series all at once.

Examples

```
>>> s1 = pd.Series([1, 2, 3])
>>> s2 = pd.Series([4, 5, 6])
>>> s3 = pd.Series([4, 5, 6], index=[3, 4, 5])
>>> s1.append(s2)
0    1
1    2
2    3
0    4
1    5
2    6
dtype: int64
```

```
>>> s1.append(s3)
0    1
1    2
2    3
3    4
4    5
5    6
dtype: int64
```

With *ignore_index* set to True:

```
>>> s1.append(s2, ignore_index=True)
0    1
1    2
2    3
3    4
4    5
5    6
dtype: int64
```

With *verify_integrity* set to True:

```
>>> s1.append(s2, verify_integrity=True)
Traceback (most recent call last):
...
ValueError: Indexes have overlapping values: [0, 1, 2]
```

pandas.Series.apply

`Series.apply(func, convert_dtype=True, args=(), **kwargs)`

Invoke function on values of Series.

Can be ufunc (a NumPy function that applies to the entire Series) or a Python function that only works on single values.

Parameters

`func` [function] Python function or NumPy ufunc to apply.

`convert_dtype` [bool, default True] Try to find better dtype for elementwise function results. If False, leave as dtype=object. Note that the dtype is always preserved for some extension array dtypes, such as Categorical.

`args` [tuple] Positional arguments passed to func after the series value.

`**kwargs` Additional keyword arguments passed to func.

Returns

`Series or DataFrame` If func returns a Series object the result will be a DataFrame.

See also:

`Series.map` For element-wise operations.

`Series.agg` Only perform aggregating type operations.

`Series.transform` Only perform transforming type operations.

Notes

Functions that mutate the passed object can produce unexpected behavior or errors and are not supported. See [Mutating with User Defined Function \(UDF\) methods](#) for more details.

Examples

Create a series with typical summer temperatures for each city.

```
>>> s = pd.Series([20, 21, 12],
...                 index=['London', 'New York', 'Helsinki'])
>>> s
London    20
New York  21
Helsinki  12
dtype: int64
```

Square the values by defining a function and passing it as an argument to `apply()`.

```
>>> def square(x):
...     return x ** 2
>>> s.apply(square)
London    400
New York  441
Helsinki 144
dtype: int64
```

Square the values by passing an anonymous function as an argument to `apply()`.

```
>>> s.apply(lambda x: x ** 2)
London      400
New York    441
Helsinki   144
dtype: int64
```

Define a custom function that needs additional positional arguments and pass these additional arguments using the `args` keyword.

```
>>> def subtract_custom_value(x, custom_value):
...     return x - custom_value
```

```
>>> s.apply(subtract_custom_value, args=(5,))
London      15
New York    16
Helsinki   7
dtype: int64
```

Define a custom function that takes keyword arguments and pass these arguments to `apply`.

```
>>> def add_custom_values(x, **kwargs):
...     for month in kwargs:
...         x += kwargs[month]
...     return x
```

```
>>> s.apply(add_custom_values, june=30, july=20, august=25)
London      95
New York    96
Helsinki   87
dtype: int64
```

Use a function from the Numpy library.

```
>>> s.apply(np.log)
London      2.995732
New York    3.044522
Helsinki   2.484907
dtype: float64
```

pandas.Series.argmax

`Series.argmax(axis=None, skipna=True, *args, **kwargs)`

Return int position of the largest value in the Series.

If the maximum is achieved in multiple locations, the first row position is returned.

Parameters

`axis` [{None}] Dummy argument for consistency with Series.

`skipna` [bool, default True] Exclude NA/null values when showing the result.

`*args, **kwargs` Additional arguments and keywords for compatibility with NumPy.

Returns

int Row position of the maximum value.

See also:

[`Series.argmax`](#) Return position of the maximum value.

[`Series.argmin`](#) Return position of the minimum value.

[`numpy.ndarray.argmax`](#) Equivalent method for numpy arrays.

[`Series.idxmax`](#) Return index label of the maximum values.

[`Series.idxmin`](#) Return index label of the minimum values.

Examples

Consider dataset containing cereal calories

```
>>> s = pd.Series({'Corn Flakes': 100.0, 'Almond Delight': 110.0,
...                  'Cinnamon Toast Crunch': 120.0, 'Cocoa Puff': 110.0})
>>> s
Corn Flakes      100.0
Almond Delight   110.0
Cinnamon Toast Crunch  120.0
Cocoa Puff        110.0
dtype: float64
```

```
>>> s.argmax()
2
>>> s.argmin()
0
```

The maximum cereal calories is the third element and the minimum cereal calories is the first element, since series is zero-indexed.

pandas.Series.argmin

[`Series.argmin`\(axis=None, skipna=True, *args, **kwargs\)](#)

Return int position of the smallest value in the Series.

If the minimum is achieved in multiple locations, the first row position is returned.

Parameters

axis [{None}] Dummy argument for consistency with Series.

skipna [bool, default True] Exclude NA/null values when showing the result.

***args, **kwargs** Additional arguments and keywords for compatibility with NumPy.

Returns

int Row position of the minimum value.

See also:

[`Series.argmax`](#) Return position of the maximum value.

`Series.argmax` Return position of the maximum value.

`numpy.ndarray.argmax` Equivalent method for numpy arrays.

`Series.idxmax` Return index label of the maximum values.

`Series.idxmin` Return index label of the minimum values.

Examples

Consider dataset containing cereal calories

```
>>> s = pd.Series({'Corn Flakes': 100.0, 'Almond Delight': 110.0,
...                  'Cinnamon Toast Crunch': 120.0, 'Cocoa Puff': 110.0})
>>> s
Corn Flakes      100.0
Almond Delight   110.0
Cinnamon Toast Crunch  120.0
Cocoa Puff        110.0
dtype: float64
```

```
>>> s.argmax()
2
>>> s.argmin()
0
```

The maximum cereal calories is the third element and the minimum cereal calories is the first element, since series is zero-indexed.

pandas.Series.argsort

`Series.argsort(axis=0, kind='quicksort', order=None)`

Return the integer indices that would sort the Series values.

Override ndarray.argsort. Argsorts the value, omitting NA/null values, and places the result in the same locations as the non-NA values.

Parameters

`axis` [{0 or “index”}] Has no effect but is accepted for compatibility with numpy.

`kind` [{‘mergesort’, ‘quicksort’, ‘heapsort’, ‘stable’}, default ‘quicksort’] Choice of sorting algorithm. See `numpy.sort()` for more information. ‘mergesort’ and ‘stable’ are the only stable algorithms.

`order` [None] Has no effect but is accepted for compatibility with numpy.

Returns

`Series[np.intp]` Positions of values within the sort order with -1 indicating nan values.

See also:

`numpy.ndarray.argsort` Returns the indices that would sort this array.

pandas.Series.asfreq

`Series.asfreq(freq, method=None, how=None, normalize=False, fill_value=None)`

Convert time series to specified frequency.

Returns the original data conformed to a new index with the specified frequency.

If the index of this Series is a `PeriodIndex`, the new index is the result of transforming the original index with `PeriodIndex.asfreq` (so the original index will map one-to-one to the new index).

Otherwise, the new index will be equivalent to `pd.date_range(start, end, freq=freq)` where `start` and `end` are, respectively, the first and last entries in the original index (see `pandas.date_range()`). The values corresponding to any timesteps in the new index which were not present in the original index will be null (`NaN`), unless a method for filling such unknowns is provided (see the `method` parameter below).

The `resample()` method is more appropriate if an operation on each group of timesteps (such as an aggregate) is necessary to represent the data at the new frequency.

Parameters

`freq` [DateOffset or str] Frequency DateOffset or string.

`method` [{‘backfill’/‘bfill’, ‘pad’/‘ffill’}, default `None`] Method to use for filling holes in reindexed Series (note this does not fill NaNs that already were present):

- ‘pad’ / ‘ffill’: propagate last valid observation forward to next valid
- ‘backfill’ / ‘bfill’: use NEXT valid observation to fill.

`how` [{‘start’, ‘end’}, default `end`] For `PeriodIndex` only (see `PeriodIndex.asfreq`).

`normalize` [bool, default `False`] Whether to reset output index to midnight.

`fill_value` [scalar, optional] Value to use for missing values, applied during upsampling (note this does not fill NaNs that already were present).

Returns

`Series` Series object reindexed to the specified frequency.

See also:

`reindex` Conform DataFrame to new index with optional filling logic.

Notes

To learn more about the frequency strings, please see [this link](#).

Examples

Start by creating a series with 4 one minute timestamps.

```
>>> index = pd.date_range('1/1/2000', periods=4, freq='T')
>>> series = pd.Series([0.0, None, 2.0, 3.0], index=index)
>>> df = pd.DataFrame({'s': series})
>>> df
           s
2000-01-01 00:00:00    0.0
```

(continues on next page)

(continued from previous page)

2000-01-01 00:01:00	NaN
2000-01-01 00:02:00	2.0
2000-01-01 00:03:00	3.0

Upsample the series into 30 second bins.

```
>>> df.asfreq(freq='30S')
      S
2000-01-01 00:00:00  0.0
2000-01-01 00:00:30  NaN
2000-01-01 00:01:00  NaN
2000-01-01 00:01:30  NaN
2000-01-01 00:02:00  2.0
2000-01-01 00:02:30  NaN
2000-01-01 00:03:00  3.0
```

Upsample again, providing a `fill` value.

```
>>> df.asfreq(freq='30S', fill_value=9.0)
      S
2000-01-01 00:00:00  0.0
2000-01-01 00:00:30  9.0
2000-01-01 00:01:00  NaN
2000-01-01 00:01:30  9.0
2000-01-01 00:02:00  2.0
2000-01-01 00:02:30  9.0
2000-01-01 00:03:00  3.0
```

Upsample again, providing a `method`.

```
>>> df.asfreq(freq='30S', method='bfill')
      S
2000-01-01 00:00:00  0.0
2000-01-01 00:00:30  NaN
2000-01-01 00:01:00  NaN
2000-01-01 00:01:30  2.0
2000-01-01 00:02:00  2.0
2000-01-01 00:02:30  3.0
2000-01-01 00:03:00  3.0
```

pandas.Series.asof

`Series.asof(where, subset=None)`

Return the last row(s) without any NaNs before `where`.

The last row (for each element in `where`, if list) without any NaN is taken. In case of a `DataFrame`, the last row without NaN considering only the subset of columns (if not `None`)

If there is no good value, NaN is returned for a Series or a Series of NaN values for a DataFrame

Parameters

`where` [date or array-like of dates] Date(s) before which the last row(s) are returned.

subset [str or array-like of str, default *None*] For DataFrame, if not *None*, only use these columns to check for NaNs.

Returns

scalar, Series, or DataFrame The return can be:

- scalar : when *self* is a Series and *where* is a scalar
- Series: when *self* is a Series and *where* is an array-like, or when *self* is a DataFrame and *where* is a scalar
- DataFrame : when *self* is a DataFrame and *where* is an array-like

Return scalar, Series, or DataFrame.

See also:

[merge_asof](#) Perform an asof merge. Similar to left join.

Notes

Dates are assumed to be sorted. Raises if this is not the case.

Examples

A Series and a scalar *where*.

```
>>> s = pd.Series([1, 2, np.nan, 4], index=[10, 20, 30, 40])
>>> s
10    1.0
20    2.0
30    NaN
40    4.0
dtype: float64
```

```
>>> s.asof(20)
2.0
```

For a sequence *where*, a Series is returned. The first value is NaN, because the first element of *where* is before the first index value.

```
>>> s.asof([5, 20])
5      NaN
20    2.0
dtype: float64
```

Missing values are not considered. The following is 2.0, not NaN, even though NaN is at the index location for 30.

```
>>> s.asof(30)
2.0
```

Take all columns into consideration

```
>>> df = pd.DataFrame({'a': [10, 20, 30, 40, 50],
...                      'b': [None, None, None, None, 500]},
...                      index=pd.DatetimeIndex(['2018-02-27 09:01:00',
...                                              '2018-02-27 09:02:00',
...                                              '2018-02-27 09:03:00',
...                                              '2018-02-27 09:04:00',
...                                              '2018-02-27 09:05:00']))
>>> df.asof(pd.DatetimeIndex(['2018-02-27 09:03:30',
...                           '2018-02-27 09:04:30']))
   a    b
2018-02-27 09:03:30  NaN  NaN
2018-02-27 09:04:30  NaN  NaN
```

Take a single column into consideration

```
>>> df.asof(pd.DatetimeIndex(['2018-02-27 09:03:30',
...                           '2018-02-27 09:04:30']),
...           subset=['a'])
   a    b
2018-02-27 09:03:30  30.0  NaN
2018-02-27 09:04:30  40.0  NaN
```

pandas.Series.astype

Series.astype(dtype, copy=True, errors='raise')
Cast a pandas object to a specified dtype dtype.

Parameters

dtype [data type, or dict of column name -> data type] Use a numpy.dtype or Python type to cast entire pandas object to the same type. Alternatively, use {col: dtype, ...}, where col is a column label and dtype is a numpy.dtype or Python type to cast one or more of the DataFrame's columns to column-specific types.

copy [bool, default True] Return a copy when copy=True (be very careful setting copy=False as changes to values then may propagate to other pandas objects).

errors [{‘raise’, ‘ignore’}, default ‘raise’] Control raising of exceptions on invalid data for provided dtype.

- **raise** : allow exceptions to be raised
- **ignore** : suppress exceptions. On error return original object.

Returns

casted [same type as caller]

See also:

[to_datetime](#) Convert argument to datetime.

[to_timedelta](#) Convert argument to timedelta.

[to_numeric](#) Convert argument to a numeric type.

[numpy.ndarray.astype](#) Cast a numpy array to a specified type.

Notes

Deprecated since version 1.3.0: Using `astype` to convert from timezone-naive dtype to timezone-aware dtype is deprecated and will raise in a future version. Use `Series.dt.tz_localize()` instead.

Examples

Create a DataFrame:

```
>>> d = {'col1': [1, 2], 'col2': [3, 4]}
>>> df = pd.DataFrame(data=d)
>>> df.dtypes
col1    int64
col2    int64
dtype: object
```

Cast all columns to int32:

```
>>> df.astype('int32').dtypes
col1    int32
col2    int32
dtype: object
```

Cast col1 to int32 using a dictionary:

```
>>> df.astype({'col1': 'int32'}).dtypes
col1    int32
col2    int64
dtype: object
```

Create a series:

```
>>> ser = pd.Series([1, 2], dtype='int32')
>>> ser
0    1
1    2
dtype: int32
>>> ser.astype('int64')
0    1
1    2
dtype: int64
```

Convert to categorical type:

```
>>> ser.astype('category')
0    1
1    2
dtype: category
Categories (2, int64): [1, 2]
```

Convert to ordered categorical type with custom ordering:

```
>>> from pandas.api.types import CategoricalDtype
>>> cat_dtype = CategoricalDtype(
```

(continues on next page)

(continued from previous page)

```
...     categories=[2, 1], ordered=True)
>>> ser.astype(cat_dtype)
0    1
1    2
dtype: category
Categories (2, int64): [2 < 1]
```

Note that using `copy=False` and changing data on a new pandas object may propagate changes:

```
>>> s1 = pd.Series([1, 2])
>>> s2 = s1.astype('int64', copy=False)
>>> s2[0] = 10
>>> s1 # note that s1[0] has changed too
0    10
1     2
dtype: int64
```

Create a series of dates:

```
>>> ser_date = pd.Series(pd.date_range('20200101', periods=3))
>>> ser_date
0    2020-01-01
1    2020-01-02
2    2020-01-03
dtype: datetime64[ns]
```

pandas.Series.at_time

`Series.at_time(time, asof=False, axis=None)`

Select values at particular time of day (e.g., 9:30AM).

Parameters

`time` [datetime.time or str]
`axis` [{0 or ‘index’, 1 or ‘columns’}, default 0]

Returns

`Series or DataFrame`

Raises

`TypeError` If the index is not a `DatetimeIndex`

See also:

`between_time` Select values between particular times of the day.

`first` Select initial periods of time series based on a date offset.

`last` Select final periods of time series based on a date offset.

`DatetimeIndex.indexer_at_time` Get just the index locations for values at particular time of the day.

Examples

```
>>> i = pd.date_range('2018-04-09', periods=4, freq='12H')
>>> ts = pd.DataFrame({'A': [1, 2, 3, 4]}, index=i)
>>> ts
          A
2018-04-09 00:00:00 1
2018-04-09 12:00:00 2
2018-04-10 00:00:00 3
2018-04-10 12:00:00 4
```

```
>>> ts.at_time('12:00')
          A
2018-04-09 12:00:00 2
2018-04-10 12:00:00 4
```

pandas.Series.autocorr

`Series.autocorr(lag=1)`

Compute the lag-N autocorrelation.

This method computes the Pearson correlation between the Series and its shifted self.

Parameters

`lag` [int, default 1] Number of lags to apply before performing autocorrelation.

Returns

`float` The Pearson correlation between self and self.shift(lag).

See also:

`Series.corr` Compute the correlation between two Series.

`Series.shift` Shift index by desired number of periods.

`DataFrame.corr` Compute pairwise correlation of columns.

`DataFrame.corrwith` Compute pairwise correlation between rows or columns of two DataFrame objects.

Notes

If the Pearson correlation is not well defined return ‘NaN’.

Examples

```
>>> s = pd.Series([0.25, 0.5, 0.2, -0.05])
>>> s.autocorr()
0.10355...
>>> s.autocorr(lag=2)
-0.99999...
```

If the Pearson correlation is not well defined, then ‘NaN’ is returned.

```
>>> s = pd.Series([1, 0, 0, 0])
>>> s.autocorr()
nan
```

pandas.Series.backfill

`Series.backfill(axis=None, inplace=False, limit=None, downcast=None)`

Synonym for `DataFrame.fillna()` with `method='bfill'`.

Returns

`Series/DataFrame or None` Object with missing values filled or None if `inplace=True`.

pandas.Series.between

`Series.between(left, right, inclusive='both')`

Return boolean Series equivalent to `left <= series <= right`.

This function returns a boolean vector containing `True` wherever the corresponding Series element is between the boundary values `left` and `right`. NA values are treated as `False`.

Parameters

`left` [scalar or list-like] Left boundary.

`right` [scalar or list-like] Right boundary.

`inclusive` [{“both”, “neither”, “left”, “right”}] Include boundaries. Whether to set each bound as closed or open.

Changed in version 1.3.0.

Returns

`Series` Series representing whether each element is between left and right (inclusive).

See also:

`Series.gt` Greater than of series and other.

`Series.lt` Less than of series and other.

Notes

This function is equivalent to `(left <= ser) & (ser <= right)`

Examples

```
>>> s = pd.Series([2, 0, 4, 8, np.nan])
```

Boundary values are included by default:

```
>>> s.between(1, 4)
0    True
1   False
2    True
3   False
4   False
dtype: bool
```

With `inclusive` set to "neither" boundary values are excluded:

```
>>> s.between(1, 4, inclusive="neither")
0    True
1   False
2   False
3   False
4   False
dtype: bool
```

`left` and `right` can be any scalar value:

```
>>> s = pd.Series(['Alice', 'Bob', 'Carol', 'Eve'])
>>> s.between('Anna', 'Daniel')
0   False
1    True
2    True
3   False
dtype: bool
```

pandas.Series.between_time

`Series.between_time(start_time, end_time, include_start=False, include_end=False, inclusive=None, axis=None)`

Select values between particular times of the day (e.g., 9:00-9:30 AM).

By setting `start_time` to be later than `end_time`, you can get the times that are *not* between the two times.

Parameters

start_time [datetime.time or str] Initial time as a time filter limit.

end_time [datetime.time or str] End time as a time filter limit.

include_start [bool, default True] Whether the start time needs to be included in the result.

Deprecated since version 1.4.0: Arguments `include_start` and `include_end` have been deprecated to standardize boundary inputs. Use `inclusive` instead, to set each bound as closed or open.

include_end [bool, default True] Whether the end time needs to be included in the result.

Deprecated since version 1.4.0: Arguments `include_start` and `include_end` have been deprecated to standardize boundary inputs. Use `inclusive` instead, to set each bound as closed or open.

inclusive [{“both”, “neither”, “left”, “right”}, default “both”] Include boundaries; whether to set each bound as closed or open.

axis [{0 or ‘index’, 1 or ‘columns’}, default 0] Determine range time on index or columns value.

Returns

Series or DataFrame Data from the original object filtered to the specified dates range.

Raises

TypeError If the index is not a `DatetimeIndex`

See also:

[**at_time**](#) Select values at a particular time of the day.

[**first**](#) Select initial periods of time series based on a date offset.

[**last**](#) Select final periods of time series based on a date offset.

[**DatetimeIndex.indexer_between_time**](#) Get just the index locations for values between particular times of the day.

Examples

```
>>> i = pd.date_range('2018-04-09', periods=4, freq='1D20min')
>>> ts = pd.DataFrame({'A': [1, 2, 3, 4]}, index=i)
>>> ts
          A
2018-04-09 00:00:00  1
2018-04-10 00:20:00  2
2018-04-11 00:40:00  3
2018-04-12 01:00:00  4
```

```
>>> ts.between_time('0:15', '0:45')
          A
2018-04-10 00:20:00  2
2018-04-11 00:40:00  3
```

You get the times that are *not* between two times by setting `start_time` later than `end_time`:

```
>>> ts.between_time('0:45', '0:15')
          A
```

(continues on next page)

(continued from previous page)

```
2018-04-09 00:00:00    1
2018-04-12 01:00:00    4
```

pandas.Series.bfill

`Series.bfill(axis=None, inplace=False, limit=None, downcast=None)`

Synonym for `DataFrame.fillna()` with `method='bfill'`.

Returns

`Series/DataFrame or None` Object with missing values filled or `None` if `inplace=True`.

pandas.Series.bool

`Series.bool()`

Return the bool of a single element Series or DataFrame.

This must be a boolean scalar value, either True or False. It will raise a ValueError if the Series or DataFrame does not have exactly 1 element, or that element is not boolean (integer values 0 and 1 will also raise an exception).

Returns

`bool` The value in the Series or DataFrame.

See also:

`Series.astype` Change the data type of a Series, including to boolean.

`DataFrame.astype` Change the data type of a DataFrame, including to boolean.

`numpy.bool_` NumPy boolean data type, used by pandas for boolean values.

Examples

The method will only work for single element objects with a boolean value:

```
>>> pd.Series([True]).bool()
True
>>> pd.Series([False]).bool()
False
```

```
>>> pd.DataFrame({'col': [True]}).bool()
True
>>> pd.DataFrame({'col': [False]}).bool()
False
```

pandas.Series.cat

Series.cat()

Accessor object for categorical properties of the Series values.

Be aware that assigning to *categories* is a inplace operation, while all methods return new categorical data per default (but can be called with *inplace=True*).

Parameters

data [Series or CategoricalIndex]

Examples

```
>>> s = pd.Series(list("abbccc")).astype("category")
>>> s
0    a
1    b
2    b
3    c
4    c
5    c
dtype: category
Categories (3, object): ['a', 'b', 'c']
```

```
>>> s.cat.categories
Index(['a', 'b', 'c'], dtype='object')
```

```
>>> s.cat.rename_categories(list("cba"))
0    c
1    b
2    b
3    a
4    a
5    a
dtype: category
Categories (3, object): ['c', 'b', 'a']
```

```
>>> s.cat.reorder_categories(list("cba"))
0    a
1    b
2    b
3    c
4    c
5    c
dtype: category
Categories (3, object): ['c', 'b', 'a']
```

```
>>> s.cat.add_categories(["d", "e"])
0    a
1    b
2    b
```

(continues on next page)

(continued from previous page)

```
3    c
4    c
5    c
dtype: category
Categories (5, object): ['a', 'b', 'c', 'd', 'e']
```

```
>>> s.cat.remove_categories(["a", "c"])
0    NaN
1      b
2      b
3    NaN
4    NaN
5    NaN
dtype: category
Categories (1, object): ['b']
```

```
>>> s1 = s.cat.add_categories(["d", "e"])
>>> s1.cat.remove_unused_categories()
0    a
1    b
2    b
3    c
4    c
5    c
dtype: category
Categories (3, object): ['a', 'b', 'c']
```

```
>>> s.cat.set_categories(list("abcde"))
0    a
1    b
2    b
3    c
4    c
5    c
dtype: category
Categories (5, object): ['a', 'b', 'c', 'd', 'e']
```

```
>>> s.cat.as_ordered()
0    a
1    b
2    b
3    c
4    c
5    c
dtype: category
Categories (3, object): ['a' < 'b' < 'c']
```

```
>>> s.cat.as_unordered()
0    a
1    b
2    b
```

(continues on next page)

(continued from previous page)

```

3    c
4    c
5    c
dtype: category
Categories (3, object): ['a', 'b', 'c']

```

pandas.Series.clip

`Series.clip(lower=None, upper=None, axis=None, inplace=False, *args, **kwargs)`

Trim values at input threshold(s).

Assigns values outside boundary to boundary values. Thresholds can be singular values or array like, and in the latter case the clipping is performed element-wise in the specified axis.

Parameters

lower [float or array-like, default None] Minimum threshold value. All values below this threshold will be set to it. A missing threshold (e.g `NA`) will not clip the value.

upper [float or array-like, default None] Maximum threshold value. All values above this threshold will be set to it. A missing threshold (e.g `NA`) will not clip the value.

axis [int or str axis name, optional] Align object with lower and upper along the given axis.

inplace [bool, default False] Whether to perform the operation in place on the data.

***args, **kwargs** Additional keywords have no effect but might be accepted for compatibility with numpy.

Returns

Series or DataFrame or None Same type as calling object with the values outside the clip boundaries replaced or None if `inplace=True`.

See also:

`Series.clip` Trim values at input threshold in series.

`DataFrame.clip` Trim values at input threshold in dataframe.

`numpy.clip` Clip (limit) the values in an array.

Examples

```

>>> data = {'col_0': [9, -3, 0, -1, 5], 'col_1': [-2, -7, 6, 8, -5]}
>>> df = pd.DataFrame(data)
>>> df
   col_0  col_1
0      9     -2
1     -3     -7
2      0      6
3     -1      8
4      5     -5

```

Clips per column using lower and upper thresholds:

```
>>> df.clip(-4, 6)
      col_0  col_1
0       6     -2
1      -3     -4
2       0      6
3      -1      6
4       5     -4
```

Clips using specific lower and upper thresholds per column element:

```
>>> t = pd.Series([2, -4, -1, 6, 3])
>>> t
0    2
1   -4
2   -1
3    6
4    3
dtype: int64
```

```
>>> df.clip(t, t + 4, axis=0)
      col_0  col_1
0       6      2
1      -3     -4
2       0      3
3       6      8
4       5      3
```

Clips using specific lower threshold per column element, with missing values:

```
>>> t = pd.Series([2, -4, np.NaN, 6, 3])
>>> t
0    2.0
1   -4.0
2    NaN
3    6.0
4    3.0
dtype: float64
```

```
>>> df.clip(t, axis=0)
      col_0  col_1
0       9      2
1      -3     -4
2       0      6
3       6      8
4       5      3
```

pandas.Series.combine

`Series.combine(other, func, fill_value=None)`

Combine the Series with a Series or scalar according to *func*.

Combine the Series and *other* using *func* to perform elementwise selection for combined Series. *fill_value* is assumed when value is missing at some index from one of the two objects being combined.

Parameters

other [Series or scalar] The value(s) to be combined with the *Series*.

func [function] Function that takes two scalars as inputs and returns an element.

fill_value [scalar, optional] The value to assume when an index is missing from one Series or the other. The default specifies to use the appropriate NaN value for the underlying dtype of the Series.

Returns

Series The result of combining the Series with the other object.

See also:

`Series.combine_first` Combine Series values, choosing the calling Series' values first.

Examples

Consider 2 Datasets *s1* and *s2* containing highest clocked speeds of different birds.

```
>>> s1 = pd.Series({'falcon': 330.0, 'eagle': 160.0})
>>> s1
falcon    330.0
eagle     160.0
dtype: float64
>>> s2 = pd.Series({'falcon': 345.0, 'eagle': 200.0, 'duck': 30.0})
>>> s2
falcon    345.0
eagle     200.0
duck      30.0
dtype: float64
```

Now, to combine the two datasets and view the highest speeds of the birds across the two datasets

```
>>> s1.combine(s2, max)
duck        NaN
eagle     200.0
falcon    345.0
dtype: float64
```

In the previous example, the resulting value for duck is missing, because the maximum of a NaN and a float is a NaN. So, in the example, we set *fill_value=0*, so the maximum value returned will be the value from some dataset.

```
>>> s1.combine(s2, max, fill_value=0)
duck     30.0
eagle   200.0
```

(continues on next page)

(continued from previous page)

```
falcon    345.0
dtype: float64
```

pandas.Series.combine_first

`Series.combine_first(other)`

Update null elements with value in the same location in ‘other’.

Combine two Series objects by filling null values in one Series with non-null values from the other Series. Result index will be the union of the two indexes.

Parameters

other [Series] The value(s) to be used for filling null values.

Returns

`Series` The result of combining the provided Series with the other object.

See also:

`Series.combine` Perform element-wise operation on two Series using a given function.

Examples

```
>>> s1 = pd.Series([1, np.nan])
>>> s2 = pd.Series([3, 4, 5])
>>> s1.combine_first(s2)
0    1.0
1    4.0
2    5.0
dtype: float64
```

Null values still persist if the location of that null value does not exist in *other*

```
>>> s1 = pd.Series({'falcon': np.nan, 'eagle': 160.0})
>>> s2 = pd.Series({'eagle': 200.0, 'duck': 30.0})
>>> s1.combine_first(s2)
duck      30.0
eagle    160.0
falcon     NaN
dtype: float64
```

`pandas.Series.compare`

`Series.compare(other, align_axis=1, keep_shape=False, keep_equal=False)`

Compare to another Series and show the differences.

New in version 1.1.0.

Parameters

`other` [Series] Object to compare with.

`align_axis` [{0 or ‘index’, 1 or ‘columns’}, default 1] Determine which axis to align the comparison on.

- **0, or ‘index’** [Resulting differences are stacked vertically] with rows drawn alternately from self and other.
- **1, or ‘columns’** [Resulting differences are aligned horizontally] with columns drawn alternately from self and other.

`keep_shape` [bool, default False] If true, all rows and columns are kept. Otherwise, only the ones with different values are kept.

`keep_equal` [bool, default False] If true, the result keeps values that are equal. Otherwise, equal values are shown as NaNs.

Returns

`Series or DataFrame` If axis is 0 or ‘index’ the result will be a Series. The resulting index will be a MultiIndex with ‘self’ and ‘other’ stacked alternately at the inner level.

If axis is 1 or ‘columns’ the result will be a DataFrame. It will have two columns namely ‘self’ and ‘other’.

See also:

`DataFrame.compare` Compare with another DataFrame and show differences.

Notes

Matching NaNs will not appear as a difference.

Examples

```
>>> s1 = pd.Series(["a", "b", "c", "d", "e"])
>>> s2 = pd.Series(["a", "a", "c", "b", "e"])
```

Align the differences on columns

```
>>> s1.compare(s2)
      self  other
1      b      a
3      d      b
```

Stack the differences on indices

```
>>> s1.compare(s2, align_axis=0)
1  self      b
   other     a
3  self      d
   other     b
dtype: object
```

Keep all original rows

```
>>> s1.compare(s2, keep_shape=True)
    self  other
0    NaN    NaN
1      b      a
2    NaN    NaN
3      d      b
4    NaN    NaN
```

Keep all original rows and also all original values

```
>>> s1.compare(s2, keep_shape=True, keep_equal=True)
    self  other
0      a      a
1      b      a
2      c      c
3      d      b
4      e      e
```

pandas.Series.convert_dtypes

`Series.convert_dtypes(infer_objects=True, convert_string=True, convert_integer=True, convert_boolean=True, convert_floating=True)`

Convert columns to best possible dtypes using dtypes supporting `pd.NA`.

New in version 1.0.0.

Parameters

infer_objects [bool, default True] Whether object dtypes should be converted to the best possible types.

convert_string [bool, default True] Whether object dtypes should be converted to `StringDtype()`.

convert_integer [bool, default True] Whether, if possible, conversion can be done to integer extension types.

convert_boolean [bool, defaults True] Whether object dtypes should be converted to `BooleanDtypes()`.

convert_floating [bool, defaults True] Whether, if possible, conversion can be done to floating extension types. If `convert_integer` is also True, preference will be given to integer dtypes if the floats can be faithfully casted to integers.

New in version 1.2.0.

Returns

Series or DataFrame Copy of input object with new dtype.

See also:

[**infer_objects**](#) Infer dtypes of objects.

[**to_datetime**](#) Convert argument to datetime.

[**to_timedelta**](#) Convert argument to timedelta.

[**to_numeric**](#) Convert argument to a numeric type.

Notes

By default, `convert_dtypes` will attempt to convert a Series (or each Series in a DataFrame) to dtypes that support `pd.NA`. By using the options `convert_string`, `convert_integer`, `convert_boolean` and `convert_boolean`, it is possible to turn off individual conversions to `StringDtype`, the integer extension types, `BooleanDtype` or floating extension types, respectively.

For object-dtyped columns, if `infer_objects` is `True`, use the inference rules as during normal Series/DataFrame construction. Then, if possible, convert to `StringDtype`, `BooleanDtype` or an appropriate integer or floating extension type, otherwise leave as `object`.

If the dtype is integer, convert to an appropriate integer extension type.

If the dtype is numeric, and consists of all integers, convert to an appropriate integer extension type. Otherwise, convert to an appropriate floating extension type.

Changed in version 1.2: Starting with pandas 1.2, this method also converts float columns to the nullable floating extension type.

In the future, as new dtypes are added that support `pd.NA`, the results of this method will change to support those new dtypes.

Examples

```
>>> df = pd.DataFrame(  
...     {  
...         "a": pd.Series([1, 2, 3], dtype=np.dtype("int32")),  
...         "b": pd.Series(["x", "y", "z"], dtype=np.dtype("O")),  
...         "c": pd.Series([True, False, np.nan], dtype=np.dtype("O")),  
...         "d": pd.Series(["h", "i", np.nan], dtype=np.dtype("O")),  
...         "e": pd.Series([10, np.nan, 20], dtype=np.dtype("float")),  
...         "f": pd.Series([np.nan, 100.5, 200], dtype=np.dtype("float")),  
...     }  
... )
```

Start with a DataFrame with default dtypes.

```
>>> df  
   a   b     c     d     e     f  
0  1   x   True    h  10.0    NaN  
1  2   y  False    i    NaN  100.5  
2  3   z    NaN  NaN  20.0  200.0
```

```
>>> df.dtypes
a      int32
b      object
c      object
d      object
e    float64
f    float64
dtype: object
```

Convert the DataFrame to use best possible dtypes.

```
>>> dfn = df.convert_dtypes()
>>> dfn
   a   b     c     d     e     f
0  1  x  True     h    10  <NA>
1  2  y  False    i  <NA>  100.5
2  3  z  <NA>  <NA>    20  200.0
```

```
>>> dfn.dtypes
a      Int32
b      string
c     boolean
d      string
e      Int64
f    Float64
dtype: object
```

Start with a Series of strings and missing data represented by `np.nan`.

```
>>> s = pd.Series(["a", "b", np.nan])
>>> s
0      a
1      b
2    NaN
dtype: object
```

Obtain a Series with dtype `StringDtype`.

```
>>> s.convert_dtypes()
0      a
1      b
2    <NA>
dtype: string
```

pandas.Series.copy

`Series.copy(deep=True)`

Make a copy of this object's indices and data.

When `deep=True` (default), a new object will be created with a copy of the calling object's data and indices. Modifications to the data or indices of the copy will not be reflected in the original object (see notes below).

When `deep=False`, a new object will be created without copying the calling object's data or index (only references to the data and index are copied). Any changes to the data of the original will be reflected in the shallow copy (and vice versa).

Parameters

`deep` [bool, default True] Make a deep copy, including a copy of the data and the indices.

With `deep=False` neither the indices nor the data are copied.

Returns

`copy` [Series or DataFrame] Object type matches caller.

Notes

When `deep=True`, data is copied but actual Python objects will not be copied recursively, only the reference to the object. This is in contrast to `copy.deepcopy` in the Standard Library, which recursively copies object data (see examples below).

While `Index` objects are copied when `deep=True`, the underlying numpy array is not copied for performance reasons. Since `Index` is immutable, the underlying data can be safely shared and a copy is not needed.

Examples

```
>>> s = pd.Series([1, 2], index=["a", "b"])
>>> s
a    1
b    2
dtype: int64
```

```
>>> s_copy = s.copy()
>>> s_copy
a    1
b    2
dtype: int64
```

Shallow copy versus default (deep) copy:

```
>>> s = pd.Series([1, 2], index=["a", "b"])
>>> deep = s.copy()
>>> shallow = s.copy(deep=False)
```

Shallow copy shares data and index with original.

```
>>> s is shallow
False
>>> s.values is shallow.values and s.index is shallow.index
True
```

Deep copy has own copy of data and index.

```
>>> s is deep
False
>>> s.values is deep.values or s.index is deep.index
False
```

Updates to the data shared by shallow copy and original is reflected in both; deep copy remains unchanged.

```
>>> s[0] = 3
>>> shallow[1] = 4
>>> s
a    3
b    4
dtype: int64
>>> shallow
a    3
b    4
dtype: int64
>>> deep
a    1
b    2
dtype: int64
```

Note that when copying an object containing Python objects, a deep copy will copy the data, but will not do so recursively. Updating a nested data object will be reflected in the deep copy.

```
>>> s = pd.Series([[1, 2], [3, 4]])
>>> deep = s.copy()
>>> s[0][0] = 10
>>> s
0    [10, 2]
1    [3, 4]
dtype: object
>>> deep
0    [10, 2]
1    [3, 4]
dtype: object
```

pandas.Series.corr

`Series.corr(other, method='pearson', min_periods=None)`

Compute correlation with `other` Series, excluding missing values.

Parameters

`other` [Series] Series with which to compute the correlation.

`method` [{‘pearson’, ‘kendall’, ‘spearman’} or callable] Method used to compute correlation:

- `pearson` : Standard correlation coefficient
- `kendall` : Kendall Tau correlation coefficient
- `spearman` : Spearman rank correlation
- `callable`: Callable with input two 1d ndarrays and returning a float.

Warning: Note that the returned matrix from `corr` will have 1 along the diagonals and will be symmetric regardless of the callable’s behavior.

`min_periods` [int, optional] Minimum number of observations needed to have a valid result.

Returns

`float` Correlation with other.

See also:

`DataFrame.corr` Compute pairwise correlation between columns.

`DataFrame.corrwith` Compute pairwise correlation with another DataFrame or Series.

Examples

```
>>> def histogram_intersection(a, b):
...     v = np.minimum(a, b).sum().round(decimals=1)
...     return v
>>> s1 = pd.Series([.2, .0, .6, .2])
>>> s2 = pd.Series([.3, .6, .0, .1])
>>> s1.corr(s2, method=histogram_intersection)
0.3
```

pandas.Series.count

`Series.count(level=None)`

Return number of non-NA/null observations in the Series.

Parameters

`level` [int or level name, default None] If the axis is a MultiIndex (hierarchical), count along a particular level, collapsing into a smaller Series.

Returns

int or Series (if level specified) Number of non-null values in the Series.

See also:

[`DataFrame.count`](#) Count non-NA cells for each column or row.

Examples

```
>>> s = pd.Series([0.0, 1.0, np.nan])
>>> s.count()
2
```

pandas.Series.cov

`Series.cov(other, min_periods=None, ddof=1)`

Compute covariance with Series, excluding missing values.

Parameters

`other` [Series] Series with which to compute the covariance.

`min_periods` [int, optional] Minimum number of observations needed to have a valid result.

`ddof` [int, default 1] Delta degrees of freedom. The divisor used in calculations is $N - ddof$, where N represents the number of elements.

New in version 1.1.0.

Returns

float Covariance between Series and other normalized by N-1 (unbiased estimator).

See also:

[`DataFrame.cov`](#) Compute pairwise covariance of columns.

Examples

```
>>> s1 = pd.Series([0.90010907, 0.13484424, 0.62036035])
>>> s2 = pd.Series([0.12528585, 0.26962463, 0.51111198])
>>> s1.cov(s2)
-0.01685762652715874
```

pandas.Series.cummax

Series.cummax(axis=None, skipna=True, *args, **kwargs)

Return cumulative maximum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative maximum.

Parameters

axis [{0 or ‘index’, 1 or ‘columns’}, default 0] The index or the name of the axis. 0 is equivalent to None or ‘index’.

skipna [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

***args, **kwargs** Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

scalar or Series Return cumulative maximum of scalar or Series.

See also:

[core.window.Expanding.max](#) Similar functionality but ignores NaN values.

[Series.max](#) Return the maximum over Series axis.

[Series.cummax](#) Return cumulative maximum over Series axis.

[Series.cummin](#) Return cumulative minimum over Series axis.

[Series.cumsum](#) Return cumulative sum over Series axis.

[Series.cumprod](#) Return cumulative product over Series axis.

Examples

Series

```
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1    NaN
2    5.0
3   -1.0
4    0.0
dtype: float64
```

By default, NA values are ignored.

```
>>> s.cummax()
0    2.0
1    NaN
2    5.0
3    5.0
4    5.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```
>>> s.cummax(skipna=False)
0    2.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

DataFrame

```
>>> df = pd.DataFrame([[2.0, 1.0],
...                     [3.0, np.nan],
...                     [1.0, 0.0]],
...                     columns=list('AB'))
>>> df
   A    B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

By default, iterates over rows and finds the maximum in each column. This is equivalent to `axis=None` or `axis='index'`.

```
>>> df.cummax()
   A    B
0  2.0  1.0
1  3.0  NaN
2  3.0  1.0
```

To iterate over columns and find the maximum in each row, use `axis=1`

```
>>> df.cummax(axis=1)
   A    B
0  2.0  2.0
1  3.0  NaN
2  1.0  1.0
```

`pandas.Series.cummin`

`Series.cummin(axis=None, skipna=True, *args, **kwargs)`

Return cumulative minimum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative minimum.

Parameters

`axis` [{0 or ‘index’, 1 or ‘columns’}, default 0] The index or the name of the axis. 0 is equivalent to None or ‘index’.

`skipna` [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

`*args, **kwargs` Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

`scalar or Series` Return cumulative minimum of scalar or Series.

See also:

`core.window.Expanding.min` Similar functionality but ignores NaN values.

`Series.min` Return the minimum over Series axis.

`Series.cummax` Return cumulative maximum over Series axis.

`Series.cummin` Return cumulative minimum over Series axis.

`Series.cumsum` Return cumulative sum over Series axis.

`Series.cumprod` Return cumulative product over Series axis.

Examples

Series

```
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1    NaN
2    5.0
3   -1.0
4    0.0
dtype: float64
```

By default, NA values are ignored.

```
>>> s.cummin()
0    2.0
1    NaN
2    2.0
3   -1.0
4   -1.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```
>>> s.cummin(skipna=False)
0    2.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

DataFrame

```
>>> df = pd.DataFrame([[2.0, 1.0],
...                     [3.0, np.nan],
...                     [1.0, 0.0]],
...                     columns=list('AB'))
>>> df
   A    B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

By default, iterates over rows and finds the minimum in each column. This is equivalent to `axis=None` or `axis='index'`.

```
>>> df.cummin()
   A    B
0  2.0  1.0
1  2.0  NaN
2  1.0  0.0
```

To iterate over columns and find the minimum in each row, use `axis=1`

```
>>> df.cummin(axis=1)
   A    B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

pandas.Series.cumprod

`Series.cumprod(axis=None, skipna=True, *args, **kwargs)`

Return cumulative product over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative product.

Parameters

`axis` [{0 or ‘index’, 1 or ‘columns’}, default 0] The index or the name of the axis. 0 is equivalent to None or ‘index’.

`skipna` [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

`*args, **kwargs` Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

scalar or Series Return cumulative product of scalar or Series.

See also:

`core.window.Expanding.prod` Similar functionality but ignores NaN values.

`Series.prod` Return the product over Series axis.

`Series.cummax` Return cumulative maximum over Series axis.

`Series.cummin` Return cumulative minimum over Series axis.

`Series.cumsum` Return cumulative sum over Series axis.

`Series.cumprod` Return cumulative product over Series axis.

Examples

Series

```
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1    NaN
2    5.0
3   -1.0
4    0.0
dtype: float64
```

By default, NA values are ignored.

```
>>> s.cumprod()
0    2.0
1    NaN
2   10.0
3  -10.0
4   -0.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```
>>> s.cumprod(skipna=False)
0    2.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

DataFrame

```
>>> df = pd.DataFrame([[2.0, 1.0],
...                     [3.0, np.nan],
...                     [1.0, 0.0]],
...                     columns=list('AB'))
>>> df
```

(continues on next page)

(continued from previous page)

	A	B
0	2.0	1.0
1	3.0	NaN
2	1.0	0.0

By default, iterates over rows and finds the product in each column. This is equivalent to `axis=None` or `axis='index'`.

```
>>> df.cumprod()
      A      B
0  2.0  1.0
1  6.0  NaN
2  6.0  0.0
```

To iterate over columns and find the product in each row, use `axis=1`

```
>>> df.cumprod(axis=1)
      A      B
0  2.0  2.0
1  3.0  NaN
2  1.0  0.0
```

pandas.Series.cumsum

`Series.cumsum(axis=None, skipna=True, *args, **kwargs)`

Return cumulative sum over a DataFrame or Series axis.

Returns a DataFrame or Series of the same size containing the cumulative sum.

Parameters

`axis` [{0 or ‘index’, 1 or ‘columns’}, default 0] The index or the name of the axis. 0 is equivalent to None or ‘index’.

`skipna` [bool, default True] Exclude NA/null values. If an entire row/column is NA, the result will be NA.

`*args, **kwargs` Additional keywords have no effect but might be accepted for compatibility with NumPy.

Returns

`scalar or Series` Return cumulative sum of scalar or Series.

See also:

`core.window.Exploding.sum` Similar functionality but ignores NaN values.

`Series.sum` Return the sum over Series axis.

`Series.cummax` Return cumulative maximum over Series axis.

`Series.cummin` Return cumulative minimum over Series axis.

`Series.cumsum` Return cumulative sum over Series axis.

`Series.cumprod` Return cumulative product over Series axis.

Examples

Series

```
>>> s = pd.Series([2, np.nan, 5, -1, 0])
>>> s
0    2.0
1    NaN
2    5.0
3   -1.0
4    0.0
dtype: float64
```

By default, NA values are ignored.

```
>>> s.cumsum()
0    2.0
1    NaN
2    7.0
3    6.0
4    6.0
dtype: float64
```

To include NA values in the operation, use `skipna=False`

```
>>> s.cumsum(skipna=False)
0    2.0
1    NaN
2    NaN
3    NaN
4    NaN
dtype: float64
```

DataFrame

```
>>> df = pd.DataFrame([[2.0, 1.0],
...                     [3.0, np.nan],
...                     [1.0, 0.0]],
...                     columns=list('AB'))
>>> df
   A    B
0  2.0  1.0
1  3.0  NaN
2  1.0  0.0
```

By default, iterates over rows and finds the sum in each column. This is equivalent to `axis=None` or `axis='index'`.

```
>>> df.cumsum()
      A    B
0  2.0  1.0
1  5.0  NaN
2  6.0  1.0
```

To iterate over columns and find the sum in each row, use `axis=1`

```
>>> df.cumsum(axis=1)
      A    B
0   2.0  3.0
1   3.0  NaN
2   1.0  1.0
```

pandas.Series.describe

`Series.describe(percentiles=None, include=None, exclude=None, datetime_is_numeric=False)`

Generate descriptive statistics.

Descriptive statistics include those that summarize the central tendency, dispersion and shape of a dataset's distribution, excluding `NaN` values.

Analyzes both numeric and object series, as well as `DataFrame` column sets of mixed data types. The output will vary depending on what is provided. Refer to the notes below for more detail.

Parameters

percentiles [list-like of numbers, optional] The percentiles to include in the output. All should fall between 0 and 1. The default is [.25, .5, .75], which returns the 25th, 50th, and 75th percentiles.

include ['all', list-like of dtypes or None (default), optional] A white list of data types to include in the result. Ignored for `Series`. Here are the options:

- 'all' : All columns of the input will be included in the output.
- A list-like of dtypes : Limits the results to the provided data types. To limit the result to numeric types submit `numpy.number`. To limit it instead to object columns submit the `numpy.object` data type. Strings can also be used in the style of `select_dtypes` (e.g. `df.describe(include=['O'])`). To select pandas categorical columns, use 'category'
- None (default) : The result will include all numeric columns.

exclude [list-like of dtypes or None (default), optional] A black list of data types to omit from the result. Ignored for `Series`. Here are the options:

- A list-like of dtypes : Excludes the provided data types from the result. To exclude numeric types submit `numpy.number`. To exclude object columns submit the data type `numpy.object`. Strings can also be used in the style of `select_dtypes` (e.g. `df.describe(exclude=['O'])`). To exclude pandas categorical columns, use 'category'
- None (default) : The result will exclude nothing.
